TARQUINIUS PRISCUS, LUCIUS, fifth legendary king of Rome (616–578 B.C.). He is represented as the son of a Greek refugee, who removed from Tarquinii in Etruria to Rome, by the advice of his wife, the prophetess Tanaquil. Appointed guardian to the sons of Ancus Marcius, he succeeded in supplanting them on the throne on their father's death. He laid out the Circus Maximus, instituted the "great" games, built the great sewers (*cloacae*), and began the construction of the temple of Jupiter on the Capitol. He carried on war successfully against the Sabines and subjugated Latium. He is said to have raised the number of the senators to 300, and to have doubled the number of the knights (see NAVIUS, ATTUS). The introduction of many of the insignia both of war and of civil office is assigned to his reign, and he was the first to celebrate a Roman triumph, after the Etruscan fashion, in a robe of purple and gold, and borne on a chariot drawn by four horses. He was assassinated at the instigation of the sons of Ancus Marcius.

The legend of Tarquinius Priscus is in the main a reproduction of those of Romulus and Tullus Hostilius. His Corinthian descent, invented by the Greeks to establish a close connexion with Rome, is impossible for chronological reasons; further, according to the genuine Roman tradition, the Tarquinii were of Etruscan, not Greek, origin. There seems to have been originally only one Tarquinius; later, when a connected story of the legendary period was constructed, two (distinguished as the "Elder" and the "Proud") were introduced, separated by the reign of Servius Tullius, and the name of both was connected with the same events. Thus, certain public works were said to have been begun by the earlier and finished by the later king; both instituted games, acquired the Sibylline books, and reorganized the army.

For the constitutional reforms attributed to Tarquinius, see ROME: *Ancient History*; for a critical examination of the story, Schwegler, *Römische Geschichte*, bk. xv.; Sir George Cornewall Lewis, *Credibility of early Roman History*, ch. 11; W. Ihne, *History of Rome*, i.; E. Pais, *Storia di Roma*, i. (1898), who identifies Tarquinius with Tarpeius, the eponymus of the Tarpeian rock, subsequently developed into the wicked king Tarquinius Superbus. Ancient authorities:—Livy i. 34–41; Dion. Hal. iii. 46–73; Cic. *de Repub.*, ii. 200.

TARQUINIUS SUPERBUS, LUCIUS, son of Lucius Tarquinius Priscus and son-in-law of Servius Tullius, the seventh and last legendary king of Rome (534–510 B.C.). On his accession he proceeded at once to repeal the recent reforms in the constitution, and attempted to set up a pure despotism. Many senators were put to death, and their places remained unfilled; the lower classes were deprived of their arms and employed in erecting splendid monuments, while the army was recruited from the king's own retainers and from the forces of foreign allies. The completion of the fortress-temple on the Capitoline confirmed his authority over the city, and a fortunate marriage of his son to the daughter of Octavius Mamilius of Tusculum secured him powerful assistance in the field. His reign was characterized by bloodshed and violence; the outrage of his son Sextus upon Lucretia (*q.v.*) precipitated a revolt, which led to the expulsion of the entire family. All Tarquinius's efforts to force his way back to the throne were vain (see PORSENA), and he died in exile at Cumae.

In the story certain Greek elements, probably later additions, may easily be distinguished. Tarquinius appears as a Greek "tyrant" of the ordinary kind, who surrounds himself with a bodyguard and erects magnificent buildings to keep the people employed; on the other hand, an older tradition represents him as more like Romulus. This twofold aspect of his character perhaps accounts for the making of two Tarquinii out of one (see TARQUINIUS PRISCUS). The stratagem by which Tarquinius obtained possession of the town of Gabii is a mere fiction, derived from Greek and Oriental sources. According to arrangement, his son Sextus requested the protection of the inhabitants against his father. Having obtained their confidence, he sent a messenger to Tarquinius to inquire the next step. His father made no reply to the messenger, but walked up and down his garden, striking off the heads of the tallest poppies. Sextus thereupon put to death all the chief men of the town, and thus obtained the mastery. The stratagem of Sextus is that practised by Zopyrus is the case of Babylon, while the episode of the poppy-heads is borrowed from the advice given by Thrasybulus to Periander (Herodotus iii. 154, v. 92). On the other hand, the existence in the time of Dionysius of Halicarnassus of a treaty concluded between Tarquinius and the inhabitants of Gabii, shows that the town came under his dominion by formal agreement, not, as the tradition states, by treachery and violence. The embassy to Delphi (see BRUTUS, LUCIUS JUNIUS) cannot be historical, since at the time there was no communication between Rome and the mainland of Greece. The well-known story of Tarquinius's repeated refusal and final consent to purchase the Sibylline books has its origin in the fact that the building of the temple of Jupiter Capitolinus, in which they were kept, was ascribed to him. The traditional account of his expulsion can hardly be historical. A constitutional revolution, involving such far-reaching changes, is not likely to have been carried out in primitive times with so little disturbance by a simple resolution of the people, and it probably points to a rising of Romans and Sabines against the dominion of an Etruscan family (Tarquinii, Tarchna) at that time established at Rome.

For a critical examination of the story see Schwegler, *Römische Geschichte*, bk. xviii.; Sir G. Cornewall Lewis, *Credibility of early Roman History*, ch. 11; E. Pais, *Storia di Roma*, i. (1898); and, for the political character of his reign, ROME: *Ancient History*. Ancient authorities:—Livy i. 21; Dion. Hal. v. 1–vi. 21.

TARRAGONA, a maritime province in the north-east of Spain, formed in 1833 from the southern part of the province of Catalonia, and bounded on the S.E. by the Mediterranean, N.E. by Barcelona, N. by Lerida, W. by Saragossa and Teruel, and S.W. by Castellon de la Plana. Pop. (1900) 337,964; area, 2505 sq. m. The Ebro flows through the southern portion of the province, and the other chief streams are the Gaya and the Francoli. These three rivers flow south into the Mediterranean. Below Tortosa, the Ebro forms a conspicuous marshy delta jutting out into the sea, but elsewhere the even south-westward curve of the coast-line is unbroken by any noteworthy headland or indentation. The province, although mountainous, is naturally fertile. The hills are clothed with vineyards, which produce excellent wines, and in the valleys are cultivated all kinds of grain, vegetables, rice, hemp, flax and silk. Olive, orange, filbert and almond trees reach great perfection, and the mountains yield rich pastures and timber trees of various kinds. The climate is temperate on the coast and in the centre, cold in the highlands, very warm and damp in the valleys and on the banks of the rivers as they near the sea. Manufactures are well advanced, and comprise silk, cotton, linen and woollen fabrics, velvet, felt, soap, leather and spirits. There are also many potteries and cooperages, and flour, paper and oil mills. Silver, copper, lead and other minerals have been found, and quarries of marble and jasper are worked in the hills. The fisheries produce more than £20,000 yearly. There are upwards of 250 m. of railways, which link together all the large towns, and include the important main lines along the coast and up the Ebro valley. The cities of Tarragona (pop., 1900, 23,423) and Tortosa (24,452), which are the principal seaports, and the towns of Reus (26,681) and Valls (12,625) are described in separate articles. Montblanch (5243) is the only other town with a population exceeding 5000. The people of Tarragona are, like almost all the inhabitants of Catalonia (*q.v.*), hardy, enterprising and industrious. Although the birth-rate considerably exceeds the death-rate, the population tends to decrease slightly, as many families emigrate.

TARRAGONA (anc. *Tarraco*), the capital of the Spanish province of Tarragona, a flourishing seaport, and the seat of an archbishop; at the mouth of the river Francoli, 63 m. by rail W.S.W. of Barcelona, in 41° 10′ N. and 0° 20′ E. Pop. (1900) 23,423. Tarragona is on the coast railway from Barcelona to Valencia, and is connected with the Ebro Valley Railway by a branch line to Reus. The picturesque old town, with its dark and steep alleys, occupies a rugged hill which rises abruptly from the sea to an altitude of about 550 ft. Its highest point, where the ancient citadel stood, is crowned by the cathedral, the seminary for priests, and the palace of the archbishop, who shares the title primate of Spain with the archbishop of Toledo. Many of the houses in this quarter are very old, and are built partly of Roman masonry; one such fragment, immured in the palace wall, is inscribed with the epitaph of a charioteer (*auriga*) who, it says, would rather have died in the circus than of fever. Massive ruined walls encircle the old town. Their lowest course is "Cyclopean," consisting of unhewn blocks about 12 ft. long and 6 ft. wide; Roman masonry of the Augustan age is superimposed. The six gates and the square towers are also, to a great extent, "Cyclopean." The palace, itself a building of the early 19th century, has an old fortified tower, and there are barracks and forts in the city; but Tarragona can no longer be regarded as a fortress capable of withstanding modern artillery, although it is officially classed as such.

The new town, divided from the old by one broad and shady avenue, the Rambla de San Carlos, and intersected by another, the more modern Rambla de San Juan, extends to the west and south along a low promontory which juts out into the Mediterranean. Its outlying districts merge into the Camp de Tarragona, a plain planted with vines and walnut, almond and olive groves. Tarragona cathedral is one of the noblest examples of early Spanish art. It is 320 ft. long and 103 ft. broad, and consisted originally of a nave, aisles, transepts with an octagonal lantern at the crossing, and an apsidal chancel. Several exterior chapels were added in later times, and on the south-east stands a 14th-century steeple raised on a Romanesque tower. The east end was probably begun in 1131 on the ruins of an earlier church, but the main body of the building dates from the end of the 12th century and the first half of the 13th, and is of transitional character,—the exuberant richness of the sculptured capitals being admirably kept in subordination by the Romanesque simplicity of the general design. Considerable changes were introduced at a later date; and the present west end of the nave cannot have been completed till late in the 14th century. On the north-east side is a cloister contemporary with the church, with which it communicates by a very fine doorway. The cloister contains much remarkable work, and the tracery of the windows bears interesting marks of Moorish influence. Two other noteworthy churches in the city are San Pablo and Santa Tecla la Vieja, both of the 12th century. There is a fine Roman aqueduct; the Roman amphitheatre was dismantled in 1491 to furnish stone for the eastern mole, though a few rows of seats are left near the sea-shore; and the museum contains a large collection of Roman antiquities. The Torreón de Pilatos is said to have been the palace of the Emperor Augustus; it was partly destroyed by the French in 1811 and now serves as a prison. Its name is connected with an old tradition that Pontius Pilate was a native of the city. Tarragona has also many public buildings, including the law courts, several hospitals, a provincial institute, training schools for teachers, and offices of the provincial and municipal governments. When the monks of the Grande Chartreuse were compelled to leave France, they settled at Tarragona in 1903, and established a liqueur factory; 20,000 cases of liqueur were exported in 1904 and 39,000 in 1905. A characteristic feature of Tarragona is the number of its underground storehouses for wine (bodegas); wine is exported in large quantities. There is a British steel file factory; chocolate, soap, flour, ironware, paper, pipes and salted fish are also manufactured. The harbour is at the extreme south-west of the new town. It was originally protected by a Roman breakwater, which was destroyed in the 19th century. The eastern mole, founded in 1491 and frequently enlarged, terminates in a lighthouse. Its length was 1400 yards in 1904, when the construction of a new section was begun. In each of the five years 1901–5 about 870 ships of 580,000 tons entered the port. Wine, oil, nuts, almonds and small quantities of lead and pig iron are exported; the imports include coal from Great Britain, grain from the Black Sea, staves and petroleum from the United States, dried codfish from Norway and Iceland, guano and phosphates. Close to the harbour and at the mouth of the Francoli is the fishermen's quarter (*barrio de pescadores*), in which most of the houses are coloured pale blue.

History.—Tarraco, the capital of the Iberian Cessetani, many of whose coins are extant, was one of the earliest Roman strongholds in Spain. It was captured in 218 B.C. by Gnaeus and Publius Cornelius Scipio, who improved its harbours and enlarged its walls. A Roman monument on a hill 3 m. E. is known as the Sepulcro de los Escipiones, and locally believed to be the tomb of the Scipios, who were defeated and slain by the Carthaginians under Hasdrubal Barca in 212 B.C. The battle took place at Antiorgis, the modern Alcañiz in the province of Teruel; there is no good reason to believe that the bodies of the Scipios were conveyed to Tarragona for burial, nor is the monument older than the 1st century A.D. As the Colonia Triumphalis, so called to commemorate the victories of Julius Caesar, Tarraco was made the seat of one of the four assize courts (*conventus juridici*) established in Hispania Citerior. Augustus spent the winter of 26 B.C. here, and made Tarraco the capital of the whole province, which received the name of Hispania Tarraconensis. A temple was built in his honour. It was afterwards restored by Hadrian (A.D. 117–138), and the city became the Spanish headquarters of the worship of the goddess Roma and the deified emperors. Its flax trade and other industries made it one of the richest seaports of the empire; Martial and Pliny celebrated its climate and its wines, and the fragmentary remains of temples, baths, amphitheatre and other Roman buildings bear witness to its prosperity. It became an archbishopric in the 5th century.

To the Romans the Visigoths under Euric succeeded in 467, but on their expulsion by the Moors in 711 the city was plundered and burned. It was long before the ruins were again inhabited, but by 1089, when the Moors were driven out by Raymond IV. of Barcelona, there must have been a certain revival of prosperity, for the primacy, which had been removed to Vich, was in that year restored to Tarragona. In 1118 a grant of the fief was made to the Norman Robert Burdet, who converted the town into a frontier fortress against the Moors. In 1705 the city was taken and burned by the British; in 1811, after being partly fortified, it was captured and sacked by the French.

TARRASA, a town of north-eastern Spain, in the province of Barcelona, 6 m. W.N.W. of Sabadell on the Barcelona-Lérida railway, and in the midst of a narrow plain surrounded by mountains. Pop. (1900) 15,956. Tarrasa was a Roman municipality, and a bishopric from the 5th century to the Moorish invasion in the 8th. It was razed by the Moors and rebuilt later by the Christians. There are three ancient Romanesque churches, in one of which, San Miguel, some Roman pillars are incorporated. Tarrasa is now mostly a modern industrial town, with fine public buildings, including the royal college, built in 1864 for 450 students besides day scholars, the school of arts and handicrafts, the industrial institute, chamber of commerce, hospitals, town hall, clubs, theatres and many large textile factories. Grain, wine, oil and fruit are produced in the district, and there is a municipal farm, founded in 1885, for experiments in viticulture.

TARRING AND FEATHERING, a method of punishment at least as old as the Crusades. The head of the culprit was shaved and hot tar poured over it, a bag of feathers being afterwards shaken over him. The earliest mention of the punishment occurs in the orders of Richard Cœur de Lion, issued to his navy on starting for the Holy Land in 1191. "Concerning the lawes and ordinances appointed by King Richard for his navie the forme thereof was this . . . item, a thiefe or felon that hath stolen, being lawfully convicted, shal have his head shorne, and boyling pitch poured upon his head, and feathers or downe strawed upon the same whereby he may be knowen, and so at the first landing-place they shall come to, there to be cast up" (trans. of original statute in *Hakluyt's Voyages*, ii. 21). A later instance of this penalty being inflicted is given in *Notes and Queries* (series 4, vol. v.), which quotes one James Howell writing from Madrid, in 1623, of the "boisterous Bishop of Halverstadt," who, "having taken a place where there were two monasteries of nuns and friars, he caused divers feather beds to be ripped, and all the feathers thrown into a great hall, whither the nuns and friars were thrust naked with their bodies oiled and pitched and to tumble among these feathers, which makes them here (Madrid) presage him an ill-death." In 1696 a London bailiff, who attempted to serve process on a debtor who had taken refuge within the precincts of the Savoy, was tarred and feathered and taken in a wheelbarrow to the Strand, where he was tied to the Maypole which stood by what is now Somerset House. It is probable that the punishment was never regarded as legalized, but was always a type of mob vengeance.

TARRYTOWN, a village of Westchester county, New York, on the E. bank of the Hudson river, opposite Nyack, with which it is connected by ferry, and about 25 m. N. of New York City. Pop. (1890) 3562; (1900) 4770, of whom 984 were foreign-born and 191 were negroes; (1910, U.S. census) 5600. Tarrytown is served by the New York Central and Hudson River railway, and by interurban electric lines connecting it, via White Plains, with New York City. It is situated on a sloping hill that rises to a considerable height above Tappan Zee, a large expansion of the Hudson river, and is built principally along either side of a broad and winding country highway (laid out in 1723) from New York to Albany, called the King's Highway until the War of Independence, then called the Albany Post Road, and now known (in Tarrytown) as Broadway. South of the village is "Lyndhurst," the estate of Miss Helen Miller Gould, and to the N.E. is Kaakout (originally "Kijkuit," that is, "lookout," the name of a high promontory), the estate of John D. Rockefeller. In the village are the Hackley School (1899), Irving School (1837), Repton School and the "Castle" School for girls; a Young Men's Lyceum (1899), with a public library (8000 volumes in 1910) and the Tarrytown Hospital (1892). In the vicinity there are large nurseries and market-gardens, and automobiles are manufactured in the village. Tarrytown stands on the site of a Wecquaesgeek Indian village, Alipconk (the place of elms), burned by the Dutch in 1644. The first settlement of whites was made about 1645. There were perhaps a dozen Dutch families here in 1680, when Frederick Philipse (formerly known as Vredryk Flypse) acquired title to several thousand acres in Westchester county, called Philipse Manor. He built, partly of brick brought from Holland, a manor-house (on a point of land now known as Kingsland's Point, a short distance above the present village), a mill and a church, at the mouth of Sleepy Hollow, some three-quarters of a mile above the village; Dr Hamilton Wright Mabie has written: "There is probably no other locality in America, taking into account history, tradition, the old church, the manor-house and the mill, which so entirely conserves the form and spirit of Dutch civilization in the New World." During the War of Independence Tarrytown was the centre of the "Neutral Territory" between the lines of the British and Continental forces, and was the scene of numerous conflicts between the "cowboys" and "skinners," bands of unorganized partisans, the former acting in the name of the colonies, and the latter in that of the king. On the post road, on the 24th of September 1780, Major John André was captured by three Continentals, John Paulding, David Williams and Isaac Van Wert; to commemorate the capture a marble shaft surmounted by a bronze statue of a Continental soldier has been erected on the spot. Tarrytown is described in the *Sketch Book* of Washington Irving, who lived and died at "Sunnyside," within the limits of Tarrytown, was long warden of old Christ Church, and is buried in the Old Sleepy Hollow burying-ground, which adjoins the Dutch Church, and in which Carl Schurz also is buried. Tarrytown was incorporated as a village in 1870. Its name is probably a corrupt form of the Dutch "Tarwen dorp" (wheat town).

See H. B. Dawson, *Westchester County in the American Revolution* (New York, 1886); and an article by H. W. Mabie in L. P. Powell's *Historic Towns of the Middle States* (New York, 1899).

TARSIER, the Anglicized form of the scientific name of a small and aberrant lemur-like animal, *Tarsius spectrum*, inhabiting the Malay Peninsula and islands, and typifying a family. The name tarsier refers to the great elongation of two of the bones of the tarsus, or ankle, and *spectrum* to the huge goggle-like eyes and attenuated form which constitute two of the most distinctive features of this weird little creature. In organization the tarsier departs markedly from other lemurs as regards several particulars, and thereby approximates to monkeys and apes. Rather smaller than a squirrel, with dusky brown fur, the tarsier has immense eyes, large ears, a long thin tail, tufted at the end, a greatly elongated tarsal portion of the foot, and disk-like adhesive surfaces on the fingers, which doubtless assist the animal in maintaining its position on the boughs. Four species of the genus are now recognized, whose range includes the Malay Peninsula, Java, Sumatra, Borneo, Celebes and some of the Philippines. The tarsier feeds chiefly on insects and lizards, sleeps during the day, but is tolerably active at night, moving chiefly by jumping from place to place; an action for which the structure of its hind-legs seems particularly well adapted. It is rare, not more than two being generally found together, and only brings forth one young at a time. (See PRIMATES.) (R. L.*)

TARSUS (mod. *Tersous*), an ancient city in the fertile plain of Cilicia. The small river Cydnus flowed through the centre of the town, and its cool swift waters were the boast of the city (though visitors like Dion Chrysostom thought it far inferior to the rivers of many Greek cities). The harbour, Rhegma, below the city, was originally a lagoon, though it is said also to be supplied by springs of its own. The Cydnus flowed into the lake (where were the arsenals) and thence into the sea, about 10 m. from Tarsus. The city is first mentioned on the Black Obelisk, as captured by the Assyrians along with the rest of Cilicia about 850 B.C. It was probably an old Ionian colony, settled (like Mallus) under the direction of Clarian Apollo. Its importance was due (1) to its excellent and safe harbour, (2) to its possession of a fertile territory, and (3) to its command of the first waggon-road made across Mount Taurus, which was cut through the Cilician Gates, a narrow gorge 100 yards in length, originally only wide enough to carry the waters of a small affluent of the Cydnus. The greatness of Tarsus rested therefore mainly on the two great engineering works, the harbour and the road. That the latter was due to Greek influence is shown by the village Mopsucrene on the southern approach to the Gates: Mopsus was the prophet of Clarian Apollo. Few mountain passes have been so important in history as this road (seventy miles in length) over Taurus. Many armies have marched over it; those of Cyrus the Younger, Alexander the Great, Cicero, Septimius Severus and the First Crusade may specially be mentioned.

Tarsus is most accessible from the sea or from the east. Even after the "Cilician Gates" were cut, the crossing of Taurus was a difficult operation for an invading army (as Xenophon and Arrian show). Hence Tarsian history (where not determined by Greek maritime relations) has been strongly affected by Semitic influence, and Dion Chrysostom, about A.D. 112, says it was more like a Phoenician than a Hellenic city (which it claimed to be). After the Assyrian power decayed, princes, several of whom bore the name or title Syennesis, ruled Tarsus before and under Persian power. Persian satraps governed it in the 4th century B.C.; and struck coins with Aramaic legends there. The Seleucid kings of Syria for a time kept it in a state of servitude; but it was made an autonomous city with additional citizens (probably Argive Greeks and Jews) by Antiochus IV. Epiphanes in 171 B.C.; and then it began to strike its own coins. It became one of the richest and greatest cities of the East under the Romans after 104 B.C., and was favoured by both Antony and Augustus: the reception there by the former of Cleopatra, who sailed up to the city in a magnificent vessel, was a striking historic event. In spite of its oriental character, it maintained a university where Greek philosophy was taught by a series of famous Tarsians, who influenced Roman history. Chief among them was Athenodorus Cananites (*q.v.*), teacher and friend of Augustus for many years, a man of courage and power, who remodelled the Tarsian constitution (making it timocratic and oligarchic). The picture which Philostratus, in his biography of Apollonius Tyanensis, draws of the Tarsians as vain, luxurious and illiterate, represents the general Graeco-Roman conception of the city. The legend which was believed to be graven on the statue of Sardanapalus at Anchiale (12 m. S.W. from Tarsus) might have been the motto of most Tarsians: "Eat, drink, play, for nothing else is worth this (gesture)" (referred to by St Paul, 1 Cor. xv. 32). The statue was probably an archaic work, with Hittite or cuneiform inscription, representing a figure with right hand raised: the letters and the attitude were misunderstood; the figure was supposed to be snapping the fingers and uttering this expression of effeminate and weary sensualism.

Tarsus depended for its greatness on commerce, peace and orderly government. It was not a strong fortress, and could not be defended during the decay of the empire against barbarian invasion. The Arabs captured the whole of Cilicia shortly after A.D. 660; and Tarsus seems to have been a ruin for more than a century after the conquest. But Harun al-Rashid rebuilt its walls in 787, and made it the north-western capital of the Arab power in the long wars against the Byzantine empire. All the raids, which were made in Asia Minor regularly, year by year, sometimes twice in one year, through the Cilician Gates and past the fortress Loulon, issued through the north gate of Tarsus, which was called the "Gate of the Holy War." The western gate is still standing, and is misnamed "St Paul's Gate." The caliph Mamun died on such a foray in A.D. 833, having caught a chill at a great spring north of the Cilician Gates beside Ak-Keupreu. He was brought to Tarsus where (like the emperor Tacitus) he died, and (like the emperor Julian) was buried. His illness recalls the fever which Alexander the Great contracted from bathing in the Cydnus. Nicephorus Phocas reconquered Tarsus and all Cilicia for the empire in A.D. 965. In the First Crusade Baldwin and Tancred captured Tarsus A.D. 1099, and there the two leaders had a serious quarrel. It formed part of the kingdom of Lesser Armenia for great part of the three centuries after A.D. 1180, and it was fortified by Leo II. and Hethoum I. But Turkoman and Egyptian invaders disputed its possession with the Greek emperors and Armenian kings and with one another. Finally it passed into Ottoman hands about the beginning of the 16th century.

Most of the successive masters of Tarsus had their own legends about its origin, usually with a religious character justifying and explaining their possession of the city. The Assyrian Sardanapalus, the native god Sandan, the Greek hero Perseus, the Greek god Heracles, are all called founder of Tarsus. Iapetus, *i.e.* Japhet, father of Javan "the Ionian," was called the grandfather of Cydnus, who gave name to the river. A curious ceremony was practised in honour of Sandan (identified with the Greek Heracles): a pyre was periodically erected and the god was burned on it. It is said that the original name of the city was Parthenia, which suggests that a virgin goddess was worshipped here as in so many shrines of Asia Minor and Syria: the virgin goddess Athena appears on Tarsian coins. The Baal of Tarsus is named in Aramaic letters on many of its coins in the Persian period.

The ruins of the ancient city are very extensive, but they are deeply buried, and make little or no appearance above the surface except in the Dunuk Tash (popularly identified as the "Tomb of Sardanapalus," a monument which, however, was at Anchiale, not at Tarsus). This shapeless mass of concrete was probably the substructure of a Graeco-Roman temple, from which the marble coating has been removed. The modern town has considerable bazaars and trade; but the climate is very oppressive, owing to the proximity of vast marshes which occupy the site of the harbour and the lower part of the original Cyndus course. The river was diverted from its former course by Justinian in the 6th century. The emperor's intention was only to carry off the surplus waters in time of flood and prevent inundations in the city, not to deprive Tarsus of what was its chief pride and boast; but gradually the neglect of subsequent centuries allowed the channel in the city to become blocked by accumulation of soil, and now the whole body of water flows in the new channel east of the city, except what is drawn off by an artificial irrigation course to water the gardens on the western side of the city. The population is about 25,000, including, besides Turks and Syrian Moslems, alsc Armenians, Greeks, Syrian Christians, Persians, Afghans, Ansaria (mostly gardeners) and even Hindus. There is a large American mission school called St Paul's Institute, giving a very comprehensive education to Armenians and Greeks drawn from an extensive district.

The literature regarding Tarsus is scanty, and few ancient inscriptions have been published. See W. B. Barker, *Lares and Penates*; G. F. Hill in the British Museum Catalogue of Coins; Six in *Numismatic Chronicle*, 1884, pp. 152 ff., 1894, pp. 329 ff.; E. Babelon in the Catalogue Bibl. Nat., "Perses Achéménides"; the numismatic works of B. V. Head, F. Imhoof Blumer, &c.; Waddington in *Bulletin de Corr. Hell.*, vii. pp. 282 ff.; Ramsay, *Cities of St Paul* (1907), pp. 85–245, and "Cilicia, Tarsus and the Great Taurus Pass" in *Geographical Journal* (1903), pp. 357–410; R. Heberdey and A. Wilhelm, "Reisen in Kilikien" (in the *Denkschriften d. kais. Akademie Wien*, 1896, xliv.), with works of other travellers, especially V. Langlois and Macdonald Kinneir. Callander in *Journal of Hellenic Studies*, 1904, pp. 58 ff., studied Dion Chrysostom's two *Tarsian Orations*. (W. M. RA.)

TART, a dish of baked pastry containing fruit, a fruit pie; also a small open piece of baked pastry with jam placed upon it. The word was adapted from the O.Fr. *tarte*; the older form must have been *torte*, as is seen in the mod. Fr. *tourte* and the diminutive *tortel* or *torteau*; the origin is the Lat. *torta*, twisted (*torquere*, to twist), used of a cake in Med. Lat., the paste or dough of cakes or tarts being rolled or twisted. The alteration of the vowel is also seen in Ital. *tartera*. In English there is some confusion with "tart," sharp, acid, bitter, which comes from O.E. *teart*, sharp, severe, properly "tearing," from *teran*, to tear; cf. "bitter," from "to bite."

TARTAGLIA, or TARTALEA, **NICCOLÒ** (*c.* 1506–1559), Italian mathematician, was born at Brescia. His childhood was passed in dire poverty. During the sack of Brescia in 1512, he was horribly mutilated by some French soldiers. From these injuries he slowly recovered, but he long continued to stammer in his speech, whence the nickname, adopted by himself, of "Tartaglia." Save for the barest rudiments of reading and writing, he tells us that he had no master; yet we find him at Verona in 1521 an esteemed teacher of mathematics. In 1534 he went to Venice. For Tartaglia's discovery of the solution of cubic equations, and his contests with Antonio Marie Floridas, see ALGEBRA (*History*). In 1548 Tartaglia accepted a situation as professor of Euclid at Brescia, but returned to Venice at the end of eighteen months. He died at Venice in 1559.

Tartaglia's first printed work, entitled *Nuova scienzia* (Venice, 1537), dealt with the theory and practice of gunnery. He found the elevation giving the greatest range to be 45°, but failed to demonstrate the correctness of his intuition. Indeed, he never shook off the erroneous ideas of his time regarding the paths of projectiles, further than to see that no part of them could be a straight line. He nevertheless inaugurated the scientific treatment of the subject. His *Quesiti et invenzioni diverse*, a collection of the author's replies to questions addressed to him by persons of the most varied conditions, was published in 1546, with a dedication to Henry VIII. of England. Problems in artillery occupy two out of nine books; the sixth treats of fortification; the ninth gives several examples of the solution of cubic equations. He published in 1551 *Regola generale per sollevare ogni affondata nave, intitolata la Travagliata Invenzione* (an allusion to his personal troubles at Brescia), setting forth a method for raising sunken ships, and describing the diving-bell, then little known in western Europe. He pursued the subject in *Ragionamenti sopra la Travagliata Invenzione* (May 1551). His largest work, *Trattato generale di numeri e misure*, is a comprehensive mathematical treatise, including arithmetic, geometry, mensuration, and algebra as far as quadratic equations (Venice, 1556, 1560). He published the first Italian translation of Euclid (1543), and the earliest version from the Greek of some of the principal works of Archimedes (1543). These included the tract *De insidentibus aquae*, of which his Latin now holds the place of the lost Greek text. Tartaglia claimed the invention of the gunner's quadrant.

Tartaglia's own account of his early life is contained in his *Quesiti*, lib. vi. p. 74. See also Buoncompagni, *Intorno ad un testamento inedito di N. Tartaglia* (Milan, 1881); Rossi, *Elogi di Bresciana illustri*, p. 386. Tartaglia's writings on gunnery were translated into English by Lucar in 1588, and into French by Rieffel in 1845.

TARTAN (from F. *tiretaine*, "linsie-wolsie," Sp. *tiritaña*, a kind of woollen cloth, perhaps so called from its thinness and lightness, cf. Sp. *tiritar*, to tremble with cold), a worsted cloth woven with alternate stripes or bands of coloured warp and weft, so as to form a chequered pattern in which the colours alternate in "sets" of definite width and sequence. The weaving of particoloured and striped cloth cannot be claimed as peculiar to any special race or country, for indeed such checks are the simplest ornamental form into which dyed yarns can be combined in the loom. But the term tartan is specially applied to the variegated cloth used for the principal portions of the distinctive costume of the Highlanders of Scotland. For this costume, and the tartan of which it is composed, great antiquity is claimed, and it is asserted that the numerous clans into which the Highland population were divided had each from time to time a special tartan by which it was distinguished. After the rebellion of 1745 various acts of parliament were passed for disarming the Scottish Highlanders and for prohibiting the use of the Highland dress in Scotland, under severe penalties. These acts remained nominally in force till 1782, when they were formally repealed, and since that time clan tartan has, with varying fluctuations of fashion, been a popular article of dress, by no means confined in its use to Scotland alone; and many new and imaginary "sets" have been invented by manufacturers, with the result of introducing confusion in the heraldry of tartans, and of throwing doubt on the reality of the distinctive "sets" which at one time undoubtedly were more or less recognized as the badge of various clans.

Undoubtedly the term tartan was known, and the material was woven, "of one or two colours for the poor and more varied for the rich," as early as the middle of the 15th century. In the accounts of John, bishop of Glasgow, treasurer to King James III., in 1471, there occurs, with other mention of the material, the following:—"Ane elne and ane halve of blue Tartane to lyne his gowne of cloth of Gold." It is here obvious that the term is not restricted to particoloured chequered textures. In 1538 accounts were incurred for a Highland dress for King James V. on the occasion of a hunting excursion in the Highlands, in which there are charges for "variant cullorit velvet," for "ane schort Heland coit," and for "Heland tartane to be hose to the kinge's grace." Bishop John Lesley, in his *De origine, moribus, et rebus gestis Scotorum*, published in 1578, says of the ancient and still-used dress of the Highlanders and Islanders, "all, both noble and common people, wore mantles of one sort (except that the nobles preferred those of several colours)." George Buchanan, in his *Rerum Scoticarum historia* (1582), as translated by Monypenny (1612), says of the Highlanders, "They delight in marled clothes, specially that have any long stripes of sundry colours; they love chiefly purple and blue. Their predecessors used short mantles or plaids of divers colours sundry ways divided; and amongst some the same custom is observed to this day." A hint of clan tartan distinctions is given by Martin Martin in his *Western Isles of Scotland* (1703), which work also contains a minute description of the dress of the Highlanders and the manufacture of tartan. "Every isle," he observes, "differs from each other in their fancy of making plaids, as to the stripes in breadth and colours. This humour is as different through the mainland of the Highlands, in so far that they who have seen those places are able at the first view of a man's plaid to guess the place of his residence."

The following lines give a brief description of the colours of the tartans of the principal clans. The kilt-tartan colour is given in each case; the plaid-tartans vary in slight particulars.

Campbell of Breadalbane, light green, crossed with darker green, the stripes broad with narrow edging of yellow. *Campbell of Argyll*, light green crossed with dark green, narrow independent cross lines of white. *Cameron*, brick-red with broad chequered cross of same colour, edged white and with broad centre of ground colour, two independent cross lines of green. *Forbes*, yellow green, crossed with broad dark-green lines, centred black, independent cross lines yellow. *Fraser*, red ground, main cross lines red with deeper red centre edged with blue, independent cross lines blue. *Gordon*, dark blue-green ground, with broad cross lines of lighter green, narrow centre line yellow. *Graeme*, light green ground, crossed with darker green in small chequer, independent cross lines dark green. *Grant*, scarlet, with broad black-edged scarlet crossings, black independent cross lines. *Macdonald of Glengarry and Keppoch*, red, with open broad blue cross lines, and two independent blue crossings. *Macdonald of Glencoe*, green with broad dark-green crossing, the whole covered with fine red lines. *Macdonald of Clanranald*, light green with broad dark-green crossing, covered with fine red lines. *Macgregor*, scarlet, with narrow scarlet cross lines, edged and centred blue, widely spaced. *Mackintosh*, red with blue-edged and centred crossings of red, and independent blue cross lines. *Mackenzie*, blue-green, broad crossing of same colour with darker edges, independent cross lines, alternately red and white, over the main crossings. *Macleod*, green, with dark-green crossings, over crossings, every other square, a red line. *Macpherson*, pale grey, four darker grey bars at crossings, the whole covered with red double independent lines. *Munro*, red with broad green stripe and narrow lines forming a check of black and yellow. *Murray*, green, close crossings of darker green, independent lines red. *Stewart*, scarlet, deep coloured crossings with scarlet centre, fine widely spaced dark independent lines.

See W. and A. Smith, *Tartans of the Clans of Scotland* (1850); J. Sobieski Stuart, *Vestiarium Scoticum* (1842); R. R. M'Ian, *Clans of the Scottish Highlands* (1845–46); J. Grant, *Tartans of the Clans of Scotland* (Edinburgh, 1885).

TARTAR, the name commonly applied to crude acid potassium tartrate or "bitartrate of potash." $HK(C_4H_4O_6)$. During the process of fermentation wines deposit a crystalline crust of argol; this, after being roughly purified by recrystallization, is known as tartar, and when further purified and freed from colouring matters becomes "cream of tartar," also called technically "cream." With the iatrochemists tartar was a generic term which included both this *tartarus vini* and various substances obtained from it, and even salts, such as salt of sorrel (potassium oxalate), that resembled it. Thus *sal fixum tartari* was potassium carbonate, which on exposure to the air deliquesces to *oleum tartari per deliquium*; neutral potassium tartrate was called *tartarus tartarisatus*, because it was prepared by neutralizing ordinary tartar with the sal fixum; *tartarus chalybeatus* was a preparation with iron; and *spiritus tartari*, used by Paracelsus, was prepared by dry distillation of tartar. Paracelsus also used the term in a still wider sense to signify abnormal precipitates or sediments deposited from animal secretions; the same idea is apparent in the popular application of the word to the salivary calculus which forms on the teeth.

Cream of tartar is prepared by dissolving granulated argol in boiling water and allowing the solution to stand. The clear liquid is then drawn off and crystallized. The slightly coloured crystals thus obtained are redissolved in hot water, the colouring matters got rid of by means of pipeclay or egg-albumen, and the solution filtered and crystallized, the name "crean of tartar" being originally applied to the crust of minute crystals that form on its surface as it cools. The salt crystallizes in masses of small, hard, colourless, transparent, rhombic prisms. It is precipitated when an excess of a potassium salt is added to a solution of tartaric acid, but it dissolves in mineral acids, and in alkalis and alkaline carbonates. Solutions of boric acid or borax dissolve it freely, forming soluble cream of tartar, which is a white powder permanent in the air when made with the acid, but deliquescent when borax is employed. Its slight solubility in alcohol explains why it is deposited by wines as they mature. One part by weight of the salt dissolves in 15 parts of boiling water, but at lower temperatures the solubility is greatly diminished, and at 0° C. about 416 parts of water are required. When heated it is decomposed with formation of potassium carbonate and carbon, inflammable gases having an odour of burnt bread being evolved. The salt is used for the manufacture of tartaric acid; it is also employed in the mordant bath for wool-dyeing, with powdered chalk and alum for cleaning silver, and for the preparation of effervescing drinks and baking-powder. In medicine as *potassii tartras acidus* it is of some slight importance as a diuretic and purgative. The more soluble normal salt, $K_2(C_4H_4O_6)$, is used for the same purposes; it is formed by dissolving powdered cream of tartar in a hot solution of potassium carbonate. If sodium carbonate is substituted the result is $KNa(C_4H_4O_6)$, or Rochelle salt.

Tartar emetic (potassium antimonyl tartrate) $K\cdot(SbO)C_4H_4O_6\cdot\frac{1}{2}H_2O$. This substance has been known for a long period, being mentioned by Basil Valentine. It may be prepared by warming 3 parts of antimonious oxide with 4 parts of cream of tartar, in the presence of water, replacing the water as it evaporates; after digestion is complete, the solution is filtered hot. Powder of algaroth (*q.v.*) may be used in place of the antimony oxide. Tartar emetic crystallizes in small octahedra, which lose their water of crystallization gradually on exposure to air, and become opaque. It is soluble in 14·5 parts of cold water and 1·9 parts of hot, the solution showing an acid reaction to litmus. It possesses a nauseous metallic taste and produces vomiting when taken internally, whilst in large doses it is poisonous. It is used medicinally, and also as a mordant in dyeing and calico-printing.

TARTARIC ACID (dihydroxy-succinic acid), $C_4H_6O_6$, or $HO_2C\cdot CH(OH)\cdot CH(OH)\cdot CO_2H$. Four acids of this composition are known, namely dextro- and laevo-tartaric acids, racemic acid and mesotartaric acid, the two last being optically inactive (see STEREO-ISOMERISM). Their constitution follows from their formation from dibromosuccinic acid and from their synthesis from glyoxal cyanhydrin, these two methods producing the inactive racemic form which may then be split into the active components. Dextro-tartaric acid occurs in the free state or as the potassium or calcium salt in grape juice and in various unripe fruits. During the alcoholic fermentation of grape juice it is deposited in the form of an impure acid potassium tartrate which is known as argól, and when purified as cream of tartar. For the preparation of the acid the crude argol is boiled with hydrochloric acid and afterwards precipitated as calcium tartrate by boiling with milk of lime, the calcium salt being afterwards decomposed by sulphuric acid. It may also be obtained (together with racemic acid) by oxidizing milk sugar, saccharic acid, &c., with nitric acid, and by the reduction of oxalic ester with sodium amalgam (H. Debus, *Ann.*, 1873, 166, p. 109). It crystallizes from water in large prisms which melt at 168–170° C., and on further heating gives an anhydride and finally chars, emitting a characteristic odour and forming pyroracemic and pyrotartaric acids. It behaves as a reducing agent. Chromic acid and potassium permanganate oxidize it to formic and carbonic acids, whilst hydrogen peroxide in the presence of ferrous salts gives dihydroxymaleic acid (H. J. H. Fenton, *Jour. Chem. Soc.*, 1894, p. 899; 1895, pp. 48, 774; 1896, p. 546). Hydriodic acid and phosphorus reduce it to malic acid and finally to succinic acid. Calcium chloride gives a white precipitate of calcium tartrate in neutral solutions, the precipitate being soluble in cold solutions of caustic potash but re-precipitated on boiling. It prevents the precipitation of many metallic hydroxides by caustic alkalis. It carbonizes when heated with strong sulphuric acid, giving, among other products, carbon monoxide and carbon dioxide. A small crystal of oxalic acid added to concentrated sulphuric acid containing about 1 per cent. of resorcin gives a characteristic violet red coloration.

Laevo-tartaric acid is identical in its chemical and in most of its physical properties with the dextro-acid, differing chiefly in its action on polarized light, the plane of polarization being rotated to the left. By mixing equal quantities of the two forms in aqueous solution heat is evolved and racemic acid, $(C_4H_6O_6)_2\cdot 2H_2O$, is obtained. This variety is also formed by the hydrolysis of glyoxal cyanhydrin (F. Pollak, *Monats.*, 1894, 15, p. 469); by heating a solution of desoxalic acid; by the oxidation of fumaric acid with potassium permanganate; by the action of silver oxide on dibromosuccinic acid, and by the oxidation of mannite, dulcite, inulin, &c., with nitric acid. In the anhydrous state it melts at 205–206° C. Mesotartaric acid is formed when cinchonine tartrate is heated for some time at 170° C. (L. Pasteur, *Ann.*, 1853, 88, p. 212); by heating tartaric or racemic acid for some time with water to 165° C.; by the oxidation of laevulose; and by the oxidation of phenol or maleic acid with an alkaline solution of potassium permanganate (O. Doebner, *Ber.*, 1891, 24, p. 1755; A. Kekulé and R. Anschutz, *ibid.*, 1881, 14, p. 714). It crystallizes in prisms, and in the anhydrous state melts at 140° C. On prolonged boiling with aqueous hydrochloric acid it yields racemic acid. The sodium ammonium salt is not capable of decomposition into its optical antipodes, as is sodium ammonium racemate.

Tartaric acid as used in medicine is derived from potassium acid tartrate. Its impurities are lead, oxalic acid, lime and potassium tartrate. It is incompatible with potassium, calcium, mercury and vegetable astringents. Tartaric acid is rarely used alone, but is contained in *pilula quininae sulphatis* and in Seidlitz powder (see SODIUM), and is a constituent of many proprietary granular effervescent preparations. If taken in overdose or in a concentrated form tartaric acid produces severe gastro-enteritis. In these cases lime-water, alkalis and magnesia should be used as antidotes, and opium may be required.

TARTARUS, in Greek mythology, the son of Aether and Gaea, father of Typhoeus and the giants. In the *Iliad* the word denotes an underground prison, as far below Hades as earth is below heaven, in which those who rebelled against the will of Zeus were confined. In later writers Tartarus is the place of punishment of the wicked after death, and is used for the underworld generally. Cf. ABYSS.

TARTINI, GIUSEPPE (1692–1770), Italian violinist, composer and musical theorist, was born at Tirano in Istria on the 12th of April 1692. In early life he studied, with equal want of success, for the church, the law courts, and the profession of arms. As a young man he was wild and irregular, and he crowned his improprieties by clandestinely marrying the niece of Cardinal Cornaro, archbishop of Padua. The cardinal resented the marriage as a disgraceful mésalliance, and denounced it so violently that the unhappy bridegroom, thinking his life in danger, fled for safety to a monastery at Assisi, where his character underwent a complete change. He studied the theory of music under Padre Boemo, the organist of the monastery, and, without any assistance whatever, taught himself to play the violin in so masterly a style that his performances in the church became the wonder of the neighbourhood. For more than two years his identity remained undiscovered, but one day the wind blew aside a curtain behind which he was playing, and one of his hearers recognized him and betrayed his retreat to the cardinal, who, hearing of his changed character, readmitted him to favour and restored him to his wife.

Tartini next removed to Venice, where the fine violin-playing of Veracini excited his admiration and prompted him to repair, by the aid of good instruction, the shortcomings of his own self-taught method. He left his wife with relations and returned to Ancona, where he studied for a time. In 1721 he returned to Padua, where he was appointed solo violinist at the church of San Antonio. From 1723 to 1725 he acted as conductor of Count Kinsky's private band in Prague. In 1728 he founded a school for violin in Padua. The date of his presence in Rome does not seem to be clearly established, but he was in Bologna in 1739. Afterwards he returned to his old post in Padua, where he died on the 16th of February 1770.

Tartini's compositions are very numerous, and faithfully illustrate his passionate and masterly style of execution, which surpassed in brilliancy and refined taste that of all his contemporaries. He frequently headed his pieces with an explanatory poetical motto, such as "Ombra cara," or "Volgete il riso in pianto o mie pupille." Concerning that known as *Il Trillo del Diavolo*, or *The Devil's Sonata*, he told a curious story to Lalande, in 1766. He dreamed that the devil had become his slave, and that he one day asked him if he could play the violin. The devil replied that he believed he could pick out a tune, and thereupon he played a sonata so exquisite that Tartini thought he had never heard any music to equal it. On awaking he tried to note down the composition, but succeeded very imperfectly, though the *Devil's Sonata* is one of his best productions.

Tartini is historically important as having contributed to the science of acoustics as well as to musical art by his discovery (independently of Sorge, 1740, to whom the primary credit is now given) of what are still called "Tartini's tones" (see SOUND and HEARING), or differential tones.

The phenomenon is this:—when any two notes are produced steadily and with great intensity, a third note is heard, whose vibration number is the difference of those of the two primary notes. It follows from this that any two consecutive members of a harmonic series have the fundamental of that series for their difference tone —thus, $\frac{E}{C}$, the fourth and fifth harmonic, produce C, the prime or generator, at the interval of two octaves under the lower of those two notes; $\frac{E}{G}$, the third and fifth harmonic, produce C, the second harmonic, at the interval of a 5th under the lower of those two notes. The discoverer was wont to tell his pupils that their double-stopping was not in tune unless they could hear the third note; and Henry Blagrove (1811–1872) gave the same admonition. The phenomenon has other than technical significance; an experiment by Sir F. A. G. Ouseley showed that two pipes, tuned by measurement to so acute a pitch as to render the notes of both inaudible by human ears, when blown together produce the difference of tone of the inaudible primaries, and this verifies the fact of the infinite upward range of sound which transcends the perceptive power of human organs. The obverse of this fact is that of any sound being deepened by an 8th if the length of the string or pipe which produces it be doubled. The law is without exception throughout the compass in which our ears can distinguish pitch, and so, of necessity, a string of twice the length of that whose vibrations induce the deepest perceivable sound must stir the air at such a rate as to cause a tone at an 8th below that lowest audible note. It is hence manifest that, however limited our sense of the range of musical sound, this range extends upward and downward to infinity. Tartini made his observations the basis of a theoretical system which he set forth in his *Trattato di Musica, secondo la vera scienzia dell'Armonia* (Padua, 1754) and *Dei Principij dell' Armonia Musicale* (Padua, 1767). He also wrote a *Trattato delle Appogiature*, posthumously printed in French, and an unpublished work, *Delle Ragioni e delle Proporzioni*, the MS. of which has been lost.

TAS-DE-CHARGE, a French term in architecture, for which there is no equivalent in English, given to the lower courses of a Gothic vault, which are laid in horizontal courses and bonded into the wall, forming a solid mass; they generally rise about one-third of the height of the vault, and as they project forwards they lessen the span to be vaulted over.

TASHKENT, or TASHKEND, one of the largest and most important cities of Russian Central Asia, and capital of Russian Turkestan, situated in the valley of the Chirchik, some 50 m. above its confluence with the Syr-darya, in 40° 20′ N., 69° 18′ E. It is connected by rail with Krasnovodsk (1085 m.) on the Caspian, and since 1905 with Orenburg (1150 m.). The city, formerly enclosed by walls (now ruinous), is surrounded by luxuriant gardens, and its houses are buried among the fruit and other trees which grow alongside of the irrigation canals. The buildings, which are of stone and sun-dried bricks, are mostly low, on account of the earthquakes which frequently disturb the region. The native city in 1871 had 78,130 inhabitants, and in 1897 156,414, mostly Sarts, with Uzbegs, Kirghiz, Jews, Russians and Germans. The Russian city, to the south-east, dating from 1865, has clean, broad streets lined with poplars, and canals, the low, pleasant-looking houses being surrounded by gardens. In 1875 its population, exclusive of the military, was 4860, mostly Russians, and in 1900 about 25,000. Tashkent has a public library containing a valuable collection of works on Central Asia, an astronomical observatory and a museum.

TASHKURGHAN, or KHULM, a khanate and town of Afghan Turkestan. The khanate lies between Kunduz and Balkh. The ancient town of Khulm stood in the Oxus plain, surrounded by orchards of famous productiveness; but it was destroyed by Ahmad Shah Abdali, who founded Tashkurghan in the middle of the 18th century, and took all the inhabitants away from Khulm to populate it. Ancient Khulm is now only a mass of ruins; but Tashkurghan, lying two or three miles to the south of it, has become the great trade-mart of Afghan Turkestan and second only in importance to Mazar-i-Sharif, the military centre of the province; while it is much larger and more prosperous than the latter place. At Tashkurghan the caravans from India and Bokhara meet, and from here the merchandise is distributed all over the country. A hill fortress dominates the town and overlooks the debouchment of the road from Haibak and Kabul into the plains of the Oxus.

TASMAN, ABEL JANSZOON (*c.* 1603–1659), the greatest of Dutch navigators, the discoverer of Tasmania, New Zealand, the Tonga and the Fiji Islands, and the first circumnavigator of Australia, was born at Lutjegast in Groningen, about 1603. In 1634 we first meet with him in the East Indies, sailing from Batavia (Feb. 18) to Amboyna. On the 30th of December 1636 he sailed from Batavia for home; reached Holland August 1, 1637; started on his return to the East April 15, 1638; and reappeared at Batavia October 11, 1638. On the 2nd of June 1639 Tasman, along with Matthew (Matthijs Hendricxsen) Quast, was despatched by Antony Van Diemen, governor-general of the Dutch East Indies (1636–45), on a voyage to the north-western Pacific, in quest of certain "islands of gold and silver," supposed to lie in the ocean east of Japan. On this voyage Tasman and Quast visited the Philippines and improved Dutch knowledge of the east coast of Luzon; they also discovered and mapped various islands to the north, apparently the Bonin archipelago. Sailing on to N. and E. in search of the isles of precious metals, they ranged about fruitlessly in the northern Pacific, at one time believing themselves to be 600 Dutch miles east of Japan. After this the voyage was continued almost constantly westward, but in varying latitudes, reaching as high as 42° N., always without success. On the 15th of October the navigators decided to return, and, after touching at Japan, anchored at the Dutch fortress-station of Zeelandia in Formosa on the 24th of November 1639. After this Tasman was engaged in operations in the Indian seas (sailing to Formosa, Japan, Cambodia, Palembang, &c., as a merchant captain in the service of the Dutch East India Company) until 1642, when he set out on his first great "South Land" expedition. This was planned and organized by Governor Van Diemen, who cherished great schemes for the extension of the Dutch colonial empire. Several Dutch navigators had already discovered various portions of the north and west coasts of Australia (as in 1605–06, 1616, 1618–19, 1622, 1627–28, &c.), but Tasman now first showed that this great South Land did not stretch away to the southern pole, but was entirely encircled by sea within comparatively moderate limits. Sailing from Batavia on the 14th of August 1642 with two vessels, the "Heemskerk" and "Zeehaen," and calling at Mauritius (September 5 to October 8), Tasman sailed first S., then E., almost seven weeks, and on the 24th of November sighted (in 42° 25′ S., as he made it) the land which he named *Anthoonij van Diemen's landt* after Van Diemen, now called Tasmania. He doubled the land, which he evidently did not perceive was an island, coasting its southern shores, and, running up Storm Bay, anchored on the 1st of December in Frederick Henry's Bay, on the east coast of Tasmania (in 43° 10′ S., according to his reckoning)—so named after Prince Frederick Henry of Nassau, then the head of the Dutch republic. There he set up a post on which he hoisted the Dutch flag. Quitting Van Diemen's Land on the 5th of December, Tasman steered E. for the Solomon Islands, and on the 13th of December discovered (in 42° 10′ S., as he reckoned) a "high mountainous country," which he called *Staten landt* ("Land of the States," *i.e.*, of Holland, now New Zealand). Tasman and his company believed the newly discovered land to form part of the same great antarctic continent as the other *Staten landt* which Schouten and Lemaire had sighted and named to the east of Tierra del Fuego. Cruising up N.E. along the west coast of the South Island, he anchored on the 18th of December in 40° 50′ S., at the entrance of a "wide opening," which he took to be a "fine bay" (Cook's Strait). He gave the name of *Moordenaars* (*Murderers*, now softened to *Massacre*) *Bay* to this spot, where several of his men were killed by the natives (December 19). From Murderers' Bay Tasman sailed S.E. along the south shore of Cook's Strait, apparently getting into Blind or Tasman Bay, but not discovering the full extent of the strait here dividing New Zealand into two main islands. Returning westward he then coasted the west side of the North Island, till, on the 4th of January 1643, he came to the northern extremity of New Zealand, in 34° 35′ S. (in his reckoning). Thence he bore away to N.N.E., at first intending to keep that course for 30° of longitude from North Cape, New Zealand. On the 19th to 25th of January, in 22° 35′, 21° 20′, and 20° 15′ S. (Tasman's reckonings), he discovered various islands of the Tonga or Friendly group, especially Amsterdam (Tongatabu), Middelburg (Eva), and Rotterdam. Here the ships took in water and provisions, which they had not done since leaving Mauritius, and the crews went on shore for the first time since leaving Van Diemen's Land. Rotterdam Island they explored with some care. Thence Tasman steered N. and W., reaching on the 6th of February the eastern part of the Fiji archipelago (in 17° 29′ S., by his reckoning), which he called Prince William's Islands and Heemskerk's Shoals; on the 22nd of March he sighted the islands of Ontong Java (in 5° 2′ S., according to Tasman, and in 159° 30′ E., Greenwich). On the 1st of April he was near the north-eastern extremity of New Ireland (Neu Mecklenburg), mistaken by him for a part of New Guinea, in 40° 30′ S., off a point known to the Spaniards as *Cabo S. Maria.* Thence he passed westward along the north of New Ireland, New Hanover, New Britain (Neu Pommern) and New Guinea. He reached the western extremity of New Guinea on the 18th of May; Schouten's Islands were noted to the south of the vessels' course on the 12th of May. Tasman's track, lying between New Guinea and Halmahera (Gilolo), then brought him south to Ceram; he passed through the narrow strait between Celebes and Buton on the 27th of May, and arrived at Batavia on the 15th of June 1643 after a ten months' voyage. The materials for an account of Tasman's important second voyage in 1644 are scanty, but we know he was instructed to obtain a thorough knowledge of Staten Land and Van Diemen's Land, and to find out "whether New Guinea is a continent with the great Zuidland, or separated by channels and islands," and also "whether the new Van Diemen's Land is the same continent with these two great countries or with one of them." In this voyage Tasman had three ships under his command, the "Limmen," "Zeemeeuw" (or "Meeuw"), and "Brak" (or "Bracq"). His course lay along the south-west coast of New Guinea; he mistook the western opening of Torres Straits for a bay, but explored (and perhaps named) the Gulf of Carpentaria: for the first time the coast-line of this great bay was mapped with fair accuracy. Though preceded by Jansz (1606) and Carstensz (1623) on the east shore of the gulf as far as 17° S., Tasman first made known the south, and most of the west, coast. Beyond this he explored the north and west coasts of Australia as far as 22° S., and established the absolute continuity of all this shore-line of the "Great Known South Continent"; his chart gives soundings for the whole of this coast. Tasman's achievements were coldly received by the Dutch colonial authorities; but on the 4th of October 1644 they rewarded him with the rank of commander (he had frequently enjoyed the use of the title already). On the 2nd of November 1644 he was also made a member of the Council of Justice of Batavia. He was a member of the committee appointed on the 18th of April 1645 to declare a truce between the Dutch East India Company and the viceroy of Portuguese India. In 1647 he commanded a trading fleet to Siam, and in 1648 a war-fleet sent against the Spaniards of the Philippines (May 15, 1648, to January 1649). By 1653 he had quitted the company's service, but still lived, apparently as one of its wealthiest citizens, in and near Batavia. His will, made the 10th of April 1657, seems to have but slightly preceded his death, which probably happened before October 22, 1659, and certainly before February 5, 1661.

See Siebold's paper in *Le Moniteur des Indes-Orientales et Occidentales*, 1848–49, pt. i. p. 390; the paper on Tasman by C. M. Dozy in *Bijdragen tot de Taal-, Land-, en Volkenkunde van Nederlandsch-Indie*, 5th series, vol. ii. p. 308; R. H. Major, *Early Voyages to . . . Australia* (London, Hakluyt Society, 1859), especially pp. xciii.–ciii., 43–58 (here are printed the instructions for Tasman and his colleagues on the voyage of 1644); G. Collingridge, *Discovery of Australia* (Sydney, 1895), especially pp. 238–40, 279–80; and, above all, J. E. Heeres and others, *Tasman's Journal . . . facsimiles of the original MS. . . . . with . . . life . . . . of . . . . Tasman*, &c. (Amsterdam, 1898)—here the *Life of Tasman*, with its appendices, is separately paged (163 pp.). See also *Aandeel der Nederlanders in de Ontdekking van Australië*, 1606–1765 (in Dutch and English, Leiden and London, 1899), especially pp. vi., viii., xii.–xv., 72; the valuable summary of the voyage of 1642–43 in the anonymous *Account of several late Voyages and Discoveries* (beginning with Sir John Narborough's), London, 1711, with subtitle, *Relation of a Voyage . . . of Captain Abel Jansen Tasman* (originally extracted from his journals by Dirk Rembrantse in Dutch, published in English in Dr Hook's collections); also *The Discovery of Van Diemen's Land in 1642*, by James Backhouse Walker (Hobart, 1891). A draft journal of the voyage of 1642–43, probably made by a sailor on the expedition, is in the state archives at The Hague. There are also several copies made from Tasman's official journal; the best of these (the original fair copy) is reproduced in Heeres' *Tasman's Journal*, 1898, noticed above.

An original chart of Tasman's, made after the voyage of 1644, has been discovered and is in the possession of Prince Roland Bonaparte. Before this discovery reliance was placed on an excellent copy, probably made about 1687, by Captain Thomas Bowrey (art. 12 in the miscell. MS. collection marked 5222 in the British Museum, London). This gives the tracks of both the voyages 1642–43 and 1644, and the soundings of the latter. Burgomaster Witsen, of *Noord en Oost Tartarye* fame (1705), preserved a brief record of certain observations made in Tasman's voyage of 1644, between 13° 8′ and 19° 35′ S. (and approximately between 129° 30′ and 120° E., Greenwich). This was translated by A. Dalrymple in his *Papua* (reprinted in R. H. Major, *Early Voyages to . . . Australia*, xcviii.–xcix.). Basil Thomson, *Diversions of a Prime Minister* (Edinburgh, 1894), p. 311, &c., records that the remembrance of Tasman's visit to the Tonga Islands still remains "fresh to the smallest details" among the natives. (C. R. B.)

TASMANIA, a British colonial state, forming part of the Australian Commonwealth. It is composed of the island of Tasmania and its adjoining islands, and is separated from the Australian continent on the south-east by Bass Strait. The

island of Tasmania is triangular in shape, area 24,331 sq. m. (with the other islands 26,215 sq. m.), 200 m. from N. to S., and 245 m. from E. to W.

Coastal Features.—The southern portion of the eastern shore of Tasmania is remarkable for its picturesque inlets and bold headlands. The principal inlet is Storm Bay, which has three well-defined arms. The most easterly is Norfolk Bay, enclosed between Forestier's Peninsula and Tasman Peninsula. The middle arm is Frederick Henry Bay, and the western the estuary of the Derwent. It is on this estuary that Hobart, the capital of the island, is situated. Besides the main entrance to Storm Bay, between Cape Raoul and Tasman Head, there is D'Entrecasteaux Channel, which divides North and South Bruni Island from the mainland. This channel has two branches, the easterly forming the entrance into Storm Bay, and the western being the estuary of the Huon river. On the east coast lies the peculiarly-shaped Maria Island, almost severed by deep indentations on the east and west. Above this island is Oyster Bay, formed by the projection, Freycinet Peninsula. On the south are some very prominent headlands. In the south-west lies the fine harbour of Port Davey, which receives several small rivers. Proceeding northward along the west coast the most conspicuous headlands are Rocky Point, Point Hibbs and Cape Sorell, which stands at the entrance of Macquarie Harbour, the deep inlet receiving the waters of the river Gordon and several smaller streams. North of this there are several prominent headlands. The west coast terminates at Cape Grim, opposite which are the group known by the name of Hunter's Islands. Going eastward along the north coast Circular Head is met with, a narrow peninsula running out for six miles and terminating in a rocky bluff 400 ft. high. Further east are Emu Bay, Port Frederick, Port Sorell and Port Dalrymple, into which flows the Tamar river, on which Launceston is situated. In Bass Strait are several large islands belonging to Tasmania; King's, Flinders, Cape Barren and Clarke Islands are the largest. Flinders Island has an area of 513,000 acres. Among the rivers flowing northward to Bass Strait are the Tamar, Inglis, Cam, Emu, Blyth, Forth, Don, Mersey, Piper and Ringarooma. The Macquarie, receiving the Elizabeth and Lake, falls into the South Esk, which unites with the North Esk to form the Tamar at Launceston. Westward, falling into the ocean, are the Hellyer, Arthur and Pieman. The King and Gordon gain Macquarie Harbour; the Davey and Spring, Port Davey. The central and southern districts are drained by the Derwent from Lake St Clair—its tributaries being the Nive, Dee, Clyde, Ouse and Jordan. The Huon falls into D'Entrecasteaux Channel. The main axis of the Great Cordillera—so termed originally by Sir Roderick Murchison—bordering the eastern coast-line of Australia, may be traced across Bass Strait in the chain of islands forming the Furneaux and Kent group, which almost continually link Tasmania with Wilson's Promontory, the nearest and most southerly part of the Australian mainland. Tasmania is wholly occupied by the ramifications of this chain, and in itself may be said to embrace one and all of its characteristic features.

Taking a stand near Lake Fergus, to the east of Lake St Clair, the observer will find himself nearly in the centre of an extensive plateau, with an elevation, especially on the northern side, of between three and five thousand feet above the sea-level. This elevated plateau extends from Dry's Bluff in the north to the Denison Range in the south-west, and although often receding at points adjacent to the sources of the principal rivers, invariably presents a bold crested front to the north, west and east. At its greatest elevation it is comparatively level, and contains many extensive freshwater basins, such as Lake Augusta, Lake St Clair, Lake Sorell, Lake Echo, Lake Crescent, Arthur's Lake and the Great Lake. The marginal crests of this mountain tableland, together with its upper surface, are known locally as "Tiers," and have a very commanding aspect in the neighbourhood of Longford, Westbury, Deloraine and Chudleigh. The extent of the principal elevated plateau is best appreciated when we consider that it maintains its general altitude in a westerly direction from Dry's Bluff (4257 feet) on the north to Cradle Mountain (5069 feet) in the north-west, a distance of nearly 50 miles; from Dry's Bluff in a south-westerly direction to Denison Range, a distance of over 60 miles; and from Dry's Bluff to Table Mountain in a southerly direction, a distance of above 43 miles. This plateau itself again rests upon a more extended tableland, stretching westwards, and, with the Middlesex Plains, the Hampshire Hills and the Emu Plains, maintaining an altitude of 1200 to 2000 feet. Its limits follow the coast-line more or less closely, the space between it and the sea often broadening out into low-lying tracts not much raised above the sea-level. Here and there, rising abruptly from its surface, are to be seen isolated peaks, the most characteristic of which are Valentine's Peak (3637 feet) and Mount Pearse. Ridges and plateaus of a similar character, but more or less isolated, such as Ben Lomond (5010 feet) and Mount Wellington (4166 feet), are to be found in the north-east and south-west of the island. Towards the extreme west and south, anticlinal and synclinal ridges trend north and south, the most characteristic being the Huxley, Owen, Sedgwick, Franklin and Arthur Ranges. Settlement of population has taken place principally among the plains and lower levels of the north-western, midland and south-eastern parts of the island, following in the main the rocks of Tertiary and Mesozoic age. In the Recent Tertiary period the soils of these plains and valleys have been greatly enriched by extensive outbursts of basalt with accompanying tuffs. These basalts produce a very rich chocolate soil, and were it not for their influence, the greater part of what is now the most fertile part of the island would have been comparatively poor or altogether sterile.

The appearance of the island throughout is wonderfully beautiful, with its open plains, bordered by far-extending precipitous mountain tiers, its isolated shaggy peaks and wooded ranges, and its many noble rivers and lakes. Its coasts for the most part, especially towards the south, are bold, and frequently indented with splendid bays and harbours, affording ample shelter and safe anchorage for ships. On the western side one is reminded of scenes in the highlands of Ross-shire and Inverness-shire in Scotland, from the picturesque character of the blue, white, and pinkish crystalline peaks and the fantastic outlines of the mountain ranges which rise abruptly to a height of from 2000 to nearly 3000 feet above the Button Grass Plains. (T. A. C.)

Geology.—Tasmania is, geologically, an outlier of the Australian continent. It is most intimately connected with Victoria, from which it was only separated by the foundering of Bass's Strait in late Pliocene or early Pleistocene times. The precise date of the separation is fixed as later than the Miocene, since the fringe of the marine Miocene deposits along the southern coast of Victoria is broken, from Flinders to Alberton; and this gap was no doubt due to the subsidence of the land, of which the islands in the Bass Strait are remnants, which then connected Tasmania with the continent. The latest date for the existence of this connexion is given by the absence from Tasmania of the dingo, the lyre-bird and the giant marsupials; so that the isolation of Tasmania was earlier than the arrival of those animals in south-eastern Australia. That it was not much earlier is shown by the fact that some still living species of mammals, such as the thylacine, existed before the separation.

The geological sequence in Tasmania is full, and the island contains a better series of Carboniferous rocks than is found in Victoria. The nucleus of the island is a block of Archean rocks, which are not, so far as is known, extensively exposed. The most certain representatives of the Archean are the gneiss and schists of the Dove river and the upper Forth, and the hornblende-schists, which are exposed in the river valleys on the margins of the central plateau. The Mount Lyell schists which underlie the West Coast Range, and the quartzites of Port Davey on the western coast, have also been regarded as Archean. The Lower Palaeozoic systems begin with the Cambrian, which are found in northern Tasmania near Latrobe, and contain Cambrian fossils as *Dikelocephalus Tasmanicus* and *Conocephalites stephensi*. The Ordovician system has not been certainly identified; but probably many of the slates and quartzites in north-western Tasmania and of the mining field of Beaconsfield on the estuary of the Tamar, are Ordovician. The Silurian system, however, is well developed in north-western Tasmania, and is represented by slates, limestones and sandstones yielding a distinctively Silurian fauna. The rocks are best known by the limestones in the lead mining field at Zeehan, and the slates, including the tin mine of Mount Bischoff.

The Devonian system is best represented by the massive conglomerates and quartzites, which form the West Coast Range extending from Mount Lyell on Macquarie Harbour, through Mounts Jukes, Owen, Lyell, Murchison and Geikie, to Mount Black. These mountains consist of detached remnants of a sheet of quartz conglomerates, interbedded with sandstones, containing crinoid stems and obscure brachiopods. They rest unconformably on the Silurian rocks on the King river and to the west are faulted against the schists by a powerful overthrust fault, traversing the Mount Lyell copper field. A northern extension of these conglomerates forms the Dial Range near Burnie. The Devonian period, as in Victoria, was marked by a series of granitic intrusions, which altered the older beds on the contact, while the quartz-porphyry dikes, which are intrusive in the Silurian rocks at the Mount Bischoff tin mine, doubtless belong to this period. The Carboniferous system begins with a series of marine limestones, shales and grits, including a rich Lower Carboniferous fauna. The Carboniferous rocks occupy the whole of the south-eastern corner of Tasmania; and one outlier occurs on the northern coast in the Mersey Valley. This formation helps to build up the central plateau, and a band outcrops around its edge. The Upper Carboniferous includes beds of shale and coal; but though the coal is good, the seams are thin and have not been much worked. The Coal Measures are covered by marine shales with numerous bryozoa; and, on the horizon of the Greta Coal Measures of New South Wales, is a bed of Carboniferous glacial deposits.

The Mesozoic system is not well developed. It is usually regarded as beginning with a fresh-water series containing the remains of fish and labyrinthodonts; but as it also contains *Vertebraria* it is probably Palaeozoic; and this series is covered by sandstones and shales which are probably of Triassic age. The most conspicuous member of the Mesozoic group is the sheet of diabase and dolerite, made up of laccolites and sills, which covers most of the central plateau of Tasmania. These rocks form the prominent scarps, known as the Tiers, on the edge of the plateau, and its outliers, such at Mount Wellington near Hobart, and the Eldon Range. This sheet of diabase has been regarded as Carboniferous; but, according to W. H. Twelvetrees, it is probably Cretaceous. The Cainozoic system includes at Table Cape an outcrop of marine beds probably of Oligocene age. Lower Cainozoic lacustrine beds with fossil plants, of the same age as those which underlie the older basalts of Victoria, occur in the valleys of northern Tasmania. The Cainozoic series includes many igneous rocks. The tinguaites and sölvsbergites of Port Cygnet, south of Hobart, may be of this age; they are intrusive in Carboniferous rocks, and there is no evidence of their precise date; but their resemblance to the rocks associated with the geburite-dacite of Victoria suggests that they may belong to the beginning of the Cainozoic volcanic period of south-eastern Australia. North-western Tasmania in Pleistocene times had an extensive series of glaciers, of which the lower moraines were deposited only about 400 feet above sea level.

The information as to the geology of Tasmania up to 1888 is collected in R. M. Johnston's *Systematic Account of the Geology of Tasmania*, which gives a bibliography up to that date. A later sketch of the island is by W. H. Twelvetrees, "Outlines of the Geology of Tasmania," *Proc. R. Soc. Tasmania*, 1900–1901, pp. 58–74. The mining literature is given in the reports of the Mines Department, and special reports issued in the Parliamentary Papers; and the economic and general geology are described in reports issued periodically by the Geological Survey, under W. H. Twelvetrees, and in papers published in the *Proceedings of the Royal Society of Tasmania*. The Mount Lyell mining field is described, with some account of the neighbouring districts of Western Tasmania, in J. W. Gregory, *The Mount Lyell Mining Field* (Melbourne, 1904). The glacial geology, with a summary of the literature thereon, is described by the same writer in the *Quarterly Journal of the Geological Society*, 1904, vol. lx., pp. 7–8, 37–53. (J. W. G.)

Climate.—Tasmania possesses a very temperate and healthy climate. The mean temperature of the year, as estimated from observations extending back to 1841, is about 50·10°. The mean at Hobart was 54·4°, at Launceston 56·6° and at Oatlands, which is in the centre of the island and 1400 ft. above sea-level, 51·76°. Snow is rarely seen except in the mountains. The average temperature at Hobart of January, the hottest month, is 63°, and of July, which is mid-winter, 45°. The western prevailing winds—particularly the north-western—carry the rain-bearing clouds. The elevation-divide between the western and eastern parts of the island rises generally to a height of between 3000 and 5000 ft., and consequently the parts to the east of such heights receive much less precipitation than those to the westward. The general average for the eastern district over a period of years was 22·07 inches; for the western, 37·55 inches; and for Tasmania 26·69 inches.

Flora.—The vegetation which prevails among the older schistose rocks of the west and extreme south presents a totally different appearance to that which occurs in the more settled districts of the east. The western vegetation, as compared with that of the east, presents as marked a contrast as do the prevailing rocks upon which it flourishes. The characteristic trees and shrubs of the west include the following genera, viz.: *Fagus*, *Cenarrhenes*, *Anodopetalum*, *Eucryphia*, *Bauera*, *Boronia*, *Agastachys*, *Richea*, *Telopea*, *Grevillea*, *Orites*, *Athrotaxis*, *Dacrydium*, *Phyllocladus*. On the eastern side the plains and rocky ridges, where not artificially cleared, are occupied by shaggy and often sombre forests mainly composed of the following genera: *Eucalyptus* (gum tree), *Casuarina*, *Bursaria*, *Acacia*, *Leptospermum*, *Drimys*, *Melaleuca*, *Dodonaea*, *Notolea*, *Exocarpus*, *Hakea*, *Epacris*, *Xanthorrhoea*, *Frenela*. The mountain slopes and ravines of the east have a well-marked vegetation. In character it is more akin to, and in many cases identical with, that of the west. The tree fern (*Dicksonia antarctica*) in the mountain ravines is especially remarkable. The following genera are also found in such positions in great luxuriance, viz.: *Fagus*, *Anopterus*, *Phebalium*, *Eucalyptus*, *Richea*, *Cyathodes*, *Pomaderris*, *Prostanthera*, *Boronia*, *Gaultheria*, *Correa*, *Bedfordia*, *Aster*, *Archeria*, *Atherosperma*, &c. In the extreme west the trees and larger shrubs do not appear to ascend the schistose rocky mountain slopes of the central and eastern parts.

Fauna.—Animal life in Tasmania is similar to that in Australia. The dingo or dog of the latter is wanting; and the Tasmanian devil and tiger, or wolf, are peculiar to the island. The Marsupials include the *Macropus* or kangaroo; the opossums, *Phalangista vulpina* and *P. Cookii*; the opossum-mouse, *Dromicia nana*; *Perameles* or bandicoot; *Hypsiprymnus* or kangaroo rat; *Phascolomys* or wombat; while of *Monotremata* there are the *Echidna* or porcupine ant-eater and the duck-billed platypus. The marsupial tiger or Tasmanian wolf (*Thylacinus cynocephalus*), 5 ft. long, is yellowish brown, with several stripes across the back, having short stiff hair and very short legs. Very few of these nocturnal carnivores are now alive to trouble flocks. The tiger-cat of the colonists, with weasel legs, white spots and nocturnal habits, is a large species of the untameable native cats. The devil (*Dasyurus* or *Sarcophilus ursinus*) is black, with white bands on neck and haunches. The covering of this savage but cowardly little night-prowler is a sort of short hair, not fur. The tail is thick, and the bull-dog mouth is formidable. Among the birds of the island are the eagle, hawk, petrel, owl, finch, peewit, diamond bird, fire-tail, robin, emu-wren, crow, swallow, magpie, blackcap, goatsucker, quail, ground dove, parrot, lark, mountain thrush, cuckoo, wattlebird, whistling duck, honeybird, Cape Barren goose, penguin duck, waterhen, snipe, albatross and laughing jackass. Snakes are pretty plentiful in scrubs; the lizards are harmless. Insects, though similar to Australian ones, are far less troublesome; many are to be admired for their great beauty.

Population.—At the beginning of 1905, the state contained 181,100 people, giving a density of 6·9 persons per square mile. The population in 1870 was 100,765. The discovery of Mount Bischoff one year later, though it greatly stimulated speculation and induced a large influx of immigrants, did not put a stop to the outflow, for in 1880 the population was still below 115,000. During the next two decades there was a substantial advance; in 1890 it had reached 145,200, and in 1900, 172,980. Like all the Australian states, Tasmania shows a decline in the birth-rate; in 1905 the births were 5256—36 less than in 1904—which gives a rate of 29·32 per 1000 of mean population.

The climate is probably more healthy than that of any of the Australian states, although, owing to the large number of old people in the colony, the death-rate would appear to put Tasmania on a par with New South Wales and South Australia. The death-rate per 1000 of population, which was 16·52 in the period 1876–80, had fallen to 11·01 in the period 1901–5. There has therefore been a gradual and substantial improvement in the health conditions of the state. The annual marriage-rate was for many years considerably below the average of Australia generally, a condition sufficiently accounted for by the continued emigration of men unmarried and of marriageable ages; this emigration had ceased in 1900, and the marriage-rate may be taken as 7·8 per thousand. The chief towns are Hobart (pop. 35,000) and Launceston (pop. 22,500).

Administration.—As one of the states of Australia, Tasmania returns six senators and five representatives to the federal parliament. The local constitution resembles that of the other Australian states inasmuch as the executive government of four ministers is responsible to the legislature, which consists of a legislative council and a house of assembly. The former is composed of eighteen members elected for six years. Electors of the council must be natural-born or naturalized subjects of the king, twenty-one years of age, resident in Tasmania for twelve months, and possessing a freehold of the annual value of £10 or a leasehold of the annual value of £30 within the electoral district; the property qualification being waived in the case of persons with university degrees or belonging to certain professions. Members of the council must be not less than thirty years of age. The house of assembly consists of 35 members elected for three years. Every resident of Tasmania for a period of twelve months who is twenty-one years of age, natural-born or naturalized, is entitled to have his name placed on the electoral roll, and to vote for the district in which he resides. The franchise has been conferred on women.

Education.—Half the population are adherents of the Church of England, and about 18 per cent. Roman Catholics; Wesleyans number nearly 16 per cent., and Presbyterians about 6½ per cent. Instruction is compulsory upon children over seven years of age and under thirteen years in the towns of Hobart and Launceston, but not in the rural districts. Special religious instruction is allowed to be given after school hours by teachers duly authorized by the various religious denominations, and this privilege is somewhat extensively used by the Church of England. The schools are not free, as small fees are charged; but these are not enforced where parents can reasonably plead poverty. In 1905 there were 343 state schools, with 19,000 pupils on the roll, and administered by 600 teachers; there were also 180 private schools, with 310 teachers and 9000 scholars. The net expenditure averages £3, 15s. 2d. per child in average attendance, inclusive of what is spent in the upkeep of school buildings and on new schools. The university of Tasmania has an endowment of £4000 and a revenue from other sources (chiefly fees) of from £1100 to £2000. The students attending lectures in 1904 were 62, of whom 51 matriculated, and the number of degrees conferred to the close of that year was 180, the great majority of these degrees being granted *ad eundem gradum*.

Finance.—The revenue is chiefly obtained through the custom-house, but the federal tariff has had the effect of considerably reducing the receipts from this source. In 1905 the state raised £852,681 on account of the public revenue, which is equal to £4, 13s. 3d. per inhabitant; of this sum £259,099 was the excess of Commonwealth collections over expenditure, and £216,953 from other taxation; the railways returned £245,049, while from public lands was obtained £63,088, and from other sources £43,504. The expenditure was £840,185, thus distributed: railway working expenses, £171,619; public instruction, £67,403; interest and charges upon debt, including sinking funds, £349,090; and other services £252,075. The interest and other debt charges come to £1, 18s. 9d. per inhabitant, and represent 41·55 per cent. of the expenditure of the state. The public debt in the year 1906 stood at £9,471,971, of which £7,830,250 was held in London; this represents £52, 6s. per inhabitant. In 1871 it was £1,315,200, in 1881 £2,003,000, and in 1891 £7,110,290, representing respectively £12, 18s., £16, 16s. 10d., and £46, 11s. 10d. per inhabitant, the great increase in recent years being due to the rapid extension of railway and other public works. The expenditure upon works may be divided into that on revenue-yielding works, viz. railways, £4,122,589, and telegraphs, £142,410; and that on works not yielding revenue, £4,970,018. For local government purposes Tasmania is divided into municipalities, town boards, and road trusts. The rates are assessed on an assumed annual value, which in 1900 was £1,417,547, corresponding to a capital value of upwards of £28,000,000. The bulk of the revenue of the local government bodies is obtained from rates. The sources of revenue in 1905 were: government endowment, £5355; local rates, £71,920; and other sources, £83,187. The outstanding loans of municipalities amount to £697,133, of which the greater portion is represented by the indebtedness of the two chief cities, Hobart and Launceston.

Defence.—Tasmania being a portion of the Commonwealth of Australia, its defence is undertaken by the federal government. The strength of the local forces is about 1500 officers and men.

Mining.—Mining is now the foremost industry, the gross production in 1905 being valued at £1,858,218 as compared with £1,500,000, the value of agricultural production, which is next in importance. Tasmania produces gold, tin, silver, copper and coal, and in 1905 the production of these minerals was valued at: gold, £312,380; silver and silver-lead, £465,094; copper, £672,010; tin, £346,092; and coal, £44,194. Beaconsfield is the chief goldfield, 26 miles north-west of Launceston. There are about 1500 persons employed mining for gold on the various fields. The Mount Zeehan and Dundas districts produce almost the whole of the silver at the present time, and most of the ore is sold to agents of the Australian and German smelting works. Tasmania is the largest producer of tin in Australasia, and a very large proportion of the tin hitherto produced has been obtained from alluvial deposits, the lodes, except at Mount Bischoff, having, comparatively speaking, been neglected. The Mount Bischoff mine, which is worked as an open quarry, is the largest producer of tin, and (with an original capital of £30,000) has paid over two millions sterling in dividends. The number of tin miners in the state is about 1170. Tasmania also takes the lead amongst the states in copper production: in 1896 there was a small production of £1659; in 1897 it grew to £317,437, in 1898 to £378,565, in 1899 to £761,880, and in 1900 to £901,660; and although the production has since been considerably reduced it is still a great industry. This expansion was chiefly due to the enterprise of the Mount Lyell Mining and Railway Company, whose mine is situated at Gormanston. Coal-mining is carried on in various districts of the island, but the principal mines are at Mount Nicholas and Cornwall, in the Mount Nicholas Range; the output of the field is increasing, but no export trade is at present possible, the mines being situated too far from the seaboard. The number of men employed in coal-mining is 150, and the output about 52,000 tons per annum.

Manufactures are on a small scale, the number of establishments being about 440, and the hands employed 9000.

Agriculture.—After being much neglected, agriculture received renewed attention in 1892 and the following years up to 1904, when the area under crop reached a total of 259,611 acres; since the year named there has been no increase, and the area cultivated may be placed at about 250,000 acres. The area under crop, at intervals of ten years, was as follows: 1861, 163,385 acres; 1871, 155,046 acres; 1887, 148,494 acres; 1891, 168,121 acres; and 1901, 224,352 acres. Wheat is the principal crop, and the yield is larger per acre and less variable than that of the Australian states: for the fifteen years ending with 1905 the average yield was 18·9 bushels per acre, ranging between 15 bushels in 1894 and 27 bushels in 1899. The oat crop is also much above the Australian average, and may be set down at 30 bushels an acre, but an average of 5 bushels higher is not infrequent. Tasmania is renowned for its fruit crops, and now that this fruit has found an opening in the British market, renewed attention is being devoted to the industry. In 1905 there were 12,683 acres of apples, 2098 acres of pears, 1111 acres of apricots, 1123 acres of plums, 426 acres of cherries, 498 acres of peaches, 2000 acres of strawberries, gooseberries and raspberries, and 1107 acres of currants. The crop for the same year included 1,100,000 bushels of apples, 75,000 bushels of pears, and nearly 170,000 bushels of other fruit. Tasmania finds its best markets for fruits in New South Wales and in Great Britain. The total value of the produce of Tasmanian farms now exceeds £1,250,000, which is equivalent to £4, 17s. 5d. per acre cultivated.

Tasmania shows a decline in sheep-breeding, yet the state is singularly well adapted for sheep-raising, and its stud flocks are well known and annually drawn upon to improve the breed in the other states. Nor have the other branches of the pastoral industry shown much expansion, as the following table will show:—

Year.	Sheep.	Horned Cattle.	Horses.	Swine.
1861	1,714,498	87,114	22,118	40,841
1871	1,305,489	101,540	23,054	52,863
1881	1,847,479	130,526	25,607	49,660
1891	1,662,801	167,666	31,262	73,520
1901	1,683,956	165,516	31,607	68,291
1905	1,583,561	206,211	37,101	72,810

Commerce.—The shipping increased considerably after 1896. Hobart is now a place of call for several of the European steamship lines, and the state is becoming increasingly popular as a summer resort for the residents of Melbourne and Sydney. The growth of the shipping trade will be seen in the following table, which also gives the imports and exports at ten-yearly intervals:—

Year.	Shipping entered.	Imports.	Exports.
	Tons.	£	£
1861	113,610	954,517	905,463
1871	107,271	778,087	740,638
1881	192,024	1,431,144	1,555,576
1891	514,706	2,051,964	1,440,818
1900	618,963	2,073,657	2,610,617
1905	1,056,256	2,651,754	3,711,616

Tasmania does a large trade with Victoria and New South Wales as well as with Great Britain. The principal exports in 1905 and their values were: wool, £401,958; gold, £187,873; tin and ore, £257,256; silver and ore, £318,971; copper, £569,052; farm, fruit and vegetable products, £477,866; timber, £78,380. The imports represent £14, 15s. 10d. and the exports £20, 14s. per inhabitant. The chief ports of the state are Hobart, where the shipping entered in 1905 amounted to 645,000 tons, and Launceston, 223,000 tons; Strahan on the west coast has also a considerable trade.

Railways.—The railways open for traffic in 1905 had a length of 619 miles, of which 463 were government and 156 private lines. The progress of railway construction will be seen from the following figures: open for traffic, 1871, 45 miles; 1881, 168 miles; 1891, 425 miles; and 1905, 619 miles. The railways, both state and private, are of 3 ft. 6 in. gauge. The capital expended on government lines up to 1905 was £3,920,500; the gross earnings in that year were £243,566, and the working expenses £171,630; leaving £71,936 as the net earnings. This last-mentioned sum is equal to 1·83 per cent. on the capital expenditure; and as the average interest upon outstanding loans is 3·73 per cent., the railways are carried on at a loss of 1·9 per cent. The private railways show somewhat better returns; the Emu Bay and Mount Bischoff line, 103 miles in length, constructed at a cost of £565,365, returned in 1904 about 3·22 per cent., and the Mount Lyell Company's railway, 22 miles long, costing £220,333, returned nearly 6 per cent.

The roads maintained by the road trusts and boards of the colony extend over 7695 miles, of which 4146 were macadamized; the annual expenditure thereon is over £35,768.

Posts and Telegraphs.—There were 379 post offices and receiving offices in 1905, and 327 telegraphic stations; 12,616,000 postcards and letters, 2,800,000 packets, and 7,200,000 newspapers were received and despatched. The postal revenue amounted to £116,132, and the expenditure to £109,389; these sums include telegraph and telephone business. The telegraph messages sent numbered 496,000. The telephone system is being rapidly extended, and at the beginning of 1906, 1371 miles of line were being worked.

Banking.—There are four banks of issue, of which two are local institutions; their united assets average £3,576,700. The note circulation is about £150,000, and the deposits £3,520,000, about half bearing interest.

History.—Tasmania, or, as it was originally called, Van Diemen's Land, was discovered in 1642 by the Dutch navigator Tasman (*q.v.*) who named the territory after his patron, Van Diemen. The island was subsequently visited in 1772 by a French naval officer, Captain Marion du Fresne; in 1773 by Captain Furneaux, of the British man-of-war "Adventure"; in 1777 by the great circumnavigator Captain Cook; by Bligh in 1788, and again in 1792, when he planted fruit trees. In the same year the French navigator D'Entrecasteaux visited the south portion of the island and surveyed the coast. In 1798 Bass sailed through the strait which now bears his name, and discovered Van Diemen's Land was an island. In 1800 the French explorer Baudin, in command of the ships "Géographe" and "Naturaliste," surveyed the south of the island, and reports of his proceedings having reached the British officials at Sydney, they determined to forestall the French and take possession of Van Diemen's Land.

In 1802 the "Cumberland," a small schooner, landed at King's Island in Bass Strait, and in 1803 Lieutenant Bowen was sent by Governor King of New South Wales to form a settlement on the south coast of Van Diemen's Land. He had aboard his two ships, the "Lady Nelson" of 60 tons and the whaler "Albion" of 306 tons, three officials, a lance-corporal and seven privates of the New South Wales Corps, six free men and twenty-five convicts, together with an adequate supply of live stock, and landed at Risdon, near Hobart, where he was joined shortly afterwards by fifteen soldiers and forty-two convicts. In 1807, Colonel Paterson occupied Port Dalrymple on the north side of the island. During the same year Colonel Collins, who had failed in an attempt to colonize the shores of Port Phillip, transferred his soldiers, convicts and officials to the neighbourhood of Hobart, and was appointed commandant of the infant settlement. Provisions were scarce and dear, communication with the rest of the world was infrequent, and in 1807 the community was threatened with starvation, and flour was sold at £200 per ton. The difficulties of the settlers were increased by the hostility of the blacks. The first collision took place at Risdon, a few days after the landing of Lieutenant Bowen's expedition, and for this the white settlers were entirely responsible. Hostilities between the races were incessant from 1802 till 1830. An attempt was made in the year 1830 to drive the natives to one corner of the island, but without success. In the following year, however, Mr George Robinson induced the remnant of the blacks to leave the mainland and take refuge, first in South Bruni and subsequently in Flinders Island, their numbers having then diminished from 5000, the original estimate of the aboriginal population, to 203. In 1842 there were only 44, in 1854 they had diminished to 16, and the last pure-blooded Tasmanian died in 1876, at the age of seventy-six. There are, however, a few persons possessing more or less aboriginal blood in some of the islands of the Bass Strait.

Some persons who had settled at Norfolk Island when that island became a penal depot were transferred to Van Diemen's Land in 1805. But the growth of population was extremely slow, and in 1808 a census showed that there were only 3240 people on the island, including officials, military and convicts, and whatever measure of prosperity was enjoyed by the free inhabitants arose from the expenditure by the imperial government upon the convict settlement. In the year named settlers began to arrive. To every free immigrant was given a tract of land in proportion to the amount of capital brought by him to the colony—the possession of £500 entitling the holder to 640 acres, and so in proportion, a very liberal view being taken as to what constituted capital. To every free settler was assigned, if desired, the services of a number of convicts proportionate to the size of his holding. These were fed and clothed by the settler in return for their labour, and the government was relieved of the expense of their support and supervision. The assignment system was eventually abandoned in consequence of its moral and economic evils, but it cannot be denied that while it lasted the colony made substantial progress. In 1821 the population had grown to 7400; the sheep numbered 128,468; the cattle, 34,790; horses, 550; and 14,940 acres of land were under crops. As the number of free settlers in the colony increased an agitation arose for more political freedom and improved administration; especially was there a demand for a free press and for trial by jury. These requests were gradually granted. Courts of justice were substituted in 1822 for courts-martial; and in 1825 the colony was made independent of New South Wales, Colonel Arthur being appointed governor. In 1828 the Van Diemen's Land Company commenced sheep-farming on a large scale in the north-west district of the island under a charter granted three years before, and in 1829 the Van Diemen's Land Establishment obtained a grant of 40,000 acres at Norfolk Plains for agriculture and grazing. In 1834 Portland Bay, on the mainland of Australia, was occupied by settlers from Van Diemen's Land, and in 1835 there was a migration, large when compared with the population of the island, to the shores of Port Phillip, now Victoria. At that date the population was 40,172, a large proportion being convicts, for in four years 15,000 prisoners had been landed. The colony was prosperous, but the free settlers were not at all satisfied with the system of government, and an agitation commenced in Van Diemen's Land, as well as in New South Wales, for the introduction of representative institutions and the abolition of transportation. This system was abolished in New South Wales in 1840, after which date the island was the receptacle for all convicts not only from the United Kingdom, but from India and the colonies, and it was not until 1853 that transportation to Van Diemen's Land finally ceased; in the same year representative institutions were introduced, the name of the colony was changed to Tasmania, and three years later the colony was granted responsible government.

The discovery of gold in Victoria produced a very remarkable effect upon Tasmania. All kinds of produce brought fabulous prices, and were exported to Victoria in such quantities that the exports rose from a value of £665,790 in 1851 to £1,509,883 in 1852, and £1,756,316 in 1853, while the population diminished in almost equal ratio. It was estimated that in 1842 there were 38,000 adult males in the colony, but in 1854 their numbers had diminished to 22,261. For many years the island was inhabited by greybeards and children; the young men and women of all classes, so soon as they had reached manhood and womanhood, crossed Bass Strait, and entered upon the wider life and the more brilliant prospects which first Victoria, and subsequently New South Wales and Queensland, afforded them. It was not till the sixties that Tasmania embarked upon a new period of prosperity. In the early days little was known about the western half of the island. Its mineral wealth was not suspected, although as far back as 1850 coal of fair quality had been found between the Dee and the Mersey rivers, and gold had been discovered in two or three localities during 1852. In 1860 two expeditions were equipped by the government for a search for gold and other minerals, and although it was some years before there was any important result, the discoveries of these explorers directed attention to the mineral wealth of the island.

The political history of the colony after the inauguration of responsible government, until it became in 1901 one of the states of Federated Australasia, was not important. State aid to religion, which was given to any denomination which would receive it, was abolished; local self-government was extended to the rural as well as to the urban districts; a policy of semi-protection was introduced; the island was connected by a submarine cable to the mainland of Australia, and thence to the rest of the civilized world; and the population, which was only 99,328 in 1870, was nearly doubled. Like her neighbours, Tasmania organized a defence force, and was able to send a contingent to South Africa in 1900. (T. A. C.)

TASSIE, JAMES (1735–1799), Scottish gem-engraver and modeller, was born of humble parentage at Pollokshaws, near Glasgow, in 1735. During his earlier years he worked as a stonemason, but, having seen the collection of paintings brought together in Glasgow by Robert and Andrew Foulis, the printers, he removed to Glasgow, attended the academy which had been established there by the brothers Foulis, and became one of the most distinguished pupils of the school. Subsequently he visited Dublin in search of commissions, and there became acquainted with Dr Quin, who had been experimenting, as an amateur, in imitating antique engraved gems in coloured pastes. He engaged Tassie as an assistant, and together they perfected the discovery of an "enamel," admirably adapted by its hardness and beauty of texture for the formation of gems and medallions. Dr Quin encouraged his assistant to try his fortune in London, and thither he repaired in 1766. At first he had a hard struggle to make his way. But he worked on steadily with the greatest care and accuracy, scrupulously destroying all impressions of his gems which were in the slightest degree inferior or defective. Gradually the beauty and artistic character of his productions came to be known. He received a commission from the empress of Russia for a collection of about 15,000 examples; all the richest cabinets in Europe were thrown open to him for purposes of study and reproduction; and his copies were frequently sold by fraudulent dealers as the original gems. He exhibited in the Royal Academy from 1769 to 1791. In 1775 he published the first catalogue of his works, a thin pamphlet detailing 2856 items. This was followed in 1791 by a large catalogue, in two volumes quarto, with illustrations etched by David Allan, and descriptive text in English and French by Rudolph Eric Raspe, enumerating nearly 16,000 pieces.

In addition to his impressions from antique gems, Tassie executed many large profile medallion portraits of his contemporaries, and these form the most original and definitely artistic class of his works. They were modelled in wax from the life or from drawings done from the life, and—when this was impossible—from other authentic sources. They were then cast in white enamel paste, the whole medallion being sometimes executed in this material; while in other cases the head only appears in enamel, relieved against a background of ground-glass tinted of a subdued colour by paper placed behind. His first large enamel portrait was that of John Dolbon, son of Sir William Dolbon, Bart., modelled in 1793 or 1794; and the series possesses great historic interest, as well as artistic value, including as it does portraits of Adam Smith, Sir Henry Raeburn, Drs James Beattie, Blair, Black and Cullen, and many other celebrated men of the latter half of the 18th century. At the time of his death, in 1799, the collection of Tassie's works numbered about 20,000 pieces.

His nephew, WILLIAM TASSIE (1777–1860), also a gem-engraver and modeller, succeeded to James Tassie's business and added largely to his collection of casts and medallions. His portrait of Pitt, in particular, was very popular, and circulated widely. When the Shakespeare Gallery, formed by Alderman Boydell, was disposed of by lottery in 1805, William Tassie was the winner of the prize, and in the same year he sold the pictures by auction for a sum of over £6000. He bequeathed to the Board of Manufactures, Edinburgh, an extensive and valuable collection of casts and medallions by his uncle and himself, along with portraits of James Tassie and his wife by David Allan, and a series of water-colour studies by George Sanders from pictures of the Dutch and Flemish schools.

(J. M. G.)

TASSO, TORQUATO (1544–1595), Italian poet, was the son of Bernardo Tasso (1493–1569), a nobleman of Bergamo, and his wife Porzia de' Rossi. He was born at Sorrento on the 11th of March 1544. His father had for many years been secretary in the service of the prince of Salerno, and his mother was closely connected with the most illustrious Neapolitan families. The prince of Salerno came into collision with the Spanish government of Naples, was outlawed, and was deprived of his hereditary fiefs. In this disaster of his patron Tasso's father shared. He was proclaimed a rebel to the state, together with his son Torquato, and his patrimony was sequestered. These things happened during the boy's childhood. In 1552 he was living with his mother and his only sister Cornelia at Naples, pursuing his education under the Jesuits, who had recently opened a school there. The precocity of intellect and the religious fervour of the boy attracted general admiration. At the age of eight he was already famous. Soon after this date he joined his father, who then resided in great indigence, an exile and without occupation, in Rome. News reached them in 1556 that Porzia Tasso had died suddenly and mysteriously at Naples. Her husband was firmly convinced that she had been poisoned by her brother with the object of getting control over her property. As it subsequently happened, Porzia's estate never descended to her son; and the daughter Cornelia married below her birth, at the instigation of her maternal relatives. Tasso's father was a poet by predilection and a professional courtier. When, therefore, an opening at the court of Urbino offered in 1557, Bernardo Tasso gladly accepted it. The young Torquato, a handsome and brilliant lad, became the companion in sports and studies of Francesco Maria della Rovere, heir to the dukedom of Urbino. At Urbino a society of cultivated men pursued the aesthetical and literary studies which were then in vogue. Bernardo Tasso read cantos of his *Amadigi* to the duchess and her ladies, or discussed the merits of Homer and Virgil, Trissino and Ariosto, with the duke's librarians and secretaries. Torquato grew up in an atmosphere of refined luxury and somewhat pedantic criticism, both of which gave a permanent tone to his character. At Venice, whither his father went to superintend the printing of the *Amadigi* (1560), these influences continued. He found himself the pet and prodigy of a distinguished literary circle. But Bernardo had suffered in his own career so seriously from addiction to the Muses and a prince that he now determined on a lucrative profession for his son. Torquato was sent to study law at Padua. Instead of applying himself to law, the young man bestowed all his attention upon philosophy and poetry. Before the end of 1562 he had produced a narrative poem called *Rinaldo*, which was meant to combine the regularity of the Virgilian with the attractions of the romantic epic. In the attainment of this object, and in all the minor qualities of style and handling, *Rinaldo* showed such marked originality that its author was proclaimed the most promising poet of his time. The flattered father allowed it to be printed; and, after a short period of study at Bologna, he consented to his son's entering the service of Cardinal Luigi d'Este. In 1565, then, Torquato for the first time set foot in that castle at Ferrara which was destined for him to be the scene of so many glories, and such cruel sufferings. After the publication of *Rinaldo* he had expressed his views upon the epic in some *Discourses on the Art of Poetry*, which committed him to a distinct theory and gained for him the additional celebrity of a philosophical critic. The age was nothing if not critical; but it may be esteemed a misfortune for the future author of the *Gerusalemme* that he should have started with pronounced opinions upon art. Essentially a poet of impulse and instinct, he was hampered in production by his own rules.

The five years between 1565 and 1570 seem to have been the happiest of Tasso's life, although his father's death in 1569 caused his affectionate nature profound pain. Young, handsome, accomplished in all the exercises of a well-bred gentleman, accustomed to the society of the great and learned, illustrious by his published works in verse and prose, he became the idol of the most brilliant court in Italy. The princesses Lucrezia and Leonora d'Este, both unmarried, both his seniors by about ten years, took him under their protection. He was admitted to their familiarity, and there is some reason to think that neither of them was indifferent to him personally. Of the celebrated story of his love for Leonora this is not the place to speak. It is enough at present to observe that he owed much to the constant kindness of both sisters. In 1570 he travelled to Paris with the cardinal. Frankness of speech and a certain habitual want of tact caused a disagreement with his worldly patron. He left France next year, and took service under Duke Alfonso II. of Ferrara. The most important events in Tasso's biography during the following four years are the publication of the *Aminta* in 1573 and the completion of the *Gerusalemme Liberata* in 1574. The *Aminta* is a pastoral drama of very simple plot, but of exquisite lyrical charm. It appeared at the critical moment when modern music, under Palestrina's impulse, was becoming the main art of Italy. The honeyed melodies and sensuous melancholy of *Aminta* exactly suited and interpreted the spirit of its age. We may regard it as the most decisively important of Tasso's compositions, for its influence, in opera and cantata, was felt through two successive centuries. The *Gerusalemme Liberata* occupies a larger space in the history of European literature, and is a more considerable work. Yet the commanding qualities of this epic poem, those which revealed Tasso's individuality, and which made it immediately pass into the rank of classics, beloved by the people no less than by persons of culture, are akin to the lyrical graces of *Aminta*. It was finished in Tasso's thirty-first year; and when the MS. lay before him the best part of his life was over, his best work had been already accomplished. Troubles immediately began to gather round him. Instead of having the courage to obey his own instinct, and to publish the *Gerusalemme* as he had conceived it, he yielded to the critical scrupulosity which formed a secondary feature of his character. The poem was sent in manuscript to several literary men of eminence, Tasso expressing his willingness to hear their strictures and to adopt their suggestions unless he could convert them to his own views. The result was that each of these candid friends, while expressing in general high admiration for the epic, took some exception to its plot, its title, its moral tone, its episodes or its diction, in detail. One wished it to be more regularly classical; another wanted more romance. One hinted that the Inquisition would not tolerate its supernatural machinery; another demanded the excision of its most charming passages—the loves of Armida, Clorinda and Erminia. Tasso had to defend himself against all these ineptitudes and pedantries, and to accommodate his practice to the theories he had rashly expressed. As in the *Rinaldo*, so also in the *Jerusalem Delivered*, he aimed at ennobling the Italian epic style by preserving strict unity of plot and heightening poetic diction. He chose Virgil for his model, took the first crusade for subject, infused the fervour of religion into his conception of the hero Godfrey. But his own natural bias was for romance. In spite of the poet's ingenuity and industry the stately main theme evinced less spontaneity of genius than the romantic episodes with which, as also in *Rinaldo*, he adorned it. Godfrey, a mixture of pious Aeneas and Tridentine Catholicism, is not the real hero of the *Gerusalemme*. Fiery and passionate Rinaldo, Ruggiero, melancholy impulsive Tancredi, and the chivalrous Saracens with whom they clash in love and war, divide our interest and divert it from Goffredo. On Armida, beautiful witch, sent forth by the infernal senate to sow discord in the Christian camp, turns the action of the epic. She is converted to the true faith by her adoration for a crusading knight, and quits the scene with a phrase of the Virgin Mary on her lips. Brave Clorinda, donning armour like Marfisa, fighting in duel with her devoted lover, and receiving baptism from his hands in her pathetic death; Erminia seeking refuge in the shepherd's hut—these lovely pagan women, so touching in their sorrows, so romantic in their adventures, so tender in their emotions, rivet our attention, while we skip the battles, religious ceremonies, conclaves and stratagems of the campaign. The truth is that Tasso's great invention as an artist was the poetry of sentiment. Sentiment, not sentimentality, gives value to what is immortal in the *Gerusalemme*. It was a new thing in the 16th century, something concordant with a growing feeling for woman and with the ascendant art of music. This sentiment, refined, noble, natural, steeped in melancholy, exquisitely graceful, pathetically touching, breathes throughout the episodes of the *Gerusalemme*, finds metrical expression in the languishing cadence of its mellifluous verse, and sustains the ideal life of those seductive heroines whose names were familiar as household words to all Europe in the 17th and 18th centuries.

Tasso's self-chosen critics were not men to admit what the public has since accepted as incontrovertible. They vaguely felt that a great and beautiful romantic poem was imbedded in a dull and not very correct epic. In their uneasiness they suggested every course but the right one, which was to publish the *Gerusalemme* without further dispute. Tasso, already overworked by his precocious studies, by exciting court-life and exhausting literary industry, now grew almost mad with worry. His health began to fail him. He complained of headache, suffered from malarious fevers, and wished to leave Ferrara. The *Gerusalemme* was laid in manuscript upon a shelf. He opened negotiations with the court of Florence for an exchange of service. This irritated the duke of Ferrara. Alfonso hated nothing more than his courtiers leaving him for a rival duchy. He thought, moreover, that, if Tasso were allowed to go, the Medici would get the coveted dedication of that already famous epic. Therefore he bore with the poet's humours, and so contrived that the latter should have no excuse for quitting Ferrara. Meanwhile, through the years 1575, 1576, 1577, Tasso's health grew worse. Jealousy inspired the courtiers to calumniate and insult him. His irritable and suspicious temper, vain and sensitive to slights, rendered him only too easy a prey to their malevolence. He became the subject of delusions,—thought that his servants betrayed his confidence, fancied he had been denounced to the Inquisition, expected daily to be poisoned. In the autumn of 1576 he quarrelled with a Ferrarese gentleman, Maddalo, who had talked too freely about some love affair; in the summer of 1577 he drew his knife upon a servant in the presence of Lucrezia d'Este, duchess of Urbino. For this excess he was arrested; but the duke released him, and took him for change of air to his country seat of Belriguardo. What happened there is not known. Some biographers have surmised that a compromising *liaison* with Leonora d'Este came to light, and that Tasso agreed to feign madness in order to cover her honour. But of this there is no proof. It is only certain that from Belriguardo he returned to a Franciscan convent at Ferrara, for the express purpose of attending to his health. There the dread of being murdered by the duke took firm hold on his mind. He escaped at the end of July, disguised himself as a peasant, and went on foot to his sister at Sorrento.

The truth seems to be that Tasso, after the beginning of 1575, became the victim of a mental malady, which, without amounting to actual insanity, rendered him fantastical and insupportable, a misery to himself and a cause of anxiety to his patrons. There is no evidence whatsoever that this state of things was due to an overwhelming passion for Leonora. The duke, instead of acting like a tyrant, showed considerable forbearance. He was a rigid and not sympathetic man, as egotistical as a princeling of that age was wont to be. But to Tasso he was never cruel—hard and unintelligent perhaps, but far from being that monster of ferocity which has been painted. The subsequent history of his connexion with the poet, over which we may pass rapidly, will corroborate this view. While at Sorrento, Tasso hankered after Ferrara. The court-made man could not breathe freely outside its charmed circle. He wrote humbly requesting to be taken back. Alfonso consented, provided Tasso would agree to undergo a medical course of treatment for his melancholy. When he returned, which he did with alacrity under those conditions, he was well received by the ducal family. All might have gone well if his old maladies had not revived. Scene followed scene of irritability, moodiness, suspicion, wounded vanity and violent outbursts. In the summer of 1578 he ran away again; travelled through Mantua, Padua, Venice, Urbino, Lombardy. In September he reached the gates of Turin on foot, and was courteously entertained by the duke of Savoy. Wherever he went, "wandering like the world's rejected guest," he met with the honour due to his illustrious name. Great folk opened their houses to him gladly, partly in compassion, partly in admiration of his genius. But he soon wearied of their society, and wore their kindness out by his querulous peevishness. It seemed, moreover, that life was intolerable to him outside Ferrara. Accordingly he once more opened negotiations with the duke; and in February 1579 he again set foot in the castle. Alfonso was about to contract his third marriage, this time with a princess of the house of Mantua. He had no children; and, unless he got an heir, there was a probability that his state would fall, as it did subsequently, to the Holy See. The nuptial festivals, on the eve of which Tasso arrived, were not therefore the occasion of great rejoicing to the elderly bridegroom. As a forlorn hope he had to wed a third wife; but his heart was not engaged and his expectations were far from sanguine. Tasso, preoccupied as always with his own sorrows and his own sense of dignity, made no allowance for the troubles of his master. Rooms below his rank, he thought, had been assigned him.

The princesses did not want to see him. The duke was engaged. Without exercising common patience, or giving his old friends the benefit of a doubt, he broke into terms of open abuse, behaved like a lunatic, and was sent off without ceremony to the madhouse of St Anna. This happened in March 1579; and there he remained until July 1586. Duke Alfonso's long-sufferance at last had given way. He firmly believed that Tasso was insane, and he felt that if he were so St Anna was the safest place for him. Tasso had put himself in the wrong by his intemperate conduct, but far more by that incomprehensible yearning after the Ferrarese court which made him return to it again and yet again. It would be pleasant to assume that an unconquerable love for Leonora led him back. Unfortunately, there is no proof of this. His relations to her sister Lucrezia were not less intimate and affectionate than to Leonora. The lyrics he addressed to numerous ladies are not less respectful and less passionate than those which bear her name. Had he compromised her honour, the duke would certainly have had him murdered. Custom demanded this retaliation, and society approved of it. If therefore Tasso really cherished a secret lifelong devotion to Leonora, it remains buried in impenetrable mystery. He did certainly not behave like a loyal lover, for both when he returned to Ferrara in 1578 and in 1579 he showed no capacity for curbing his peevish humours in the hope of access to her society.

It was no doubt very irksome for a man of Tasso's pleasure-loving, restless and self-conscious spirit to be kept for more than seven years in confinement. Yet we must weigh the facts of the case rather than the fancies which have been indulged regarding them. After the first few months of his incarceration he obtained spacious apartments, received the visits of friends, went abroad attended by responsible persons of his acquaintance, and corresponded freely with whomsoever he chose to address. The letters written from St Anna to the princes and cities of Italy, to warm well-wishers, and to men of the highest reputation in the world of art and learning, form our most valuable source of information, not only on his then condition, but also on his temperament at large. It is singular that he spoke always respectfully, even affectionately, of the duke. Some critics have attempted to make it appear that he was hypocritically kissing the hand which had chastised him, with the view of being released from prison. But no one who has impartially considered the whole tone and tenor of his epistles will adopt this opinion. What emerges clearly from them is that he laboured under a serious mental disease, and that he was conscious of it.

Meanwhile he occupied his uneasy leisure with copious compositions. The mass of his prose dialogues on philosophical and ethical themes, which is very considerable, we owe to the years of imprisonment in St Anna. Except for occasional odes or sonnets—some written at request and only rhetorically interesting, a few inspired by his keen sense of suffering and therefore poignant—he neglected poetry. But everything which fell from his pen during this period was carefully preserved by the Italians, who, while they regarded him as a lunatic, somewhat illogically scrambled for the very offscourings of his wit. Nor can it be said that society was wrong. Tasso had proved himself an impracticable human being; but he remained a man of genius, the most interesting personality in Italy. Long ago his papers had been sequestered. Now, in the year 1580, he heard that part of the *Gerusalemme* was being published without his permission and without his corrections. Next year the whole poem was given to the world, and in the following six months seven editions issued from the press. The prisoner of St Anna had no control over his editors; and from the masterpiece which placed him on the level of Petrarch and Ariosto he never derived one penny of pecuniary profit. A rival poet at the court of Ferrara undertook to revise and re-edit his lyrics in 1582. This was Battista Guarini; and Tasso, in his cell, had to allow odes and sonnets, poems of personal feeling, occasional pieces of compliment, to be collected and emended, without lifting a voice in the matter. A few years later, in 1585, two Florentine pedants of the Della Crusca academy declared war against the *Gerusalemme.* They loaded it with insults, which seem to those who read their pamphlets now mere parodies of criticism. Yet Tasso felt bound to reply; and he did so with a moderation and urbanity which prove him to have been not only in full possession of his reasoning faculties, but a gentleman of noble manners also. Certainly the history of Tasso's incarceration at St Anna is one to make us pause and wonder. The man, like Hamlet, was distraught through ill-accommodation to his circumstances and his age; brain-sick he was undoubtedly; and this is the duke of Ferrara's justification for the treatment he endured. In the prison he bore himself pathetically, peevishly, but never ignobly. He showed a singular indifference to the fate of his great poem, a rare magnanimity in dealing with its detractors. His own personal distress, that terrible *malaise* of imperfect insanity, absorbed him. What remained over, untouched by the malady, unoppressed by his consciousness thereof, displayed a sweet and gravely-toned humanity. The oddest thing about his life in prison is that he was always trying to place his two nephews, the sons of his sister Cornelia, in court-service. One of them he attached to the duke of Mantua, the other to the duke of Parma. After all his father's and his own lessons of life, he had not learned that the court was to be shunned like Circe by an honest man. In estimating Duke Alfonso's share of blame, this wilful idealization of the court by Tasso must be taken into account. That man is not a tyrant's victim who moves heaven and earth to place his sister's sons with tyrants.

In 1586 Tasso left St Anna at the solicitation of Vincenzo Gonzaga, prince of Mantua. He followed his young deliverer to the city by the Mincio, basked awhile in liberty and courtly pleasures, enjoyed a splendid reception from his paternal town of Bergamo, and produced a meritorious tragedy called *Torrismondo.* But only a few months had passed when he grew discontented. Vincenzo Gonzaga, succeeding to his father's dukedom of Mantua, had scanty leisure to bestow upon the poet. Tasso felt neglected. In the autumn of 1587 we find him journeying through Bologna and Loreto to Rome, and taking up his quarters there with an old friend, Scipione Gonzaga, now patriarch of Jerusalem. Next year he wandered off to Naples, where he wrote a dull poem on *Monte Oliveto.* In 1589 he returned to Rome, and took up his quarters again with the patriarch of Jerusalem. The servants found him insufferable, and turned him out of doors. He fell ill, and went to a hospital. The patriarch in 1590 again received him. But Tasso's restless spirit drove him forth to Florence. The Florentines said, "Actum est de eo." Rome once more, then Mantua, then Florence, then Rome, then Naples, then Rome, then Naples—such is the weary record of the years 1590–94. We have to study a veritable Odyssey of malady, indigence and misfortune. To Tasso everything came amiss. He had the palaces of princes, cardinals, patriarchs, nay popes, always open to him. Yet he could rest in none. Gradually, in spite of all veneration for the *sacer vates*, he made himself the laughing-stock and bore of Italy.

His health grew ever feebler and his genius dimmer. In 1592 he gave to the public a revised version of the *Gerusalemme.* It was called the *Gerusalemme Conquistata.* All that made the poem of his early manhood charming he rigidly erased. The versification was degraded; the heavier elements of the plot underwent a dull rhetorical development. During the same year a prosaic composition in Italian blank verse, called *Le Sette Giornate*, saw the light. Nobody reads it now. We only mention it as one of Tasso's dotages—a dreary amplification of the first chapter of Genesis.

It is singular that just in these years, when mental disorder, physical weakness, and decay of inspiration seemed dooming Tasso to oblivion, his old age was cheered with brighter rays of hope. Clement VIII. ascended the papal chair in 1592. He and his nephew, Cardinal Aldobrandini of St Giorgio, determined to befriend our poet. In 1594 they invited him to Rome. There he was to assume the crown of bays, as Petrarch had assumed it, on the Capitol. Worn out with illness, Tasso reached Rome in November. The ceremony of his coronation was deferred because Cardinal Aldobrandini had fallen ill. But the pope assigned him a pension; and, under the pressure of pontifical remonstrance, Prince Avellino, who held Tasso's maternal estate, agreed to discharge a portion of his claims by payment of a yearly rent-charge. At no time since Tasso left St Anna had the heavens apparently so smiled upon him. Capitolian honours and money were now at his disposal. Yet fortune came too late. Before the crown was worn or the pensions paid he ascended to the convent of St Onofrio, on a stormy 1st of April in 1595. Seeing a cardinal's coach toil up the steep Trasteverine Hill, the monks came to the door to greet it. From the carriage stepped Tasso, the Odysseus of many wanderings and miseries, the singer of sweetest strains still vocal, and told the prior he was come to die with him.

In St Onofrio he died, on the 25th of April 1595. He was just past fifty-one; and the last twenty years of his existence had been practically and artistically ineffectual. At the age of thirty-one the *Gerusalemme*, as we have it, was accomplished. The world too was already ringing with the music of *Aminta*. More than this Tasso had not to give to literature. But those succeeding years of derangement, exile, imprisonment, poverty and hope deferred endear the man to us. Elegiac and querulous as he must always appear, we yet love Tasso better because he suffered through nearly a quarter of a century of slow decline and unexplained misfortune. (J. A. S.)

Taken altogether, the best complete edition of Tasso's writings is that of Rosini (Pisa), in 33 vols. The prose works (in 2 vols., Florence, Le Monnier, 1875) and the letters (in 5 vols., same publisher, 1853) were admirably edited by Cesare Guasti. This edition of Tasso's *Letters* forms by far the most valuable source for his biography. No student can, however, omit to use the romantic memoir attributed to Tasso's friend, Marchese Manso (printed in Rosini's edition of Tasso's works above cited), and the important *Vita di Torquato Tasso* by Serassi (Bergamo, 1790). See also Solerti's *Life* (1895), his editions of the *Opere Minori in versi* (1891 et seq.), and *Gerusalemme* (1895), and his bibliography, in the *Rivista biblioteche e archivi* (1895), on the occasion of the celebration of the tercentenary of Tasso's death.

TASSONI, ALESSANDRO (1565–1635), Italian poet, was a native of Modena, where he was born and died. From 1599 till 1608 he was secretary to Cardinal Ascanio Colonna, and in this capacity saw some diplomatic service; he was afterwards employed for some time in similar occupations by Charles Emmanuel, duke of Savoy. His best-known literary work is a burlesque epic entitled *La Secchia Rapita*, or "The Rape of the Bucket" (1622), the reference being to a raid of the Modenese upon the people of Bologna in 1325, when a bucket was carried off as a trophy. As in Butler's *Hudibras*, many of the personal and local allusions in this poem are now very obscure, and are apt to seem somewhat pointless to the general reader, but, in spite of Voltaire's contempt, it cannot be neglected by any systematic student of Italian literature (see Carducci's edition, 1861). Other characteristic works of Tassoni are his *Pensieri Diversi* (1612), in which he treats philosophical, literary, historical and scientific questions with unusual freedom, and his *Considerazioni sopra il Petrarcha* (1609), a piece of criticism showing great independence of traditional views.

TASTE (from Lat. *taxare*, to touch sharply; *tangere*, to touch), in physiology, the sensation referred to the mouth when certain soluble substances are brought into contact with the mucous membrane of that cavity. By analogy, the word "taste" is used also of aesthetic appreciation (see AESTHETICS) and a sense of beauty—commonly with the qualifications "good taste" and "bad taste."

The physiological sense is located almost entirely in the tongue. Three distinct sensations are referable to the tongue—(1) taste, (2) touch, and (3) temperature. The posterior part of its surface, where there is a Λ-shaped group of large papillae, called circumvallate papillae, supplied by the glosso-pharyngeal nerve, and the tip and margins of the tongue, covered with filiform (touch) papillae and fungiform papillae, are the chief localities where taste is manifested, but it also exists in the glosso-palatine arch and the lateral part of the soft palate. The middle of the tongue and the surface of the hard palate are devoid of taste. The terminal organs of taste consist of peculiar bodies named taste-bulbs or taste-goblets, discovered by Schwalbe and S. L. Lovèn in 1867. They can be most easily demonstrated in the *papillae foliatae*, large oval prominences found on each side near the base of the tongue in the rabbit. Each papilla consists of a series of laminae or folds, in the sides of which the taste-bodies are readily displayed in a transverse section. Taste-bodies are also found on the lateral aspects of the circumvallate papillae (see Fig. 1), in the fungiform papillae,

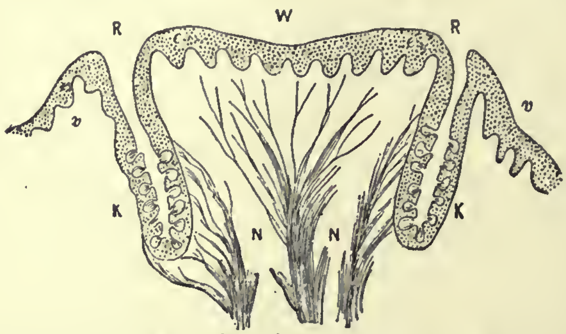

FIG. 1.—Transverse section of a circumvallate papilla: W, the papilla; *v*, *v*, the wall in section; R, R, the circular slit or fossa; K, K, the taste-bulbs in position; N, N, the nerves.

in the papillae of the soft palate and uvula, the under surface of the epiglottis, the upper part of the posterior surface of the epiglottis, the inner sides of the arytenoid cartilages, and even in the vocal cords.

The taste-bulbs are minute oval bodies, somewhat like an old-fashioned Florence flask, about $\frac{1}{300}$ inch in length by $\frac{1}{800}$ in breadth. Each consists of two sets of cells—an *outer* set, nucleated, fusiform, bent like the staves of a barrel, and arranged side by side so as to leave a small opening at the apex (the mouth of the barrel), called the gustatory pore; and an *inner* set, five to ten in number, lying in the centre, pointed at the end next the gustatory pore, and branched at the other extremity. The branched ends are continuous with non-medullated nerve fibres from the gustatory nerve. These taste-bodies are found in immense numbers: as many as 1760 have been counted on one circumvallate papilla in the ox. The proofs that these are the terminal organs of taste rest on careful observations which have shown (1) that taste is only experienced when the sapid substance is allowed to come into contact with the taste-body, and that the sense is absent or much weakened in those areas of mucous membrane where these are deficient; (2) that they are most abundant where the sense is most acute; and (3) that section of the glosso-pharyngeal nerve which is known to be distributed to the areas of mucous membrane where taste is present is followed by degeneration of the taste-bodies. At the same time it cannot be asserted that they are absolutely essential to taste, as we can hardly suppose that those animals which have no special taste-bodies are devoid of the sense.

Evidence is accumulating that taste depends on nervous impulses excited by chemical change. Substances that have taste must be soluble. Chemical changes are in all probability set up in the taste-cells, or in the processes connected with them. Some progress has been made in the attempt to establish a connexion between the chemical composition of sapid substances and the different kinds of taste to which they may give rise. Thus acids are usually sour; alkaloids have a peculiar soapy taste; salts may be sweet, like sugar of lead, or bitter, like sulphate of magnesia; soluble alkaloids, such as quinine or strychnine, are usually bitter; and the higher alcohols are more or less sweet. Substances which taste sweet or bitter often contain definite groups in the molecule, especially in the hydroxyl (HO) and amido (NH_2) groups. By altering the chemical composition of a substance having a characteristic taste (changing the position or relations of the radicles), the substance may become tasteless or intensely bitter. The sensation of taste may also be excited mechanically, as by smartly tapping the tongue, or by the stimulus of a continuous current. In the latter case electrolytic change may be the exciting cause; but that the sense organs may be stimulated electrically is proved by the fact that rapidly interrupted induced currents, which produce little or no electrolysis, may also excite taste. Sensations of taste are heightened by increasing the area of the tongue affected, and by mechanical stimulation, as when the tongue is pressed against the lips, cheeks or palate. A temperature of about 40° C. is most favourable, either extreme heat or cold apparently benumbing the sense for a time. Gustatory sensations affect each other: that is to say, a strong taste will affect the taste of another body taken immediately after it. Thus sweetness will modify bitterness, and sourness will modify both. Moreover, the application of a sapid substance to the tongue will affect taste in other parts. If the same taste is excited on each side of the tongue, although there are two sets of gustatory nerves, one for each lateral half, the sensations are blended into one; while if two different substances, say one sweet and the other bitter, are simultaneously applied, one to each side, the observer can distinctly differentiate the one from the other.

Tastes have been variously classified. One of the most useful classifications is into sweet, bitter, acid and saline tastes. Insoluble substances, when brought into contact with the tongue, give rise to feelings of touch or of temperature, but excite no taste. If solutions of various substances are gradually diluted with water until no taste is experienced, G. G. Valentin found that the sensations of taste disappeared in the following order—syrup, sugar, common salt, aloes, quinine, sulphuric acid; and Camerer found that the taste of quinine still continued although diluted with twenty times more water than common salt. The time required to excite taste after the sapid substance was placed on the tongue varies. Thus saline matters are tasted most rapidly (·17 second), then sweet, acid and bitter (·258 second). There are many curious examples of substances of very different chemical constitutions having similar tastes. For example, sugar, acetate of lead and the vapour of chloroform have all a sweetish taste. A temperature of from 50° to 90° F. is the most favourable to the sense, water above or below this temperature either masking or temporarily paralysing it.

As a general rule, bitter tastes are most acute at the back of the tongue, near the circumvallate papillae, and sweet tastes at the tip, but there are considerable individual variations. Some persons taste both bitter and sweet substances best at the back, while others taste bitter things at the tip. Many experience salt tastes best at the tip, and acid tastes at the sides of the tongue. When we consider that there are three kinds of papillae on the surface of the tongue, one would expect to meet with different degrees of sensitiveness to different tastes, even while we admit that the papillae may also have to do with sensations of touch and of temperature. By experimenting with fine capillary tubes containing sapid substances, observations have been made with individual papillae. Some are found to be sensitive to many tastes, others to two or three, others to only one, while others are insensitive to taste altogether. Again, it has been found that a mixture of sapid substances, say of quinine and sugar, may taste sweet when applied to one papilla and bitter when applied to another. The inference must be that there are special terminal organs for different tastes. Assuming that there are different kinds of taste-cells, it might be possible to paralyse some without affecting others, and thus different sensations of taste might be discriminated. This has been done by the use of the leaves of a common Indian plant, *Gymnema sylvestre*. If some of these be chewed, it has been found that bitters and sweets are paralysed (neither quinine nor sugar giving rise to sensation), while acids and salines are unaffected. Again, certain strengths of decoctions of the leaves appear to paralyse sweets sooner than bitters. These observations show the existence of different taste-cells for sweets, bitters, acids and salines; and it is clear that the region of the tongue most richly supplied with taste-cells sensitive to sweets will respond best to sweet substances, while another region, supplied by taste-cells sensitive to bitters, will respond best to bitter substances. In like manner the argument may be applied to other tastes. Suppose, again, a set of taste-cells sensitive to bitter substances: it is conceivable that in whatever way these were irritated, a bitter taste would result. If so, a substance which, applied to one part of the tongue, would cause a sweet sensation, might cause a bitter if applied to a part of the tongue richly supplied with taste-cells sensitive to bitters. This may explain why sulphate of magnesia excites at the root of the tongue a bitter taste, while applied to the tip it causes a sweet or an acid taste. Saccharine, a peculiar toluene derivative, in like manner is sweet to the tip and bitter to the back of the tongue. It has also been found that if the sweet and bitter taste-cells are paralysed by *Gymnema*, electrical irritation of the tip by a weak interrupted current does not give rise to an acid taste mixed with sweet, as it usually does, but to sensations somewhat different, which may be described as metallic or salt or acid. This experiment indicates that the action of the interrupted current on the terminal organ is analogous to the action of sweet or bitter substances (Shore). No direct observations of importance have yet been made on single circumvallate papillae. Further experiments with capillary tubes show that fungiform papillae destitute of taste buds, and areas of the surface of the tongue having neither papillae nor taste buds, may still, when stimulated by sapid substances, give rise to tastes. Taste is often associated with smell (*q.v.*), giving rise to a sensation of *flavour*, and we are frequently in the habit of confounding the one sensation with the other. Chloroform excites taste alone, whilst garlic, asafoetida and vanilla excite only smell. This is illustrated by the familiar experiment of blindfolding a person and touching the tongue successively with slices of an apple and of an onion. In these circumstances the one cannot be distinguished from the other when the nose is firmly closed. Taste may be educated to a remarkable extent; and careful observation—along with the practice of avoiding all substances having a very pronounced taste or having an irritating effect—enables tea-tasters and wine-tasters to detect slight differences of taste, more especially when combined with odour so as to produce flavour, which would be quite inappreciable to an ordinary palate. As to the action of electrical currents on taste, observers have arrived at uncertain results. So long ago as 1752 J. G. Sulzer stated that a constant current caused, more especially at the moments of opening and of closing the current, a sensation of acidity at the anode (+ pole) and of alkalinity at the katode (−pole). This is in all probability due to electrolysis, the decomposition products exciting the taste-bodies. Rapidly interrupted currents fail to excite the sense.

Disease of the tongue causing unnatural dryness may interfere with taste. Substances circulating in the blood may give rise to subjective sensations of taste. Thus santonine, morphia and biliary products (as in jaundice) usually cause a bitter sensation, whilst the sufferer from diabetes is distressed by a persistent sweetish taste. The insane frequently have subjective tastes, which are real to the patient, and frequently cause much distress. In such cases, the sensation is excited by changes in the taste-centres of the brain. Increase in the sense of taste is called *hypergeusia*, diminution of it *hypogeusia*, and its entire loss *ageusia.* Rare cases occur where there is a subjective taste not associated with insanity nor with the circulation of any known sweetish matters in the blood, possibly caused by irritation of the gustatory nerves or by changes in the nerve centres.

For the anatomy of the organs of taste, see the articles MOUTH and TONGUE. (J. G. M.)

TATA, JAMSETJI NASARWANJI (1839–1904), Parsee merchant and philanthropist, was born at Nosari, in the state of Baroda, in 1839, and went as a boy to Bombay, where he was educated at the Elphinstone College. In 1858 he entered his father's office, and began a commercial career of the highest eminence, beginning with cotton mills at Bombay and also at Nagpur, and ending with the formation of a company to work the iron ores of the Central Provinces on modern principles. One of his best-known achievements was the lowering of the freights on Indian goods to China and Japan, as the result of a long struggle with the Nippon Yusen Kaisha Co. He also introduced a silk industry after Japanese methods into Mysore, and built the Taj Mahal hotel in Bombay. But his greatest benefaction is the endowment of a research institute at Bangalore. He died at Nauheim, in Germany, on the 19th of May 1904.

TATAR PAZARJIK, or TATAR BAZARDJIK, a town of Bulgaria in Eastern Rumelia; on the river Maritza, and on the Sofia-Constantinople railway, 74 m. E.S.E. of Sofia and 23 m. W. of Philippopolis. Pop. (1906) 17,549. Situated at the junction of several roads, Tatar Pazarjik began to acquire commercial importance in the 15th century. Rice, millet and tobacco are largely cultivated in the surrounding lowlands, and there is some trade in cocoons and wool.

TATARS (the common form Tartars is less correct), a name given to nearly three million inhabitants of the Russian empire, chiefly Moslem and of Turkish origin. The majority—in European Russia—are remnants of the Mongol invasion of the 13th century (see MONGOLS), while those who inhabit Siberia are survivals of the once much more numerous Turkish population of the Ural-Altaic region, mixed to some extent with Finnish and Samoyedic stems, as also with Mongols. The name is derived from that of the Ta-ta Mongols, who in the 5th century inhabited the north-eastern Gobi, and, after subjugation in the 9th century by the Khitans, migrated southward, there founding the Mongol empire under JENGHIZ KHAN (*q.v.*). Under the leadership of his grandson (Batu) they moved westwards, driving with them many stems of the Turkish Ural-Altaians towards the plains of Russia. The ethnographical features of the present Tatar inhabitants of European Russia, as well as their language, show that they contain no admixture (or very little) of Mongolian blood, but belong to the Turkish branch of the Ural-Altaic stock, necessitating the conclusion that only Batu, his warriors, and a limited number of his followers were Mongols, while the great bulk of the 13th century invaders were Turks. On the Volga they mingled with remnants of the old Bulgarian empire, and elsewhere with Finnish stems, as well as with remnants of the ancient Italian and Greek colonies in Crimea and Caucasians in Caucasus. The name of Tatars, or Tartars, given to the invaders, was afterwards extended so as to include different stems of the same Turkish branch in Siberia, and even the bulk of the inhabitants of the high plateau of Asia and its N.W. slopes, described under the general name of Tartary. This last name has almost disappeared from geographical literature, but the name Tatars, in the above limited sense, remains in full use.

The present Tatar inhabitants of the Russian empire form three large groups—those of European Russia and Poland, those of Caucasus, and those of Siberia. The discrimination of the separate stems included under the name is still far from completion. The following subdivisions, however, may be regarded as established. (1) The Kazañ Tatars, descendants of the Kipchaks settled on the Volga in the 13th century, where they mingled with survivors of the old Bulgarians and partly with Finnish stems. They number about half a million in the government of Kazañ, about 100,000 in each of the governments of Ufa, Samara and Simbirsk, and about 300,000 in Vyatka, Saratov, Tambov, Penza, Nizhniy-Novgorod, Perm and Orenburg; some 15,000 belonging to the same stem have migrated to Ryazañ, or have been settled as prisoners in the 16th and 17th centuries in Lithuania (Vilna, Grodno and Podolia); and there are some 2000 in St Petersburg, where they pursue the callings of coachmen and waiters in restaurants. In Poland they constitute 1 per cent. of the population of the district of Plock. The Kazañ Tatars speak a pure Turkish dialect; they are middle-sized, broad-shouldered and strong, and mostly have black eyes, a straight nose and salient cheek bones. They are Mahommedans; polygamy is practised only by the wealthier classes and is a waning institution. Excellent agriculturists and gardeners, very laborious, and having a good reputation for honesty, they live on the best terms with their Russian peasant neighbours. The Bashkirs who live between the Kama, Ural and Volga are possibly of Finnish origin, but now speak a Tatar language and have become Mahommedans. (2) The Astrakhan Tatars (about 10,000) are, with the Mongol Kalmucks, all that now remains of the once so powerful Astrakhan empire. They also are agriculturists and gardeners; while some 12,000 Kundrovsk Tatars still continue the nomadic life of their ancestors. (3) The Crimean Tatars, who occupied the Crimea in the 13th century, have preserved the name of their leader, Nogai. During the 15th, 16th and 17th centuries they constituted a rich empire, which prospered until it fell under Turkish rule, when it had to suffer much from the wars fought between Turkey and Russia for the possession of the peninsula. The war of 1853 and the laws of 1860–63 and 1874 caused an exodus of the Crimean Tatars; they abandoned their admirably irrigated fields and gardens and moved to Turkey, so that now their number falls below 100,000. Those of the south coast, mixed with Greeks and Italians, are well known for their skill in gardening, their honesty and their laborious habits, as well as for their fine features, presenting the Tatar type at its best. The mountain Tatars closely resemble those of Caucasus, while those of the steppes—the Nogais—are decidedly of a mixed origin from Turks and Mongols.

The Tatars of Caucasia, who inhabit the upper Kubañ, the steppes of the lower Kuma and the Kura, and the Aras, number about 1,350,000. Of these (4) the Nogais on the Kuma show traces of an intimate mixture with Kalmucks. They are nomads, supporting themselves by cattle-breeding and fishing; few are agriculturists. (5) The Karachais (18,500) in the upper valleys about Elburz live by agriculture. (6) The mountain Tatars (about 850,000), divided into many tribes and of an origin still undetermined, are scattered throughout the provinces of Baku, Erivan, Tiflis, Kutais, Daghestan, and partly also of Batum. They are certainly of a mixed origin, and present a variety of ethnological types, all the more so as all who are neither Armenians nor Russians, nor belong to any distinct Caucasian tribe, are often called Tatars. As a rule they are well built and little behind their Caucasian brethren. They are celebrated for their excellence as gardeners, agriculturists, cattle-tenders and artisans. Although most fervent Shi'ites, they are on very good terms both with their Sunnite and with their Russian neighbours. Polygamy is rare with them, and their women go to work unveiled.

The Siberian Tatars are estimated (1895) at 80,000 of Turki stock and about 40,000 of mixed Finnic stock. They occupy three distinct regions—a strip running west to east from Tobolsk to Tomsk, the Altai and its spurs, and South Yeniseisk. They originated in the agglomerations of Turkish stems which in the region north of the Altai reached some degree of culture between the 4th and the 8th centuries, but were subdued and enslaved by the Mongols. They are difficult to classify, for they are the result of somewhat recent minglings of races and customs, and they are all more or less in process of being assimilated by the Russians, but the following subdivisions may be accepted provisionally. (7) The Baraba Tatars, who take their name from one of their stems (Barama), number about 50,000 in the government of Tobolsk and about 5000 in Tomsk. After a strenuous resistance to Russian conquest, and much suffering at a later period from Kirghiz and Kalmuck raids, they now live by agriculture, either in separate villages or along with Russians. (8) The Cholym or Chulym Tatars on the Cholym and both the rivers Yus speak a Turkish language with many Mongol and Yakut words, and are more like Mongols than Turks. In last century they paid a tribute for 2550 arbaletes, but they now are rapidly becoming fused with Russians. (9) The Abakan or Minusinsk Tatars occupied the steppes on the Abakan and Yus in the 17th century, after the withdrawal of the Kirghizes, and represent a mixture with Kaibals (whom Castrén considers as partly of Ostiak and partly Samoyedic origin) and Beltirs—also of Finnish origin. Their language is also mixed. They are known under the name of Sagais, who numbered 11,720 in 1864, and are the purer Turkish stem of the Minusinsk Tatars, Kaibals, and Kizil or Red Tatars. Formerly Shamanists, they now are, nominally at least, adherents of the Greek Orthodox Church, and support themselves mostly by cattle-breeding. Agriculture is spreading but slowly among them; they still prefer to plunder the stores of bulbs of *Lilium Martagon*, *Paeonia*, and *Erythronium Dens canis* laid up by the steppe mouse (*Mus socialis*). The Soyotes, or Soyons, of the Sayan mountains (estimated at 8000), who are Finns mixed with Turks the Uryankhes of north-west Mongolia, who are of Turkish origin but follow Buddhism, and the Karagasses, also of Turkish origin and much like the Kirghizes, but reduced now to a few hundreds, are akin to the above. (10) The Tatars of the northern slopes of the Altai (nearly 20,000 in number) are of Finnish origin. They comprise some hundreds of Kumandintses, the Lebed Tatars, the Chernevyie or Black-Forest Tatars and the Shors (11,000), descendants of the Kuznetsk or Iron-Smith Tatars. They are chiefly hunters, passionately loving their *taiga*, or wild forests, and have maintained their Shaman religion and tribal organization into *suoks*. They live partly also on cedar-nuts and honey collected in the forests. Their dress is that of their former rulers, the Kalmucks, and their language contains many Mongol words. (11) The Altai Tatars, or "Altaians," comprise—(*a*) the Mountain Kalmucks (12,000), to whom this name has been given by mistake, and who have nothing in common with the Kalmucks except their dress and mode of life, while they speak a Turkish dialect, and (*b*) the Teleutes, or Telenghites (5800), a remainder of a formerly numerous and warlike nation who have migrated from the mountains to the lowlands, where they now live along with Russian peasants. Although Turkestan and Central Asia were formerly known as Independent Tartary, it is not now usual to call the Sarts, Kirghiz and other inhabitants of those countries Tatars, nor is the name usually given to the Yakuts of Eastern Siberia.

It is evident from the above that the name Tatars was originally applied to both the Turkish and Mongol stems which invaded Europe six centuries ago, and gradually extended to the Turkish stems mixed with Mongol or Finnish blood in Siberia. It is used at present in two senses: (*a*) Quite loosely to designate any of the Ural-Altaic tribes, except perhaps Osmanlis, Finns and Magyars, to whom it is not generally applied. Thus some writers talk of the Manchu Tatars. (*b*) In a more restricted sense to designate Mahommedan Turkish-speaking tribes, especially in Russia, who never formed part of the Seljuk or Ottoman Empire, but made independent settlements and remained more or less cut off from the politics and civilization of the rest of the Mahommedan world.

AUTHORITIES.—The literature of the subject is very extensive, and bibliographical indexes may be found in the *Geographical Dictionary* of P. Semenov, appended to the articles devoted respectively to the names given above, as also in the yearly *Indexes* by M. Mezhov and the *Oriental Bibliography* of Lucian Scherman. Besides the well-known works of Castrén, which are a very rich source of information on the subject, Schiefner (St Petersburg academy of science), Donner, Ahlqvist and other explorers of the Ural-Altaians, as also those of the Russian historians Soloviev, Kostomarov, Bestuzhev-Ryumin, Schapov, and Ilovaiskiy, the following containing valuable information may be mentioned: the publications of the Russian Geographical Society and its branches; the Russian *Etnographicheskiy Sbornik;* the *Izvestia* of the Moscow society of the amateurs of natural science; the works of the Russian ethnographical congresses; Kostrov's researches on the Siberian Tatars in the memoirs of the Siberian branch of the geographical society; Radlov's *Reise durch den Altai, Aus Sibirien*; "Picturesque Russia" (*Zhivopisnaya Rossiya*); Semenov's and Potanin's "Supplements" to Ritter's *Asien;* Harkavi's report to the congress at Kazañ; Hartakhai's "Hist. of Crimean Tatars," in *Vyestnik Evropy*, 1866 and 1867; "Katchinsk Tatars," in *Izvestia Russ. Geogr. Soc.*, xx., 1884. Various scattered articles on Tatars will be found in the *Revue orientale pour les Études Oural-Altaïques*, and in the publications of the university of Kazañ. See also E. H. Parker, *A Thousand Years of the Tartars*, 1895 (chiefly a summary of Chinese accounts of the early Turkish and Tatar tribes), and Skrine and Ross, *Heart of Asia* (1899). (P. A. K.; C. El.)

TATE, SIR HENRY, Bart. (1819–1899), English merchant and founder of the National Gallery of British Art, was born at Chorley, Lancashire, in 1819. His father, a minister of religion, put him into business in Liverpool. He became a prosperous sugar-broker, and about 1874 removed to London, where he greatly increased the operations of his firm and made "Tate's Cube Sugar" known all over the world. He had early in his career begun to devote large sums of money to philanthropic and educational purposes. He gave £42,000 to the Liverpool University College, founded in 1881; and a still larger sum to the Liverpool hospitals. Then, when he came to London, he presented four free public libraries to the parish of Lambeth. His interest in art came with later years. He was at first merely a regular buyer of pictures, for which he built a large private gallery in his house at Streatham. Gradually his gallery came to contain one of the best private collections of modern pictures in England, and the owner naturally began to consider what should be done with it after his death. It had always been his intention to leave it to the nation, but in the way of carrying out this generous desire there stood several obstacles. The National Gallery could not have accepted more than a selection from Tate's pictures, which were not all up to the standard of Trafalgar Square; and even when he offered to build a new gallery for them, it was found difficult to secure a suitable site. What Tate offered was to spend £80,000 upon a building if the government would provide the ground; and in 1892 this offer was accepted. A new gallery, controlled by the Trustees of the National Gallery, was built on the site of Millbank Prison. The gallery was opened on 21st July 1897, and a large addition to it was completed just before the donor died. It contained sixty-five pictures presented by him; nearly all the English pictures from the National Gallery painted within the previous eighty years; the pictures purchased by the Royal Academy under the Chantrey Bequest, which had previously hung in South Kensington Museum; and seventeen large works given to the nation by Mr G. F. Watts, R.A. Mr Tate was created a baronet in the year after the Tate Gallery had been opened. He died at Streatham on the 5th of December 1899.

TATE, JAMES (1771–1843), English classical scholar and schoolmaster, was born at Richmond in Yorkshire on the 11th of June 1771. He was educated at Richmond school and Sidney Sussex College, Cambridge (fellow, 1795). From 1796 to 1833 he held the headmastership of his old school, being then appointed canon of St Paul's and vicar of Edmonton. He died on the 2nd of September 1843. The work by which he is chiefly known is his *Horatius Restitutus* (1832).

TATE, NAHUM (1652–1715), English poet laureate and playwright, was born in Dublin in 1652. He was the son of Faithful Teate (as the name was spelt), who wrote a quaint poem on the Trinity entitled *Ter Tria*. Nahum Tate was educated at Trinity College, Dublin, graduating B.A. in 1672. He published a volume of poems in London in 1677, and became a regular writer for the stage. *Brutus of Alba, or The Enchanted Lovers* (1678), a tragedy dealing with Dido and Aeneas, and *The Loyal General* (1680), were followed by a series of adaptations from Elizabethan dramas. In Shakespeare's *Richard II.* he altered the names of the personages, and changed the text so that every scene, to use his own words, was "full of respect to Majesty and the dignity of courts"; but in spite of these precautions *The Sicilian Usurper* (1681) was suppressed on the third representation on account of a possible political interpretation. *King Lear* (1687) was fitted with a happy ending in a marriage between Cordelia and Edgar; and *Coriolanus* became the *Ingratitude of a Commonwealth* (1682). From John Fletcher he adapted *The Island Princess* (1687); from Chapman and Marston's *Eastward Ho* he derived the *Cuckold's Haven* (1685); from John Webster's *White Devil* he took *Injured Love, or The Cruel Husband* (pr. 1707); and Sir Aston Cockayne's *Trappolin suppos'd a Prince* he imitated in *Duke and no Duke* (1685). Tate's name is chiefly connected with these mangled versions of other men's plays and with the famous *New Version of the Psalms of David* (1696), in which he collaborated with Nicholas Brady. A supplement was licensed in 1703. Some of these hymns, notably "While Shepherds watched," and "As pants the hart," rise above the general dull level, and are said to be Tate's work.

Tate was commissioned by Dryden to write the Second Part of *Absalom and Achitophel*. The portraits of Elkanah Settle and Thomas Shadwell, however, are attributed to Dryden, who probably also put the finishing touches to the poem. Of his numerous poems the most original is *Panacea, a poem on Tea* (1700). In spite of his consistent Toryism, he succeeded Shadwell as poet laureate in 1692. He died within the precincts of the Mint, Southwark, where he had taken refuge from his creditors, on the 12th of August 1715.

TATE, RALPH (1840–1901), British geologist, was born at Alnwick in Northumberland in 1840. He was a nephew of George Tate (1805–1871), naturalist and archaeologist, an active member of the Berwickshire Naturalists' Club. He was educated at the Cheltenham Training College and at the Royal School of Mines, and in 1861 he was appointed teacher of natural science at the Philosophical Institution in Belfast. He there studied botany, and published his *Flora Belfastinesis* (1863); and he also investigated the Cretaceous and Liassic rocks of Antrim, bringing his results before the Geological Society of London. In 1864 he was appointed assistant in the museum of that society. In 1867 he went on an exploring expedition to Nicaragua and Venezuela. In 1871 he was appointed to the mining school established by the Cleveland ironmasters first at Darlington and then at Redcar. Here he made a special study of the Lias and its fossils, in conjunction with the Rev. J. F. Blake, and the results were published in an important work, *The Yorkshire Lias* (1876), in which the life-history of the strata was first worked out in detail. In 1875 Tate was appointed professor of natural science in the university of Adelaide, South Australia. He now gave especial attention to the recent and tertiary mollusca of Australia. He was the chief founder of the Royal Society of South Australia, and was in 1893 president of the Australian Association for the Advancement of Science. He died at Adelaide on the 20th of September 1901.

TATI, a district of British South Africa forming, geographically, the S.W. corner of Matabeleland, but attached administratively to the Bechuanaland Protectorate. Area about 2500 sq. m. The railway from Cape Town to Bulawayo crosses the territory with a station at Francistown, the principal settlement. Francistown stands 3254 ft. above the sea and is 126 m. S.W. of Bulawayo by rail. The town of Tati, on the river of that name, is 18 m. S.E. of Shashi river railway station.

Tati owes its importance to the presence of gold, first discovered by the German traveller, Karl Mauch, in 1864. Mining began in 1868, but it was not until 1895 that work on a large scale was undertaken, and it has been frequently interrupted since that date. The chief mine is the Monarch, situated by the railway. A concession to work the gold-mines, and for other purposes, was obtained in 1887 by Mr S. H. Edwards from Lobengula, the Matabele chief, and the mining rights are vested in a company, thereafter formed, called the Tati Concessions Company. (See BECHUANALAND and RHODESIA.)

TATIAN (2nd cent. A.D.), Christian apologist, missionary and heretic. Such knowledge as we have of his life is derived from (1) his own *Oratio ad Graecos* (see § 3); (2) Irenaeus, *Adv. Haereses*, i. 28, i.; (3) Rhodon, quoted in Eusebius's *Hist. Eccl.* v. 13, 1; (4) Clement of Alexandria, *Strom.* i. 1, 11; (5) Eusebius, *Chronicon anno* A.D. 171; (6) Epiphanius, *Panarion*, i. 3, 46. Convenient collections of these passages may be found in E. Schwartz's *Tatiani Oratio ad Graecos, Texte und Untersuchungen*, iv. 1, pp. 51–55; and in A. Harnack's *Geschichte der altchristlichen Litteratur*, i. pp. 485–96. From these data the following outline of his life can be reconstructed. He was a Syrian[1] (Clem. Alex. and Epiphanius) born in Mesopotamia (*Or.* 42) and educated in Greek learning, in which he became proficient (*Or.* i. and 42). He was initiated into the Mysteries, though into which is not stated (*Or.* 29), but after this became acquainted with the Old Testament, and was converted to Christianity. He then went to Rome, where he was a hearer of Justin, and together with the latter incurred the enmity of a certain philosopher Crescens. As this fact is mentioned both in Justin's *Apology* and in Tatian's *Oratio ad Graecos*, and the *Apology* can be dated with fair security about A.D. 152 (see JUSTIN MARTYR), the conversion of Tatian must have been before this date. After the death of Justin he became a heretic—according to Eusebius's *Chronicon* in 173. Among his pupils were Rhodon, and perhaps Apelles (see Victorinus Reat. schol. 44, in *Ep. Hieronymi ad Avitum*, ep. 124) and Clement of Alexandria (*Storm.* i. 1, 11). He made a missionary journey to the East and worked in Cilicia and Pisidia, using the Syrian Antioch as the centre of his efforts (Epiphan.).

According to Epiphanius, Tatian went to the East after the death of Justin (*c.* 165), and then became heretical, and Eusebius states that he was recognized as heretical in 173. Zahn (*Forschungen zur Geschichte des Kanons*, i.) and most writers accept this as in the main correct; it is generally thought that his heresy was recognized in Rome, and it is suggested that this was the reason why he returned to the East. The statement in Epiphanius is capable of being interpreted in this sense, and whereas Tatian was always regarded as heretical in the West, he seems to have been unsuspected in the East. This fact, however, does more than support the suggestion that Tatian's heresy was recognized before he left Rome: it throws some doubt on the theory that after being turned out of the Church in Rome he worked as a missionary in the East without being suspected. Harnack (*Texte und Untersuchungen*, i. 1, pp. 196 ff.) once suggested that the missionary work in the East belongs to an earlier period, and that Tatian left Rome and returned to it between his first arrival and the death of Justin Martyr. But in his *Chronologie*, i. pp. 284 ff., he has withdrawn this, and it is probably too hypothetical; it is, however, the only serious effort to deal with the difficulty, which if not insoluble is at least unsolved.

The Heresy of Tatian.—As in the case of most heresies, we have only the partisan statements of opponents. Everything is therefore open to some doubt, but the following points seem fairly certain. The heresy which Tatian either founded or adopted was that of the Encratites. Their main doctrines were the evil nature of matter, an absolute forbidding of marriage, abstinence from wine and perhaps from meat. It would also seem that Tatian believed in the existence of aeons, one of whom was the Demiurge of the world. He denied the salvation of Adam. It is also stated that in his celebration of the Mysteries (*i.e.* the Eucharist) he used only water (see Tertullian, *De Jejun.* 15; Hippolytus, *Philos.*, 8, 4, 16 and 10, 18; Jerome in *Amos* ii. 12 and Iren., *Adv. Haer.*, i. 28, iii. 23).

Writings.—According to Eusebius, Tatian wrote many books (*Hist. Eccl.*, iv. 29); of these the names of the following have survived:—(1) Περὶ ζῴων (mentioned in *Or.*, 15); (2) Περὶ δαιμόνων (mentioned in *Or.*, 16); (3) Λόγος πρὸς τοὺς Ἕλληνας; (4) Προβλημάτων βιβλίον (Eus., v. 13, 1—a quotation from Rhodon) an attempt to deal with the contradictions to be found in the Bible; (? 5) Πρὸς ἀποφηναμένους τὰ πρὸς θεοῦ (mentioned in *Or.*, 40 as a book which Tatian intended to write, but there is no evidence that he carried his plan into effect; (6) Περὶ τοῦ κατὰ τὸν Σωτῆρα καταρτισμοῦ (Clem. Alex., *Strom.*, iii. 12, 80); (7) The *Diatessaron;* (? 8) a recension of the Pauline epistles (Eus., *Hist. Eccl.*, iv. 29) says that he was accused of producing a μετάφρασις of the epistles so as to smooth the grammar, and in Jerome's preface to St Paul's Epistle to Titus it is stated that he rejected some of the epistles, but not that to Titus. Of these books only two—the *Diatessaron* and the πρὸς τοὺς Ἕλληνας are still extant.

The Λόγος πρὸς τοὺς Ἕλληνας (*Oratio ad Graecos*) belongs to Tatian's Catholic period. He has the double purpose in view of exposing the weakness of the pagan view of the universe and of commending the Christian explanation. For the former purpose he seems to have made use of an already existent book, perhaps the Γοήτων φορά of Oenomaus of Gadara, a Syrian who wrote in the time of Hadrian. The same source seems to have been used by Minucius Felix and Tertullian, and Eusebius in his *Praep. Evan.*, v. 19, quotes some other fragments of the work of Oenomaus. The main argument employed is an exposition of the contradictions, absurdities and immoralities of Greek mythology. A special attack is made on the doctrine of Fate or Necessity. Tatian insists that man is a free agent: that his sins and the consequent evils in the world are the result of free choice, and that the same free choice can remedy the evil.

His positive explanation of the universe is rather difficult to follow. He lays great stress on the Logos doctrine; all good is to be found in union with the Logos; all evil is in matter or in "spirits of a material nature"; the origin of evil in the world seems to be the choice of the latter rather than of the former; and redemption consists in the reverse process. But the choice of evil was not made only by man but by angels, who by their evil choice became the demons, that is, the gods of the heathen world. Both men and angels will be judged at the end of the world, when the good will receive again the immortality which was lost through sin, and the wicked will receive death through punishment with immortality (θάνατον διὰ τιμωρίαν ἐν ἀθανασίᾳ). Tatian does not deny the stories of the Greek mythology—indeed he protests against any attempt to allegorize it—but he insists that these stories are the record of the deeds of demons and have no religious value. The truth of his views he rests, rather strangely, on the argument that Moses, the writer of the Pentateuch, lived long before Homer, whom he regards as the earliest Greek religious writer, and to prove this he quotes a series of synchronisms, which were made use of by

[1] Tatian describes himself as an "Assyrian," and though the terms "Assyrian" and "Syrian" are used very loosely by ancient writers, it is probable that he was born E. of the Tigris, *i.e.* not in Syria as we understand it. Epiphanius, in another passage, calls him an Assyrian.

many subsequent chronologers, including probably Julius Africanus, who in turn was used by Eusebius.

The omissions in the *Oratio* are even more remarkable than its statements. There is at the most not more than an allusion to Christ, who is never mentioned by name, and though there are frequent allusions to the regaining of life, which is accomplished by union with the Logos, there is no reference to the doctrines of the incarnation or of the atonement.

The date of the writing of the *Oratio* cannot be fixed more accurately than that it was before 165 and probably about A.D. 150. On the hypothesis that Tatian remained in Rome until the death of Justin it must have been written there: but on internal evidence Harnack thinks, probably correctly, that it was written in Greece, perhaps in Athens, and Tatian made at least one journey outside Rome before Justin's death (cf. *Texte und Untersuchungen, l.c.*, and *Gesch. d. altchr. Litt., l.c.*). (K. L.)

TATRA MOUNTAINS (Hungarian *Tarczal*) or the High Tatra, the highest group in the central Carpathians, and the central group of the whole Carpathian system. They extend between the rivers Waag, Arva, Dunajec and Poprad, and form a sharply defined and isolated group, rising abruptly like a gigantic wall to an altitude of over 8400 ft. in the midst of a high plateau situated 2600 ft. above sea-level. The Tatra Mountains extend through the Hungarian counties of Liptó and Szepes, and with their northern extremities also through the Austrian crownland of Galicia, and have a length of 40 m. and a width varying between 9 and 15 m. The mean altitude is between 6000 and 7500 ft. The principal peaks are:—the Franz-Josef or Gerlsford (Hung. *Gerlachfalvi-Csúcs*, 8737 ft.), the highest in the Carpathian system; the Lomnitz (*Lomniczi-Csúcs*, 8642 ft.); the Eisthal (*Jégvölgyi-Csúcs*, 8630 ft.); the Tatraspitze or Hohe Visoka (8415 ft.); the Kesmark (8226 ft.); the Meeraugenspitze (*Tengerszem-Csúcs*, 8210 ft.); the Schlagendorf (*Szalóki-Csúcs*, 8050 ft.); and the Kriván (8190 ft.). The principal valleys, which lie at an altitude of 2600 to 3250 ft. above sea-level, and present some of the wildest scenery, are:—the Kohlbach Valley, the Felka Valley, the Valley of Mengsdorf, the Javorina Valley, the Kotlina Valley, in which is the stalactite cavern of Béla, and the Bielka Valley. One of the characteristics of the Tatra are the numerous mountain lakes (112 in number), called by the people "eyes of the sea." The largest of them are the Lake of Csorba, in the southern part of the group, which has an area of 50 acres; the Grosser Fischsee in the Bielka Valley; and the Wielki Staw, with an area of 85 acres, the largest of the Five Polish Lakes, which lie in the Roztoka Valley.

There are many summer resorts in the Tatra Mountains, the most frequented being Tatrafüred (German, *Schmecks*), three small villages situated at an altitude of 3250 ft., at the foot of the Schlagendorf peak; and the environs of the Lake of Csorba, which is called the "Pearl of the Tatra."

TATTA, or THATO, an ancient town of British India, in the Sind province of Bombay, 7 m. from the right bank of the main channel of the Indus and 13 m. from a station on the North-Western railway: pop. (1901) 10,783. Tatta was the capital of the Samma dynasty in Lower Sind in the 16th century, and long continued to be the centre of trade in the country, to which it sometimes gave its name in early European travels. An English factory was established here in 1758, but withdrawn after a few years. There are two old mosques, decorated with the coloured tiles characteristic of Sind.

TATTERSALL'S, the London horse auction mart, founded in 1766 by Richard Tattersall (1724–1795), who had been stud groom to the second duke of Kingston. The first premises occupied were near Hyde Park Corner, in what was then the outskirts of London. Two "Subscription rooms" were reserved for members of the Jockey Club, and they became the rendezvous for sporting and betting men. Among the famous dispersal sales conducted by "Old Tatt" were those of the duke of Kingston's stud in 1774 and of the stud of the Prince of Wales (afterwards George IV.) in 1786. The prince often visited Richard Tattersall, and was joint proprietor with him of the *Morning Post* for several years. He was succeeded by his son, Edmund Tattersall (1758–1810), who extended the business of the firm to France. The third of the dynasty, Richard Tattersall (1785–1859), the eldest of Edmund's three sons, became head of the firm at his father's death. He had his grandfather's ability and tact, and was the intimate of the best sporting men of his time. Another Richard Tattersall (1812–1870), son of the last, then took command of the business. His great-grandfather's 99-year lease having expired, he moved the business to Knightsbridge. Richard was followed by his cousin, Edmund Tattersall (1816–1898), and he by his eldest son, Edmund Somerville Tattersall (b. 1863).

A son of the second Richard Tattersall, George Tattersall (1817–1849), was a well-known sporting artist. In 1836 he compiled a guide to *The Lakes of England* illustrated with forty-three charming line drawings, and he showed skill as an architect by building the Tattersall stud stables at Willesden. His experience in this and similar undertakings led him to publish *Sporting Architecture* (1841). In the same year, under the pseudonym "Wildrake," he published *Cracks of the Day*, describing and illustrating sixty-five race-horses. He also contributed illustrations to the *Hunting Reminiscences* of Nimrod (Charles J. Apperley), the *Book of Sports* (1843), and the *New Sporting Almanack*.

TATTNALL, JOSIAH (1795–1871), American naval officer, was born near Savannah, and was educated in England. He entered the United States navy in 1812, and was actively employed till the beginning of the Civil War. He may be said to have gained a world-wide reputation by his use of the phrase "blood is thicker than water" to justify his intervention on behalf of the British squadron engaged in the operations against the Peiho Forts. Tattnall's flagship the *Toeywan* had grounded shortly before, and had been helped off by the British squadron. He was in the Peiho river when the unsuccessful attack of the 25th of June 1859 was made. Tattnall not only brought the *Toeywan* under fire, but lent the aid of his boats to land detachments to turn the Chinese defences. When the Civil War began he took the side of the Confederacy. He was put in command of its naval forces when Franklin Buchanan resigned after he was wounded in the action with the Federal squadron in Hampton Roads. The Confederate States were never able to form a sea-going squadron, and Tattnall had no chance to do more than make a struggle with insufficient resources on its rivers. He died on the 14th of June 1871.

TATTOO, a signal given by beat of drum and call of bugle at nightfall for soldiers to go to quarters when in garrison or to tents when in the field. The earlier word is *taptoo* or *taptow*, and was borrowed from Du. *taptoe;* the phrase *de taptoe slaan*, to close the taps, and the parallel Ger. *Zapfenstreich*, literally "tap-stroke" (*Zapf*, a tap of a cask), show that it meant originally a signal that the "taps" or public-houses were closed for the night.

TATTOOING (Tahitian, *tatu*, from *ta*, mark), the practice of decorating the skin, by cutting or puncturing, with various patterns into which a colouring matter is introduced. Though the word is Polynesian, the custom appears to have been almost universal, but tends to disappear before the spread of civilization. The prohibition to the Jews (Lev. xix. 28) under the Mosaic Law to "print any marks" upon themselves is believed to have reference to tattooing, which is still common in Arabia. The North and South American Indians, the Chinese, Japanese, Burmese, all tattoo. The origin of the custom is disputed. It was probably at first for purely ornamental purposes and with the idea of attracting the opposite sex. The discovery in the caves of Western Europe of hollowed stones which had been apparently used for grinding up ochre and other coloured clays is thought evidence that prehistoric man painted himself, and tattooing for decorative reasons may easily date back to the cave-dwellers. The modern savage paints himself as a protection against cold, against the bites of insects or the sun's rays, and most of all to give himself a ferocious appearance in battle, as Caesar relates of the ancient Britons. Any of these motives may have shared in originating tattooing. Subsequently the practice assumed religious and social significance, varying with the country and according to the age at which it was performed. Thus in Polynesia it is begun in or about the twelfth year, and becomes thus a mark of puberty; while among the Arabs and the Kabyles of Algeria infants are tattooed by their mothers for simple ornament or as a means of recognizing them. The American Indians bore from their initiation at puberty the mark of the personal or tribal *totem*, which at once represented the religious side of their life, and served the practical purpose of enabling them to be known by friendly tribes. Among the Australians tattooing served as a mark of adoption into the family or tribe, the distinctive emblem or *kobong* being scarred on the thighs.

Tattooing is regarded, too, as a mark of courage. A Kaffir who has been a successful warrior has the privilege of making a long incision in his thigh, which is rubbed with cinders until sufficiently discoloured. Elsewhere tattooing is a sign of mourning, deep and numerous cuts being made on face, breast and limbs. Among the Fijians and Eskimos the untattooed were regarded as risking their happiness in the future world. Some of the most remarkable examples of tattooing are those to be found among the Laos, whose stomachs, thighs, legs and breasts are often completely covered with fantastic animal figures like those on Buddhistic monuments.

The rudest form of tattooing is that practised specially by the Australians and some tribes of negroes. It consists in cutting gashes, arranged in patterns, on the skin and filling the wounds with clay so as to form raised scars. This tattooing by scarring as compared with the more common mode of pricking is, as a general rule, confined to the black races. Light-skinned races tattoo, while dark practise scarring. In Polynesia the art of tattooing reached its highest perfection. In the Marquesas group of islands, for example, the men were tattooed all over, even to the fingers and toes and crown of the head, and as each operation took from three to six months, beginning at virility, a man must have been nearly thirty before his body was completely covered. In New Zealand the face was the part most tattooed, and Maori heads so decorated were at one time in much request for European museums, but they are no longer obtainable in the colony. In Japan, where it became a high art, tattooing was neither ceremonial nor symbolical. It was in lieu of clothing, and only on those parts of the body usually covered in civilized countries, and in the case of those only who, like the jinrikisha-men, work half naked. The colours used are black, which appears blue, made from Indian ink, and different tints of red obtained from cinnabar. Fine sewing-needles, eight, twelve, twenty or more, fixed together in a piece of wood, are used. A clever tattooer can cover the stomach or back in a day. As soon as the picture is complete, the patient is bathed in hot water. The Ainus, on the other hand, tattoo only the exposed parts of the body, the women, unlike the Japanese, being frequently patients. The tattooing instruments used in Polynesia consisted of pieces of sharpened bone fastened into a handle, with their edges cut into teeth. These were dipped into a solution of charcoal and then driven into the skin by smart blows with a mallet. During the operation, assistants, usually female relatives, drowned the cries of the sufferer with songs and the beating of drums.

Under the influence of civilization tattooing is losing its ethnological character, and has become, in Europe at least, an eccentricity of soldiers and sailors and of many among the lower and often criminal classes of the great cities. Among eight hundred convicted French soldiers Lacassagne found 40 per cent. tattooed. In the British army till 1879 the letters D. and B. C. for *Deserter* and *Bad Character* were tattooed with needles and Indian ink; and tattooing has often been used to identify criminals and slaves.

See Lacassagne, *Les Tatouages* (Paris, 1881); General Robley, *Moko or Maori Tattooing* (1896).

TAUCHNITZ, the name of a family of German printers and publishers. Karl Christoph Traugott Tauchnitz (1761–1836), born at Grossbardau near Grimma, Saxony, established a printing business in Leipzig in 1796 and a publishing house in 1798. He specialized on the publication of dictionaries, Bibles and stereotyped editions of the Greek and Roman classics. The business was carried on by his son, Karl Christian Phillipp Tauchnitz (1798–1884), until 1865, when the business was sold to O. Holtze. He left large sums to the city of Leipzig for philanthropic purposes. Christian Bernhard, Freiherr von Tauchnitz (1816–1895), the founder of the existing firm of Bernhard Tauchnitz, was the nephew of the first-mentioned. His printing and publishing firm was started at Leipzig in 1837. The Library of British and American Authors, so familiar to travellers on the continent of Europe, was begun in 1841. In 1908 the collection numbered over 4000 volumes. In 1868 he began the Collection of German Authors, followed in 1886 by the Students' Tauchnitz editions. In 1860 he was ennobled with the title of *Freiherr* (Baron), and in 1877 was made a life member of the Saxon Upper Chamber. From 1866 to 1895 he was British Consul-General for the kingdom and duchies of Saxony. He was succeeded in the business by his son, Christian Karl Bernhard, Freiherr von Tauchnitz.

TAULANTII, in ancient geography, an Illyrian people in the neighbourhood of Epidamnus (Thuc. i. 24). They were originally powerful and independent, under their own kings. One of these was Glaucias, who fought against Alexander the Great, and placed Pyrrhus, the infant king of Epirus, whom he had refused to surrender to Cassander, upon the throne (Plutarch, *Pyrrhus*, 3). Later the Taulantii fell under the sway of the kings of Illyria, and when the Romans were carrying on war against the Illyrian queen, Teuta, they were unimportant.

TAULER, JOHANN (*c.* 1300–1361), German mystic, was born about the year 1300 in Strassburg, and was educated at the Dominican convent in that city, where Meister Eckhart, who greatly influenced him, was professor of theology (1312–1320) in the monastery school. From Strassburg he went to the Dominican college of Cologne, and perhaps to St James's College, Paris, ultimately returning to Strassburg. In 1324 Strassburg with other cities was placed under a papal interdict. Legend says that Tauler nevertheless continued to perform religious services for the people, but though there may be a germ of historical truth in this story, it is probably due to the desire of the 16th-century Reformers to enroll the famous preachers of the middle ages among their forerunners. In 1338–1339 Tauler was in Basel, then the headquarters of the "Friends of God" (see MYSTICISM), and was brought into intimate relations with the members of that pious mystical fellowship. Strassburg, however, remained his headquarters. The Black Death came to that city in 1348, and it is said that, when the city was deserted by all who could leave it, Tauler remained at his post, encouraging by sermons and personal visitations his terror-stricken fellow-citizens. His correspondence with distinguished members of the *Gottesfreunde*, especially with Margaretha Ebner, and the fame of his preaching and other work in Strassburg, had made him known throughout a wide circle. He died on the 16th of June 1361.

The well-known story of Tauler's conversion and discipline by "the Friend of God from the Oberland" (see NICHOLAS OF BASEL) cannot be regarded as historical. Tauler's sermons are among the noblest in the German language. They are not so emotional as Suso's, nor so speculative as Eckhart's, but they are intensely practical, and touch on all sides the deeper problems of the moral and spiritual life.

Tauler's sermons were printed first at Leipzig in 1498, and reprinted with additions from Eckhart and others at Basel (1522) and at Cologne (1543). There is a modern edition by Julius Hamberger (Frankfort, 1864), and R. H. Hutton published Tauler's Sermons for Festivals under the title of *The Inner Way*. See Denifle, *Das Buch von geistlicher Armuth* (Strassburg, 1877); Carl Schmidt, *Johann Tauler von Strassburg* (Hamburg, 1841); S. Winkworth, *Tauler's Life and Sermons* (London, 1857); R. A. Vaughan, *Hours with the Mystics*, 3rd ed., vol. i. pp. 214–307; Preger's *Gesch. der deutschen Mystik im Mittelalter*, vol. iii.; W. R. Inge, *Christian Mysticism*; R. M. Jones, *Studies in Mystical Religion* (1909).

TAUNG-GYI, the headquarters of the superintendent and political officer, southern Shan States, Burma. It is situated in 96° 58′ E. and 20° 47′ N., at an altitude of about 5000 ft., in a depressed plateau on the crest of the Sintaung hills. It is in the state of Yawnghwe, 105 m. from Thazi railway station on the Rangoon-Mandalay railway, with which it is connected by a cart-road. The civil station dates from 1894, when there were only a few Taungthu huts on the site. There were in 1906 upwards of a thousand houses, many of them substantially built of brick. Since 1906 the southern Shan States have been garrisoned by military police, whose headquarters are in Taunggyi. The station is to a considerable extent a commercial depôt for the country behind, and there are many universal supply shops of most nationalities (except British)—Austrian, Chinese and Indian. The five-day bazaar is the trading place of the natives of the country. A special quarter contains the temporary residences of the chiefs when they visit headquarters, and there is a school for their sons. An orchard for experimental cultivation has met with considerable success. The average shade maximum temperature is 84°; the minimum 39°.

TAUNTON, HENRY LABOUCHERE, Baron (1798–1869), English politician, came of a French Huguenot family, which, on leaving France, settled in Holland. His father, Peter Caesar Labouchere, merchant, was a partner in the wealthy Amsterdam banking firm of Hope & Company;[1] he went to live in England, and married a daughter of Sir Francis Baring. Henry was his elder son, while a younger son, John, was the father of the later well-known Radical member of parliament and proprietor of *Truth*, Henry Labouchere (b. 1831). He was educated at Winchester and Christ Church, Oxford, and entered the House of Commons as a Whig in 1826. From 1830 to 1858 he sat for Taunton, Somerset. After filling various minor offices, he became president of the Board of Trade in 1839–41; and in 1846 he was chief secretary for Ireland. In 1847–52 he was again president of the Board of Trade, and from 1855 to 1858 secretary of state for the colonies. In 1859 he was created Baron Taunton, but on his death, on the 13th of July 1869, the title became extinct.

TAUNTON, a municipal and parliamentary borough and market town of Somersetshire, England, on the river Tone, 163 m. W. by S. of London by the Great Western railway. Pop. (1901) 21,087. Standing in the beautiful valley of Taunton Dene, the town is chiefly built on the south side of the river. Its three main streets, broad and regular, converge upon a triangular space called the Parade, where there is a market cross. The parish church of St Mary Magdalene is one of the finest and largest Perpendicular churches in England. Remnants of Norman work are preserved in the chancel arch, and of Early English work in the north aisles and transepts. The tower, noteworthy for its union of elaborate ornament and lightness of effect, exceeds 150 ft. in height. There are double aisles on each side of the nave, and the whole interior is admirable in its harmony of design and colour. Little is left of an Austin priory established in the reign of Henry I. by William Giffard, bishop of Winchester, who also built the castle, now a museum for prehistoric, Roman and medieval antiquities. Taunton castle, though largely rebuilt in 1496, embodies the remains of a very early fortress, while its walls and keep date from the 12th century, its towers and gatehouses from the 13th or 14th. At the Restoration it was dismantled and its moat filled in. Among the schools is a grammar school founded in 1522 by Richard Fox, bishop of Winchester. There are also public gardens, assembly rooms, almshouses, a town hall, market hall, a hospital founded in 1819 to commemorate the jubilee of George III., and a shire hall containing a series of marble busts representing, among other Somerset worthies, Admiral Blake, John Locke the philosopher, the Puritan leader Pym, Bishop Ken, and Speke the African explorer. The local industries are silk, linen and glove manufactures, iron and brass founding, coachbuilding, cabinetmaking, malting and brewing; while Taunton Dene is famous as a rich agricultural district.

[1] The Amsterdam Hopes were descended from Henry Hope, son of a Scottish merchant, and younger brother of Sir Thomas Hope (d. 1646), the famous Scottish lord-advocate, ancestor of the earls of Hopetoun (marquess of Linlithgow, *q.v.*). Among his descendants was Thomas Hope (1770–1831), father of A. J. B. Beresford-Hope (1820–1887), politician and author.

The parliamentary borough of Taunton returns one member. The town is governed by a mayor, six aldermen and eighteen councillors. Area, 1393 acres.

There was perhaps a Romano-British village near the suburb of Holway, and Taunton (Tantun, Tantone, Tauntone) was a place of considerable importance in Saxon times. King Ine threw up an earthen castle here about 700, and a monastery was founded before 904. The bishops of Winchester owned the manor, and obtained the first charter for their "men of Taunton" from King Edward in 904, freeing them from all royal and county tribute. At some time before the Domesday Survey Taunton had become a borough with very considerable privileges, governed by a portreeve appointed by the bishops. It did not obtain a charter of incorporation until that of 1627, which was renewed in 1677. The corporation existed until 1792, when the charter lapsed owing to vacancies in the number of the corporate body, and Taunton was not reincorporated until 1877. Parliamentary representation began in 1299, and two members were returned until 1885. A fair on the 7th of July was held under a charter of 1256, and there are now two fairs yearly, on the 17th of June and the 7th of July. The Saturday market for the sale of corn, cattle and provisions dates from before the Conquest. There is also a smaller market on Wednesdays. The medieval fairs and markets of Taunton were celebrated for the sale of woollen cloth called "Tauntons" made in the town. On the decline of the west of England woollen industry, silk-weaving was introduced at the end of the 18th century.

See *Victoria County History, Somerset*; Toulmen's *History of Taunton*, edited by James Savage (1830).

TAUNTON, a city and one of the county-seats of Bristol county, Massachusetts, U.S.A., at the head of ocean navigation on the Taunton river, 17 m. above its mouth, about 35 m. S. of Boston, and about 14 m. N. of Fall River. Pop. (1890) 25,448; (1900) 31,036, of whom 9140 were foreign-born, 2844 being Irish, 2366 French-Canadians, 1144 English, and 801 English-Canadians; (1910, U.S. census) 34,259. Taunton is served by the New York, New Haven & Hartford railroad (Old Colony Branch) and by interurban electric railways connecting with Fall River, New Bedford, Providence and Boston. The channel of the Taunton river has been deepened and widened by the Federal government, and in 1910 vessels of 11 ft. draft could reach the city at high water (mean range of tide at Taunton, 3·4 ft.). Within the corporate limits of the city, which has a land area of 44·25 sq. m., there are six villages—Hopewell, Britanniaville, Oakland, Whittenton, East Taunton and the Weir. Taunton Green, a rectangular stretch of land fringed with lofty elms, the "common" of the New England town, about which is the business portion of the modern city, is 1 m. from the Weir, the port of the city.

The city contains interesting specimens of colonial or early 19th-century architecture. Among the modern public buildings are the handsome granite County Court House (1895), facing the Green, the Public Library building (given by Andrew Carnegie), the registry building, the county gaol, the city hall, the post office, an old ladies' home, an emergency hospital, the Morton Hospital, occupying the fine old residence of Governor Marcus Morton, and the Y.M.C.A. building. The Bristol County Law Library and Old Colony Historical Society (incorporated in 1853 and organized in 1854) possess valuable collections of books, and the latter has a collection of portraits and antiquities. Bristol Academy (1792; non-sectarian) is a well-known preparatory school, and there is also a commercial school—the Bristol County Business College. At Norton (pop. in 1910, 2544), directly N. of Taunton, and formerly within its boundaries, is Wheaton Seminary (1834) for girls. Among social clubs are the Winthrop Club, the Bristol Club, the Taunton Boat Club, the Yacht Club, and the Country Club. A good water-supply, owned by the city, is obtained from neighbouring lakes and ponds, along the shores of which are many summer cottages. Taunton was one of the first cities in the United States to own and operate its own electric lighting plant, which it acquired from a private corporation in 1897. Its industrial importance began with the establishment of ironworks in 1656; the plant then opened continued in active operation for about 225 years. Brick-making and shipbuilding were two of the early industries; the latter, formerly very important, has now been abandoned. The manufactures to-day are extensive and varied. The aggregate value of the factory product in 1905 was $13,644,586, an increase of 18·2 per cent. over that of 1900. Of this amount the value of the cotton manufactured was $6,141,598, or 45 per cent. of the whole. Herring fisheries give occupation during a part of the year to a considerable number of workers. Taunton has a prosperous jobbing trade, and large shipping interests, the coastwise trade being particularly important.

Taunton was founded in 1638, when the territory was purchased from Massasoit by settlers from the Massachusetts Bay Colony, and became the frontier town of Plymouth Colony. Myles Standish was engaged on the original survey. But there had been earlier settlers in the region—at "Tecticutt" (Titicut), which later became part of Taunton. The settlement at Taunton was at first known as Cohannet, but the present name—from Taunton, Somerset, England, the home of many of the settlers—was soon adopted. The town was incorporated in 1639. In 1671 it was the scene of a meeting between Gov. Thomas Prince and King Philip, at which a treaty was drawn up. During King Philip's War, Taunton was a base of operations for Plymouth Colony troops under Gov. Josiah Winslow. In 1686 Taunton was one of the towns which refused to comply with Sir Edmund Andros's demands for a tax levy. For some years Thomas Coram, the philanthropist and founder of the London Foundling Hospital, was engaged in the shipbuilding industry here. In 1774, after the passage of the Boston Port Bill, the people of Taunton showed their sympathy for Boston by raising on the Green a red flag on which were inscribed the words "Liberty and Union." The leader of the patriotic party at this time was Robert Treat Paine, to whose memory a bronze statue has been erected. During Shays's rebellion the Taunton court-house was twice besieged by insurgents, who were each time dispersed through the resolute action and firmness of Gen. David Cobb, one of the judges. The event is commemorated by a tablet on Taunton Green. In Berkley, which until 1735 was a part of Dighton (Taunton South Purchase, separated from Taunton in 1712), is the famous Dighton Rock, with inscriptions long erroneously supposed to have been made by Norse discoverers of America, but now known to be the work of Indians. Taunton was chartered as a city in 1864. In 1909 a new city charter was adopted, under which the mayor and nine councilmen (elected at large) were the only city officers elected at any city election; candidates for these offices are nominated by petition; the mayor appoints, subject to the approval of the council, a chief of police and a city solicitor.

See S. H. Emery, *History of Taunton from its Settlement to the Present Time* (Syracuse, N.Y., 1893); D. H. Hurd, *History of Bristol County* (Philadelphia, 1883); *Quarter Millennial Celebration* (Taunton, 1889).

TAUNUS, a wooded mountain range of Germany in the Prussian province of Hesse-Nassau and the grand-duchy of Hesse-Darmstadt. It lies between the Rhine and the Main on the S. and the Lahn on the N., and stretches some 55 m. E. and W. Its southern slopes stand 5 to 10 m. back from the Main, but leave only a very narrow strip of low ground alongside the Rhine, and from Bingen downwards they overhang it with precipitous crags, many of which are crowned with picturesque ruins. It has an average elevation of 1500 ft. The loftiest peaks occur in the east, where the imposing cluster of Grosser Feldberg (2887 ft.), Kleiner Feldberg (2714 ft.) and Altkönig (2618 ft.) dominate the Wetterau and the valley of the Main. Above the Rheingau, or the slopes which stretch down to the Rhine between Biebrich and Bingen, the altitude averages 1500 to 1700 ft. The geological core of the system consists of primitive argillaceous schists, capped by quartzite and broken through in places by basalt. On the northern side, which sinks on the whole gently towards the Lahn, the greywacke formation attains a considerable development. The hills are almost everywhere well wooded, the predominant trees being firs and beeches. The lower slopes are, wherever possible, planted with vineyards, orchards and chestnut and almond groves. The vineyards of the Rheingau are specially famous, and yield brands of wine—*e.g.* Johannisberger, Steinberger, Rüdesheimer, Marcobrunner, Hochheimer, Rauenthaler, Assmannshäuser, and others—which enjoy the highest reputation amongst the vintages of Germany. The Taunus is also famous for the number and efficacy of its mineral springs, which annually attract thousands of visitors to the celebrated spas of Wiesbaden, Homburg, Ems, Schlangenbad, Schwalbach, Soden and Nauheim, while the waters of Selters and other springs are exported in large quantity. The sheltered position and warm climate have led also to the establishment of the health resorts of Falkenstein (1875) and Schmitten, and of tourist centres at Königstein, Cronberg and Ober Ursel.

Above Falkenstein stand the ruins of the ancestral castle of Kuno, the powerful archbishop of Trier; above Königstein are the remains of a fortress of like name, formerly belonging to the electors of Mainz, and destroyed by the French in 1796; on Altkönig are two concentric lines of pre-Roman fortifications, 4557 and 2982 ft. in circumference. Interest also attaches to the once celebrated Cistercian abbey of Eberbach, founded in 1116; to Eltville, a favourite residence of the archbishops of Mainz in the 14th and 15th centuries; and to the family seats of Eppstein, Katzenelnbogen and Scharfenstein.

The chief historical monument of this region is the Saalburg, an ancient Roman fort serving as a centre of communications along the *limes* or fortified frontier-line drawn from Rhine to Main by Domitian (see Limes Germanicus). The excavations, which were begun in 1868, have revealed four different encampments, the earliest of which perhaps dates back to the time of the earliest Roman conquest. The remains now visible are an excellent type of the solidly constructed permanent camps of the middle imperial period (about A.D. 200). Elaborate restorations have been undertaken, and the minor remains have been housed since 1904 in the reconstructed *praetorium* or headquarters. An electric tram connects the Saalburg with Homburg (distance 4 m.).

Forty miles to the west of the Saalburg there is a modern national monument, the colossal figure of Germania, which stands on a bold spur of the Taunus 740 ft. above the Rhine. It was erected in 1883 to commemorate the War of 1870–71 and the re-creation of the German empire in the latter year. The steep crags of the western end of the Taunus, where they abut upon the Rhine, are rich in the romantic associations of the great river. Here are the rock of the siren Lurlei or Lorelei; the old castles of Stahleck and Pfalz, which belonged to the Counts Palatine of the Rhine; and the quaint medieval towns of Caub and St Goarshausen. Schloss Friedrichshof, at the foot of the Feldberg and Altkönig, immediately north of Kronberg, was built in 1889–97 by the widowed empress Frederick, and is the place where she died in 1901. The railway from Frankfort-on-Main to Oberlahnstein skirts the south and west foot of the range, that from Frankfort to Cassel the eastern side, while the line from Wiesbaden and Höchst to Limburg intersects it from south to north.

See *Die Heilquellen des Taunus* (published by Grossmann, Wiesbaden, 1887); Sievers, *Zur Kenntnis des Taunus* (Stuttgart, 1891), and the *Taunus Club's Guide* (4th ed. Frankfort-on-Main, 1905). For the Saalburg see L. Jacobi, *Das Römerkastell Saalburg* (2 vols., Homburg, 1897); also a small guide by the same author (3rd ed. Homburg, 1907).

TAUPO, a township of East Taupo county, New Zealand, in the south-west of the Hot Spring district of North Island. It attracts many visitors both as a health resort and on account of the magnificent scenery and remarkable volcanic phenomena of the surrounding district. It lies on the north-east shore of lake Taupo, the largest lake in the island, having an extreme length of 26 m. and a shore-line, not counting minor indentations, of about 100 m., and lying 1200 ft. above sea-level. The river Waikato, which reaches the west coast not far from Manukau Harbour near Auckland, here leaves the lake. The district abounds in geysers, springs, mud volcanoes and other phenomena; some of the waters have petrifying powers, and some of the springs are vividly coloured. On the road running N.E. to Rotorua (56 m.) are the resorts of Weirakei (7 m.) and Ateamuri (31 m.). Lake Taupo is finely situated, hills rising over 2000 ft. immediately from the shores, while the mountains of Tongariro, Ngauruhoe, an active volcano, and Ruapehu, a snow-clad peak, back the view to the south and mark the limit of the great volcanic line which extends 160 m. north-westward to White Island in the Bay of Plenty. The upper Waikato enters the lake from the south near Tokaano, where there is another collection of springs, &c. The river forms several fine falls and rapids below the lake.

TAURELLUS, NICOLAUS (1547–1606), German philosopher and theologian, was born at Mömpelgard. He read theology at Tübingen and medicine at Basel, where he lectured on physical science. He subsequently became professor of medicine at Altdorf, where he died in 1606. He attacked the dominant Aristotelianism of the time, and endeavoured to construct a philosophy which should harmonize faith and knowledge, and bridge over the chasm made by the first Renaissance writers who followed Pomponazzi. Scholasticism he condemned on account of its unquestioning submission to Aristotle. Taurellus maintained the necessity of going back to Christianity itself, as at once the superstructure and the justification of philosophy.

His chief works were *Philosophiae Triumphus* (1573); *Synopsis Metaphysicae Aristotelis* (1596); *De Rerum Aeternitate* (1604); and a treatise written in criticism of Caesalpinus entitled *Caesae Alpes* (1597). See Schmid-Schwarzenburg, *Nicolaus Taurellus* (1860 and 1864).

TAURI, the earliest known inhabitants of the mountainous south coast of the Crimea (Herodotus iv. 103). Nothing is certain as to their affinities. They probably represent an old population perhaps connected with some Caucasus stock; in spite of the resemblance of the name Taurisci they are not likely to be Celts. They were famous in the ancient world for their maiden goddess, identified by the Greeks with Artemis Tauropolos or Iphigeneia, whom the goddess was said to have brought to her shrine at the moment when she was to have been sacrificed at Aulis. Orestes sought his sister, and almost fell a victim to the Tauric custom of sacrificing to the maiden shipwrecked strangers, a real custom which was the ground of the whole myth. His adventures were the subject of plays by Euripides and Goethe. Towards the end of the 2nd century B.C. we find the Tauri dependent allies of the Scythian king Scilurus, who from their harbour of Symbolon Portus or Palacium (Balaclava) harassed Chersonese (*q.v.*). Their later history is unknown. (E. H. M.)

TAURIDA, a government of southern Russia, including the peninsula of Crimea and a tract of mainland situated between the lower Dnieper and the coasts of the Black Sea and the Sea of Azov. It is bounded by these two seas on the S., while it has on the N. the governments of Kherson and Ekaterinoslav. The area is 24,532 sq. m., of which 9704 sq. m. belong to the Crimea. The continental part consists of a gently undulating steppe (from sea-level up to 400 ft. in the north-east) of black earth, with only a few patches of saline clay on the shores of the Sivash or Putrid Sea, and sand along the lower Dnieper. The government is drained by the Dnieper, which flows along the frontier for 180 m., and by two minor streams, the Molochnaya and Berda. Many small lakes and ponds occur in the north, as well as on the Kinburn peninsula, at the mouth of the Dnieper, where salt is made. There are no forests. The climate is continental, and resembles that of central Crimea and Kherson. The population in 1906 was estimated at 1,634,700. The continental portion, although less mixed than that of the peninsula, consists of Great and Little Russians, who constitute 83 per cent. of the whole, Germans (5·4 per cent.), Bulgarians (2·8 per cent.), Jews (3·8 per cent.), and Armenians. The chief occupation of the people is agriculture, and every available patch of land has been brought under the plough. In 1900 no less than 43 per cent. of its area was under cereal crops alone. The principal crops are rye, wheat, oats, barley and potatoes. Tobacco is also grown, and over 32,000 acres are under vineyards, while gardens extend to some 15,500 acres in Crimea. Live-stock breeding is extensively engaged in. Salt is the only mineral raised, but the iron industry, and especially the manufacture of agricultural machinery (*e.g.* at Berdyansk), has greatly developed. The export trade is considerable, the chief ports being Sevastopol, Eupatoria, Theodosia, and Yalta on the Black Sea, and Azov and Berdyansk on the Sea of Azov. The fisheries along the coast are active. Manufactures are insignificant, but there is a brisk export trade in grain, salt, fish, wool and tallow. The government is divided into eight districts, the chief towns of which are Simferopol, capital of the government, Eupatoria and Theodosia, in Crimea, and Aleshki, Berdyansk, Melitopol, Perekop and Yalta on the continent.

TAURINI, an ancient Ligurian people, although the name may be of Celtic origin, who occupied the upper valley of the Padus (Po) in the centre of the modern Piedmont. In 218 B.C. they were attacked by Hannibal, with whose friends the Insubres they had a long-standing feud, and their chief town (Taurasia) was captured after a three days' siege (Polybius iii. 60, 8). As a people they are rarely mentioned in history. It is not known when they definitely became subject to the Romans, nor when the colony of (Julia) Augusta Taurinorum (Torino, Turin) was founded in their territory (probably by Augustus after the battle of Actium). Both Livy (v. 34) and Strabo (iv. p. 209) speak of the country of the Taurini as including one of the passes of the Alps, which points to a wider use of the name in earlier times.

See H. Nissen, *Italische Landeskunde*, ii. (1902), p. 163; and ancient authorities quoted in A. Holder, *Altceltischer Sprachschatz*, ii. (1904).

TAUROBOLIUM, the sacrifice of a bull, usually in connexion with the worship of the Great Mother of the Gods, though not limited to it. Of oriental origin, its first known performance in Italy occurred in A.D. 134, at Puteoli, in honour of Venus Caelestis. Prudentius describes it in *Peristephanon* (x., 1066 ff.): the priest of the Mother, clad in a toga worn *cinctû Gabino*, with golden crown and fillets on his head, takes his place in a trench covered by a platform of planks pierced with fine holes, on which a bull, magnificent with flowers and gold, is slain. The blood rains through the platform on to the priest below, who receives it on his face, and even on his tongue and palate, and after the baptism presents himself before his fellow-worshippers purified and regenerated, and receives their salutations and reverence.

The taurobolium in the 2nd and 3rd centuries was usually performed as a measure for the welfare of the Emperor, Empire, or community, its date frequently being the 24th of March, the *Dies Sanguinis* of the annual festival of the Great Mother and Attis. In the late 3rd and the 4th centuries its usual motive was the purification or regeneration of an individual, who was spoken of as *renatus in aeternum*, reborn for eternity, in consequence of the ceremony (*Corp. Insc. Lat.* vi. 510–512). When its efficacy was not eternal, its effect was considered to endure for twenty years. It was also performed as the fulfilment of a vow, or by command of the goddess herself, and the privilege was limited to no sex nor class. The place of its performance at Rome was near the site of St Peter's, in the excavations of which several altars and inscriptions commemorative of taurobolia were discovered.

The taurobolium was probably a sacred drama symbolizing the relations of the Mother and Attis (*q.v.*). The descent of the priest into the sacrificial foss symbolized the death of Attis, the withering of the vegetation of Mother Earth; his bath of blood and emergence the restoration of Attis, the rebirth of vegetation. The ceremony may be the spiritualized descent of the primitive oriental practice of drinking or being baptized in the blood of an animal, based upon a belief that the strength of brute creation could be acquired by consumption of its substance or contact with its blood. In spite of the phrase *renatus in aeternum*, there is no reason to suppose that the ceremony was in any way borrowed from Christianity.

(G. SN.)

TAURUS ("the Bull"), in astronomy, the second sign of the zodiac (*q.v.*), denoted by the symbol ♉. It is also a constellation of very great antiquity, the Pleiades and Hyades, two star clusters, being possibly referred to in the Old Testament; Aldebaran, a star, is mentioned by Hesiod and Homer. Ptolemy catalogued 44 stars, Tycho Brahe 43, Hevelius 51. The Greeks fabled this constellation to be the bull which bore Europa across the seas to Crete, and was afterwards raised to the heavens by Jupiter. *α Tauri*, or Aldebaran, is a brilliant star of a reddish colour and magnitude 1·2; this star is the principal object of the group named the Hyades, named after the seven daughters of Atlas and Aethra—Ambrosia, Coronis, Eudora, Pasithoë, Plexaris, Pytho and Tycho—fabled by the Greeks to have been transformed into stars by Jupiter for bewailing the death of their brother Hyas. Another star group in this constellation is the Pleiades. *λ Tauri* is an "Algol" variable, varying in magnitude from 3·4 to 4·2. Nebula *M*.1 *Tauri* is a famous "crab" nebula, so named by Lord Rosse from its clawlike protuberances; it is the first of the series of nebula on the enumeration of Messier.

TAUSEN, HANS (1494–1561), the protagonist of the Danish Reformation, was born at Birkende in Funen in 1494. The quick-witted peasant lad ran away from the plough at an early age, finally settling down as a friar in the Johannite cloister of Antvorskov near Slagelse. After studying at Rostock and teaching there for a time and also at Copenhagen, he was again sent abroad by his prior, visiting, among other places, the newly founded university of Leyden and making the acquaintance of the Dutch humanists. He was already a good linguist, understanding both Latin and Hebrew. Subsequently he translated the books of Moses from the original. In May 1523 Tausen went to Wittenberg, where he studied for a year and a half, when he was recalled to Antvorskov. In consequence of his professed attachment to the doctrines of Luther he was first imprisoned in the dungeons of Antvorskov and thence transferred, in the spring of 1525, to the Grey Friars' cloister at Viborg in Jutland, where he preached from his prison to the people assembled outside, till his prior, whom he won over to his views, permitted him to use the pulpit of the priory church. At Viborg the seed sown by Tausen fell upon good soil. Several young men in the town had studied at Wittenberg, and the burghers, in their Lutheran zeal, had already expelled their youthful Bishop Jörgen Friis. Tausen's preaching was so revolutionary that he no longer felt safe among the Franciscans, so he boldly discarded his monastic habit and placed himself under the protection of the burgesses of Viborg. At first he preached in the parish church of St John, but this soon growing too small for him he addressed the people in the market-place from the church tower. When the Franciscans refused to allow him to preach in their large church, the mob broke in by force. A compromise was at last arranged, whereby the friars were to preach in the forenoon and Tausen in the afternoon. The bishop, very naturally averse to these high-handed proceedings, sent armed men to the church to arrest Tausen, but the burghers, who had brought their weapons with them, drove back "the bishop's swains." In October 1526 King Frederick I., during his visit to Aalborg, took Hans Tausen under his protection, appointed him one of his chaplains, and charged him to continue for a time "to preach the holy Gospel" to the citizens of Viborg, who were to be responsible for his safety, thus identifying himself with the new doctrines in direct contravention of the plain letter of his coronation oath. Tausen found a diligent fellow-worker in Jörgen Viberg, better known as Sadolin, whose sister, Dorothea, he married, to the great scandal of the Catholics. He was indeed the first Danish priest who took unto himself a wife. He was also the first of the reformers who used Danish instead of Latin in the church services, the "Even song" he introduced at Viborg being of great beauty. Tausen was certainly the most practically gifted of all the new native teachers. But he was stronger as a preacher and an agitator than as a writer, the pamphlets which he now issued from the press of his colleague the ex-priest Hans Vingaard, who settled down at Viborg as a printer, being little more than adaptations of Luther's *opuscula*. He continued to preach in the Grey Friars' church, while Sadolin, whom he had "consecrated" a priest, officiated at the church of the Dominicans, who had already fled from the town. The stouter-hearted Franciscans only yielded to violence persistently applied by the soldiers whom their opponents quartered upon them. In 1529 Tausen's "mission" at Viborg came to an end. King Frederick now recommended him to Copenhagen to preach heresy at the church of St Nicholas, but here he found an able and intrepid opponent in Bishop Rönne. Serious disturbances thereupon ensued; and the Protestants, getting the worst of the argument, silenced their gainsayers by insulting the bishops and priests in the streets and profaning and devastating the Catholic churches. A *Herredag*, or Assembly of Nobles, was held at Copenhagen on the 2nd of July 1530, ostensibly to mediate between the two conflicting confessions, but the king, from policy, and the nobility, from covetousness of the estates of the prelates, made no attempt to prevent the excesses of the Protestant rabble, openly encouraged by Tausen. On the other hand, the preachers failed to obtain the repeal of the Odense recess of 1527 which had subjected them to the spiritual jurisdiction of the prelates. On the death of King Frederick, Tausen, at the instance of Rönne, was, at the *Herredag* of 1533, convicted of blasphemy and condemned to expulsion from the diocese of Sjaelland, whereupon the mob rose in arms against the bishop, who would have been murdered but for the courageous intervention of Tausen, who conducted him home in safety. The noble-minded Rönne thereupon, from gratitude, permitted Tausen to preach in all his churches on condition that he moderated his tone. On the final triumph of the Reformation Tausen was appointed bishop of Ribe (1542), an office he held with great zeal and fidelity for twenty years.

See Suhr, *Tausens Levnet* (Ribe, 1836); *Danmarks Riges Historie*, vol. iii. (Copenhagen, 1897–1905). (R. N. B.)

TAUSSIG, FRANK WILLIAM (1859–), American economist, was born at St Louis, Missouri, on the 28th of December 1859. He was educated in his native city and at Harvard University, where he became professor of political economy in 1892. He has made a particular study of finance, and has written *Tariff History of the United States* (1888); *The Silver Situation in the United States* (1892); *Wages and Capital* (1896). He was for some time editor of the *American Quarterly Journal of Economics*.

TAUTPHOEUS, JEMIMA, Baroness von (1807–1893), British novelist, was born at Seaview, Co. Donegal, on the 23rd of October 1807, her maiden name being Montgomery. In 1838 she married the Baron von Tautphoeus of Marquartstein (1805–1885), chamberlain to the king of Bavaria, and in Bavaria she passed most of the rest of her life. She was the author of several novels, written in English, describing South German life, manners and history. *The Initials* (1850), *Quits* (1857), and *At Odds* (1863) are the best known of these. She died on the 12th of November 1893.

TAVASTEHUS, a province of Finland, bounded by the provinces of Nyland, Viborg, Vasa and St Michel. Pop. (1904) 317,326. The province is largely unproductive, much of the surface being composed of hills and lakes, but in favourable districts agriculture is sucessfully pursued, and there is a school of agriculture and an institute of forestry.

TAVERN, the old name for an inn, a public house where liquor is sold and food is supplied to travellers. It is, however, now usually applied to a small ale-house where liquor only is supplied. The word comes through Fr. from Lat. *taberna*, a booth, shop, inn. It is usually connected with the root seen in "tabula," board, whence Eng. "table;" and thus meant originally a hut or booth made of planks or boards of wood.

TAVERNIER, JEAN BAPTISTE (1605–1689), French traveller and pioneer of trade with India, was born in 1605 at Paris, where his father Gabriel and uncle Melchior, Protestants from Antwerp, pursued the profession of geographers and engravers. The conversations he heard in his father's house inspired Tavernier with an early desire to travel, and in his sixteenth year he had already visited England, the Low Countries and Germany, and seen something of war with the imperialist Colonel Hans Brenner, whom he met at Nuremberg. Four and a half years in the household of Brenner's uncle, the viceroy of Hungary (1624–29), and a briefer connexion in 1629 with the duke of Rethel and his father the duke of Nevers, prince of Mantua, gave him the habit of courts, which was invaluable to him in later years; and at the defence of Mantua in 1629, and in Germany in the following year with Colonel Walter Butler (afterwards notorious through the death of Wallenstein), he gained some military experience. When he left Butler to view the diet of Ratisbon in 1630, he had seen Italy, Switzerland, Germany, Poland and Hungary, as well as France, England and the Low Countries, and spoke the principal languages of these countries. He was now eager to visit the East; and at Ratisbon he found the opportunity to join two French fathers, M. de Chapes and M. de St Liebau, who had received a mission to the Levant. In their company he reached Constantinople early in 1631, where he spent eleven months, and then proceeded by Tokat, Erzerum and Erivan to Persia. His farthest point in this first journey was Ispahan; he returned by Bagdad, Aleppo, Alexandretta, Malta and Italy, and was again in Paris in 1633. Of the next five years of his life nothing is known with certainty, but it was probably during this period that he became controller of the household of the duke of Orleans. In September 1638 he began a second journey (1638–43) by Aleppo to Persia, and thence to India as far as Agra and Golconda. His visit to the court of the Great Mogul and to the diamond mines was connected with the plans realized more fully in his later voyages, in which Tavernier travelled as a merchant of the highest rank, trading in costly jewels and other precious wares, and finding his chief customers among the greatest princes of the East. The second journey was followed by four others. In his third (1643–49) he went as far as Java and returned by the Cape; but his relations with the Dutch proved not wholly satisfactory, and a long lawsuit on his return yielded but imperfect redress. In his last three journeys (1651–55, 1657–62, 1664–68) he did not proceed beyond India. The details of these voyages are often obscure; but they completed an extraordinary knowledge of the routes of overland Eastern trade, and brought the now famous merchant into close and friendly communication with the greatest Oriental potentates. They also secured for him a large fortune and great reputation at home. He was presented to Louis XIV., "in whose service he had travelled sixty thousand leagues by land," received letters of nobility (on the 16th of February 1669), and in the following year purchased the barony of Aubonne, near Geneva. In 1662 he had married Madeleine Goisse, daughter of a Parisian jeweller.

Thus settled in ease and affluence, Tavernier occupied himself, as it would seem at the desire of the king, in publishing the account of his journeys. He had neither the equipment nor the tastes of a scientific traveller, but in all that referred to commerce his knowledge was vast and could not fail to be of much public service. He set to work therefore with the aid of Samuel Chappuzeau, a French Protestant littérateur, and produced a *Nouvelle Relation de l'Intérieur du Sérail du Grand Seigneur* (4to, Paris, 1675), based on two visits to Constantinople in his first and sixth journeys. This was followed by *Le Six Voyages de J. B. Tavernier* (2 vols. 4to, Paris, 1676) and by a supplementary *Recueil de Plusieurs Relations* (4to, Paris, 1679), in which he was assisted by a certain La Chapelle. This last contains an account of Japan, gathered from merchants and others, and one of Tongking, derived from the observations of his brother Daniel, who had shared his second voyage and settled at Batavia; it contained also a violent attack on the agents of the Dutch East India Company, at whose hands Tavernier had suffered more than one wrong. This attack was elaborately answered in Dutch by H. van Quellenburgh (*Vindiciæ Batavicæ*, Amst., 1684), but made more noise because Arnauld drew from it some material unfavourable to Protestantism for his *Apologie pour les Catholiques* (1681), and so brought on the traveller a ferocious onslaught in Jurieu's *Esprit de M. Arnauld* (1684). Tavernier made no reply to Jurieu; he was in fact engaged in weightier matters, for in 1684 he travelled to Berlin at the invitation of the Great Elector, who commissioned him to organize an Eastern trading company—a project never realized. The closing years of Tavernier's life are obscure; the time was not favourable for a Protestant, and it has even been supposed that he passed some time in the Bastille. What is certain is that he left Paris for Switzerland in 1687, that in 1689 he passed through Copenhagen on his way to Persia through Muscovy, and that in the same year he died at Moscow. It appears that he had still business relations in the East, and that the neglect of these by his nephew, to whom they were intrusted, had determined the indefatigable old man to a fresh journey.

Tavernier's travels, though often reprinted and translated, have two defects: the author uses other men's material without distinguishing it from his own observations; and the narrative is much confused by his plan of often deserting the chronological order and giving instead notes from various journeys about certain routes. The latter defect, it is true, while it embarrasses the biographer, is hardly a blemish in view of the object of the writer, who sought mainly to furnish a guide to other merchants. A careful attempt to disentangle the thread of a life still in many parts obscure has been made by Charles Joret, *Jean Baptiste Tavernier d'après des Documents Nouveaux*, 8vo, Paris, 1886, where the literature of the subject is fully given.

See also an English translation of Tavernier's account of his travels so far as relating to India, by V. Ball, 2 vols. (1889).

TAVIRA, a seaport of southern Portugal, in the district of Faro (formerly the province of Algarve); at the mouth of the river Seca, 21 m. E.N.E. of Faro. Pop. (1900) 12,175. The harbour is protected by two forts, and the public buildings include a Moorish citadel, a Renaissance church, and a ruined nunnery founded by King Emanuel (1495–1521). Tavira has sardine and tunny fisheries, and carries on a considerable coasting trade. Excellent fruit is grown in the neighbourhood.

TAVISTOCK, a market town in the Tavistock parliamentary division of Devonshire, England, in the valley of the Tavy, on the western border of Dartmoor; 16½ m. N. of Plymouth, on the Great Western and the London and South Western railways. Pop. of urban district (1901), 4728. There are some remains (including a portion in the square, now used as a public library established in 1799) of the magnificent abbey of St Mary and St Rumon, founded in 961 by Orgar, earl of Devon. After destruction by the Danes in 997 it was restored, and among its famous abbots were Lyfing, friend of Canute, and Aldred, who crowned Harold II. and William, and died archbishop of York. The abbey church was rebuilt in 1285, and the greater part of the abbey in 1457–58. The church of St Eustachius dates from 1318, and possesses a lofty tower supported on four open arches. Within are monuments to the Glanville and Bourchier families, besides some good stained glass, one window being the work of William Morris. Kelly College, near the town, was founded by Admiral Benedictus Marwood Kelly, and opened in 1877 for the education of his descendants and the orphan sons of naval officers. Mines of copper, manganese, lead, silver and tin are in the neighbourhood, and the town possesses a considerable trade in cattle and corn, and industries in brewing and iron-founding. The mining industry generally has declined, but there is a trade in arsenic, extracted from the copper ore.

The early history of Tavistock (*Tavistoke*) centres round the abbey of St Rumon. Both town and abbey were sacked by the Danes in 997, but were shortly afterwards rebuilt, and the latter at the time of the Conquest ranked as the wealthiest house in Devon, including the hundred and manor of Tavistock among its possessions. Tavistock was governed from before the Conquest by a portreeve, who in the 14th century was assisted by a select council of burgesses, styled in 1660 "the Masters of the Toune and Parish of Tavistock." It returned two members to parliament as a borough from 1295 until deprived of one member by the act of 1867, and finally disfranchised by that of 1885, but no charter of corporation was granted until 1683, when Charles II. instituted a governing body of a mayor, twelve aldermen and twelve assistants; with a recorder, deputy recorder, common clerk and two sergeants-at-mace. A market on Friday and a three days' fair at the feast of St Rumon were granted by Henry I. to the monks of Tavistock; and in 1552 two fairs on April 23 and November 28 were granted by Edward VI. to the earl of Bedford, then lord of the manor. In the 17th century great quantities of cloth were sold at the Friday market, and four fairs were held at the feasts of St Michael, the Epiphany, St Mark, and the Decollation of St John the Baptist. The charter of Charles II. instituted a Tuesday market and fairs on the Thursday after Whitsunday and at the feast of St Swithin. In 1822 the old fairs were abolished in favour of six fairs on the second Wednesdays in May, July, September, October, November and December. The Friday market is still held. Tavistock was one of the four stannary towns appointed by charter of Edward I., at which tin was stamped and weighed, and monthly courts were held for the regulation of mining affairs. It was also the site of one of the earliest printing-presses, and copies of the stannary laws and of a translation of Boethius issued from the Tavistock press in the reign of Henry VIII. are preserved in Exeter College library. The decay of the woollen industry at Tavistock was attributed by the inhabitants in 1641 to the dread of the Turks at sea and of popish plots at home. The trade is now extinct. The copper-mining industry has much declined. The Royalist troops were quartered here in 1643 after the defeat of the Parliamentary forces at Bradock Down.

See *Victoria County History, Devonshire*; A. J. Kempe, *Notices of Tavistock and its Abbey* (London, 1830); R. N. Worth, *Calendar of Tavistock Parish Records* (Plymouth, 1887).

TAVOY, a town and district in the Tenasserim division of Lower Burma. The town is on the left bank of the river of the same name, 30 m. from the sea. Pop. (1901) 22,371. It carries on a considerable coasting trade with other ports of Burma, and with the Straits Settlements. The chief industry is silk-weaving, but there are also rice and timber mills.

The district has an area of 5308 sq. m. It lies between Siam and the Bay of Bengal, enclosed by mountains on three sides, viz., the main chain of the Bilauktaung on the east, rising in places to 5000 feet, which, with its densely wooded spurs, forms an almost impassable barrier between British and Siamese territory; the Nwahlabo in the centre, which takes its name from its loftiest peak (5000 ft.); and a third range, under the name of Thinmaw, between the Nwahlabo and the sea-coast. The chief rivers are the Tenasserim and Tavoy, the former being formed by the junction of two streams which unite near Met-ta; for the greater part of its course it is dangerous to navigation. The Tavoy is navigable for vessels of any burden. It is interspersed with many islands, and with its numerous smaller tributaries affords easy and rapid communication. The climate is on the whole pleasant. The annual rainfall averages 228 inches. Pop. (1901) 109,979, showing an increase of 16 per cent. in the decade. The staple crop is rice. Forests cover an area of nearly 5000 sq. m., of which 960 sq. m. are "reserved."

Tavoy, with the rest of Tenasserim, was handed over to the British at the end of the first Burmese war in 1824. A revolt broke out in 1829, headed by the former governor, which was at once quelled, and since then the district has remained undisturbed.

TAWDRY, an adjective used to characterize cheap finery, and especially things which imitate in a cheap way that which is rich or costly, or adornments of which the freshness and elegance have worn off. The word is first used in combination in the phrase "tawdry lace," a shortened form or corruption of St Audrey's or St Awdrey's lace. St Audrey was St Etheldreda, who founded Ely cathedral, and it is generally accepted that tawdry-laces or tawdries were necklaces bought at St Audrey's Fair on the 17th of October. Nares (*Glossary to the Works of English Authors*, 1859) gives as an alternative the story that the saint died of a swelling in the throat, which she took as a judgment for having worn fine necklaces in her youth.

TAXATION (from "tax," derived, through the French, from Lat. *taxare*, to appraise, which again is connected with the same root as *tangere*, to touch), that part of the revenue of a state which is obtained by compulsory dues and charges upon its subjects. The state may have revenue from property of its own. In past times one of the principal sources of the revenue of the sovereign was in fact property of some sort, of which the crown lands in Great Britain, still administered by the government, are a remnant. In other countries, even at the present time, there is a large public domain yielding revenue. Local authorities also largely own property from which a revenue is obtained. But as a rule, and in spite of what has often been the practice in the past, and of exceptions which may still exist in some countries, a government obtains the money required for its expenses by means of taxation. Some of the apparent exceptions, moreover, appear to be only exceptions in name. It is contended, for instance, that the revenue from land obtained by the government of India is in reality of the nature of a land rent—a species of property owned by the government. But the fact of a government levying so general a charge may be held *ipso facto* to convert the charge into a tax, having much the same economic effects and consequences as a tax. When, moreover, a state receives a revenue from property, some of the economic consequences may be the same as if it received the money by means of a tax. In both cases there is absorption and administration by the state of so much of the income of the community, and it may be a question whether the private ownership of the property would not be more expedient both for the state and its subjects than state ownership is, in spite of the apparent advantage to all concerned in the state getting so much of its income without the compulsion of a tax.

The Different Kinds of Taxes.—In the economic development of states taxes have come to be grouped in different ways, according to variations in the method of levying them or the means of enforcing compulsion or other differences. One of the most usual divisions is into *direct* and *indirect* taxes. Taxes are distinguished as direct, because they are charged directly upon the tax-payer from whose income they are supposed to be taken. Indirect taxes are those where it is recognized from the beginning that the individual who pays in the first instance usually passes on the charge to some one else, who may again pass it on until it finally reaches the subject who bears the burden. The income tax, a direct charge upon all incomes above a certain limit, is the principal type in the United Kingdom of a direct tax. In France there is a group of taxes known by that name—a land tax, a personal and furniture tax, a door and window tax, and a trade licence tax. In the United States there are mainly assessments of the capital value of property, always for state and local purposes only, and not for the central government. Among the indirect taxes the most important are excise and customs duties upon articles of general consumption, the principal articles almost everywhere being spirits, beer and tobacco. Sugar, tea, coffee and cocoa are also among the articles commonly selected. In essential character there is no difference between excise and customs duties, except that excise duties are levied upon articles of home production, and customs upon articles imported from abroad, or brought into one part of a country or empire from another part; but excise duties on the whole are considered more likely to interfere with trade, in consequence of the necessity of supervising the production of the articles affected. Next in importance to excise and customs we have duties levied by means of *stamps* upon documents or by charges at the time of registering deeds to which registration is necessary for the purpose of being valid. The charge in one case upon the article at a certain stage of its production, and in the other upon a transaction, is supposed to be passed on by the first payer to others. With these have been usually classed in the United Kingdom certain licence taxes upon traders, although such licences in France are reckoned direct taxes.

This division into direct and indirect is, however, far from logical. To take first the direct taxes. The income tax itself is not, in all cases, really paid to the state directly by the person out of whose income it comes. It is paid, in the first instance, in the case of land or houses, by the occupier, and where the occupier is a tenant it is recovered by him from the owner. In the case of joint-stock companies the company pays the state, and deducts the amount from the individual owners of stocks and shares out of whose incomes the amount comes. The ultimate payer in these cases is no doubt reached without delay or many steps, but the process is not quite direct. It is the same with rates. A householder is assessed as occupier, but he may be "compounded for," and really know nothing of the payment, though it is supposed to come out of his income. In the case, again, of a long-established land tax or rate many questions may arise as to whether the person who is considered to bear the burden in the first instance really bears it in the end. It is contended by some that the tax becomes in the nature of a rent-charge upon the property affected, and that the state really acts as landowner in levying the charge just as it does in receiving the rent of crown lands, and with similar economic incidents and consequences. Thus the direct taxes so called may frequently be no more direct than any others.

As regards indirect taxes, again, there appear to be some cases at least where it is by no means certain that the charge is passed on; stamp duties, for instance, especially where moderate in amount, may have the effect of diminishing *pro tanto* the profits in business of the person paying them, or the income which he enjoys. Where they are heavy, as, for instance, with the French registration duties on the transfer of property, there appears to be little doubt that they constitute a deduction from the price which a seller receives, and thus they are direct enough. Sometimes also, when a charge upon a commodity is not of such a figure as to be easily divisible among the ordinary units of retail consumption, so that it can be passed on to a consumer of the articles in the form of an increased price, it may remain fixed upon those who first pay it, at least for a time. This is supposed to have actually happened with the increase of the beer duty in the British budget of 1894 by 6d. per *barrel*—a sum which would not when divided by the pints in a barrel amount to the smallest coin of the realm. When the multure tax, a tax upon milling grain, was imposed in Italy many years ago, it was found that no corresponding increase took place in the price of flour and bread. The trade fell into the hands of the millers on a large scale, who paid the tax out of their increased profits from larger business, while the smaller millers were crushed out; so that this was manifestly the case of a tax, so called indirect, where the whole burden really fell on those who paid the charge in the first instance, and who in theory were supposed to pass it on to others. Even in the case of indirect taxes, therefore, there are important exceptions to the rule that they are indirect.

The division of taxes into direct and indirect is thus based on no real intrinsic difference. It is a classification for convenience' sake, adopted upon a rough observation of conspicuous, or apparently conspicuous, differences in the mode of levying taxes, and nothing more. The division, nevertheless, cannot be passed over without mention, as it is not only a common one in economic writing, but it figures largely in budget statements, financial accounts, and finance ministers' speeches—especially in the United Kingdom and France. In the United Kingdom the distinction has been made familiar by free-trade discussions. Direct taxation in the shape of income tax was substituted for indirect taxation previously levied, in order to relieve trade from the shackles of duties and charges which had become all-embracing. In France the direct taxes above referred to are described officially as direct, having been originally, there is little doubt, the main sources of government income; and there is equally an official designation of certain heads of revenue as "*contributions et taxes indirectes*." Recently in budget debates in England there has been much comparison of the amounts yielded at different times by direct and indirect taxes respectively.

Other general classifications of taxes have also been attempted, as, for instance, taxes upon real property, and taxes upon personal property, and so on. Classification is indeed only too easy. Applying a characteristic common to some taxes, we can make a group of them, and set them against a group of all the other taxes lumped together. Such classifications are, however, uninstructive, and it has been found practically necessary in financial writing to take the principal taxes by name, or by such a general grouping as that of import or stamp duties, and then describe their nature, characteristics and incidence. In this way each country has a grouping of its own, though there is a common likeness, and the experience and practice of one country assist the financial study of another. As Adam Smith remarks, there is nothing in which governments have been so ready to learn of one another as in the matter of new taxes.

Descriptions of Taxes.—Following the practice of authors on finance, we may give a short account of the principal taxes in the United Kingdom, with references in passing to points of comparison or contrast with the taxes of other countries. See, however, also the article on ENGLISH FINANCE.

The income tax (*q.v.*) for many years has been the most prominent, and latterly it has been the most productive, single tax. Its technical name is the property and income tax, but it is essentially a charge upon all incomes or profits, whether arising from property, or from the remuneration of personal services, or from annuities, income being applied with the widest possible meaning. As originally instituted in April 1798, during the great war with France, under the name of a "triplicate assessment," it was rather a consolidation of various assessed taxes levied upon the luxuries of the rich and upon property, than a wholly new tax. In December of the same year this impost was repealed, and a true income tax of 10 per cent. established on all incomes over £60, with abatements between £60 and £200. It was intended as a temporary tax for war purposes only, and was repealed in 1802, but was re-imposed when the war recommenced in 1803, with the limit of abatement reduced to £150. So odious was it that parliament in 1815, when the war came to an end, ordered the destruction of the documents relating to it. Its efficiency as an instrument of producing revenue was, however, so great as to lead to its revival in 1842, when Sir Robert Peel inaugurated his great free-trade reform and swept away duties on exports, duties on imported raw material, and other imposts hampering the trade of the country. The intention again was that the tax should be temporary, but although the free-trade work was practically completed in the early 'sixties, and Mr Gladstone went so far as to dissolve parliament in 1874 with a promise that he would abolish the tax if his party were returned to power, it has become a permanent impost. The reasons are that with the tax at a low rate it has been found much less intolerable than during the Napoleonic War, when it was at the rate of 10 per cent., while the pressure of the tax has also been greatly mitigated by placing very high the minimum income subject to it, and giving abatements upon the lower taxable incomes. These expedients have since been carried much farther. The tax, if kept at a low rate, undoubtedly fulfils a useful function as a revenue reserve for emergencies, on account of the ease with which it can be put up and down without disturbing trade. But in recent years, by rising to the rate of 1s. 2d. per £, it has been felt more heavily, and at this height is decidedly less elastic. As regards this tax at least there is no question of its "directness" in a sense, as it is so contrived that it can hardly be passed on by those who are struck at, though they are not always the same as those who pay in the first instance, as has already been pointed out. There have been great complaints also of injustice by the possessors of temporary and precarious incomes, who have to pay the same rate of tax as the owners of permanent incomes from property, although these complaints have been diminished to some small extent by the raising of the minimum limit of the income assessed and the increase of the principle of abatements.

The varieties of income charged being very great, and special claims for consideration having been set up at different times, the result has been the formation of an income tax code, defining the methods and rules for assessing the different classes of profits and income, and prescribing the way in which abatements and exemptions are to be obtained. A leading peculiarity is the avoidance of special inquisition into the aggregate of individual incomes. Although it is called a direct tax, the method of levy, as far as property is concerned, is upon the profits at their source, and not as they are distributed among the receivers. The question of the amount of individual incomes only comes before the authorities when claims for exemption and abatement are made. The character of the tax is accordingly much less odious than it would be if an account of individual incomes were invariably demanded, as was the case in the United States during the Civil War, when an income tax existed for a short time.

Other taxes grouped with the income tax by the authorities are house duty and land tax, but they are unimportant by comparison. The house duty replaced a window tax and other charges which were formerly not unimportant, especially in the interval between 1815 and 1843, when there was no income tax. It is a charge upon the occupiers of houses, mainly dwelling-houses, according to the amount of rent, the rate upon dwelling-houses ranging from 3d. to 9d. in the £, and the yield being about £1,750,000 per annum. The incidence is probably much the same as that of the income tax itself, though there are curious questions as to the ultimate incidence as between owners and occupiers of houses. The land tax is quite unimportant, being an ancient tax upon an old assessment which has long become obsolete, and it interests economists most of all by the illustration it furnishes of what may be called a rent-charge tax—a tax, that is, which has been so long in existence and so fixed in its basis that it becomes in reality a charge upon the property, and not a direct burden upon the person who pays it, as the income tax is upon the person who pays it or for whom it is paid. In 1897 the basis of the tax was varied, but not in any way to affect the principle just stated.

The next great group of taxes is that of the excise (*q.v.*) and customs duties upon commodities. Excise duties are charges upon commodities produced at home on their way to the consumer, and customs duties in the United Kingdom are charges upon commodities brought into the country from abroad; and they are of essentially the same nature. Not only so, but excise duties and customs duties are in some cases supplementary to each other, like articles being produced at home and imported from abroad, so that for the sake of the revenue they have both to be taxed alike. Of this in the British system spirits are the best instance.

Export duties, it may be observed, are not important in systems of taxation generally, as there are few articles where the charge will not really fall on the wages of labour and profits of capital within the country imposing them; but opium grown in India is a well-known exception, and in the West Indies export duties on principal articles of production, in spite of their incidence, have been found a convenient source of revenue.

The list of commodities selected for taxation in the English fiscal system, under Free Trade, is very small. Few countries have so short a list of import duties, but this is in consequence of their design to give protection, which raises totally different questions from those of revenue.

The next large group of taxes is that of the stamp duties (*q.v.*). The principal items are those derived from a stamp of 1d. upon each cheque or receipt for money paid, and from a variety of charges on deeds and other instruments, and principally on the price paid for the transfer of real property and of stocks and shares, and on mortgages. Included are various charges on foreign bonds to bearer, to compensate for the advantage they have in escaping the transfer duty on deeds, through their passing on sale or mortgage from hand to hand. The essence of the compulsion in the case of stamp duties is the invalidity of the documents in courts of law unless the stamp is affixed, besides liability to penalties for not affixing the proper stamps. As things go in matters of taxation, English stamp duties are low. In France, besides the stamp duties, there are charges on the transfer of real property amounting to about 6 per cent. on the official registration of the transfer which is necessary to make it effective.

We come next, in dealing with taxation, to a group of charges about which the question has been raised as to whether they are, properly speaking, taxes or not. These are the post office charges, and the charges for telegraph service, including telephones. In the classification of the revenue in English budgets and in official returns these charges are deliberately separated from the above sources of the revenue described as taxes, and classed with "revenue derived from other sources." The correctness of this procedure is questionable. According to old usage, the post office was made a state monopoly for the express purpose of levying taxation by means of it. In France the postage on letters is still called the *taxe des lettres*. There is no doubt also, that when postage on letters is charged at the rate of 1d. each, where the cost of collection and delivery, as in the metropolis, is perhaps not more than a tenth of a penny, it is difficult to distinguish the levy from that of any other tax. The excuse, as a rule, may hold good, that the postal charge is only a reasonable one for service rendered, so that the net income of the post office really resembles the profit of a business, but the element of taxation appears undoubtedly to enter. The same remark would apply to the charges for passenger conveyance and goods freight made by governments which carry on railway business, as in Prussia, India and the Australian states. In strict theory, where the *government* makes a charge, it levies a tax. The reasonableness of the charge in a given case is to its credit, but the features of monopoly and compulsion on the tax-payer make the charges difficult to distinguish logically from other taxes. The facts are not in dispute, however they may be described. If the government derived a large income from post office and telegraph service in excess of the amount expended, the whole income would be generally, and not improperly, described as taxation; but consideration, of course, must be given to the difference made by the working of the service generally for the public advantage rather than for purposes of revenue.

Another source of revenue in British imperial finance is that from fees in courts of justice, patent stamps and the like, which is usually classified, like the income of the post office, as revenue derived from other sources than taxes. The amount is not large, though unfortunately it is not exactly known, owing to the fees being treated in many cases as extra receipts, and deducted from the expenditure of the departments by which they are received, so that this part of the national expenditure is not shown in the accounts at all. The proceeding appears to be quite incorrect, whatever excuse there may be for treating revenue like that of the post office as non-tax revenue. Fees levied on proceedings in courts of justice are not only taxes, but taxes of the worst sort. They received the special condemnation of Jeremy Bentham. It is a blot on British finance, therefore, that this part of the taxation is treated as if it were not taxation at all, and largely concealed from view in the way described.

Last of all, we have to notice among the imperial taxes the estate (*q.v.*) or death duties, as they are called—the charges made by government on the transfer of property from the dead to the living. These have been considerably increased in amount. Various interesting questions arise regarding them. Logically they are apparently taxes upon the dead, as they limit the area of bequest, but they are felt by the living who receive the estate as if the burden of taxation fell on them. Practically, when a stranger receives the estate of a deceased man, the proper way of viewing the tax would appear to be that it is a share of property claimed by the state against a stranger who has no right in the matter except that which the state gives him, so that it is hardly a tax at all, as the word is usually understood; but when the estate is received by the near relatives of the deceased who were subsisting upon it even before his death, it is undoubtedly felt as a tax by them, and operates as a tax. It is even at times a very burdensome tax, falling upon a family when its sources of income are otherwise diminished, while it has the demerit of striking a small number annually instead of being diffused equally. Death duties also raise the question as to their being taxes upon capital. They are of large amount, even at the lowest rates of 1 to 4 per cent. upon the capital charged, and they have to be paid at such times as to cause their being paid out of capital and not out of income, so that their tendency is to diminish the capital available for productive enterprises.

Local Taxation.—Besides the above revenue from taxation for imperial purposes, large amounts are raised for local purposes. The local authorities derive a large income from private property, and from monopolies such as water, gas, electric light, telephones and tramway service, which they carry on, and on which the same observations may be made as on the post office and telegraph services; but in addition there is a large amount of taxation. The principal portion of this taxation consists of rates, that is, a direct charge upon the income or rental of real property, such as lands, houses, railways and mines, but mainly lands and houses. Rates are even a more important factor in direct taxation than the income tax, and they have given rise to even greater complaints and discussion. In 1896 a special royal commission was appointed, under the chairmanship of Lord Balfour of Burleigh, to consider the problems of the rates; it made several elaborate reports, the final one appearing in 1901. The most important questions raised in a scientific view appear to be the misconception of the whole problem of local taxation by governments. Rates were originally imposed, there is little question, when the intention was to tax all local incomes equally, and this is still the intention in the local taxation of the United States as well as the United Kingdom. Rates were imposed, therefore, on all kinds of property and the income arising from them, just as they are imposed in the United States on the capital of the property itself. But it has been found in practice that for various reasons only real property, which is visibly local and cannot be moved away, can be assessed and made to pay. The owners of real property, however, continually urge that they are unfairly treated, and that other property should be rated. Next there has been misconception, arising from the same cause, in the constant attempt to charge the occupier of lands and houses with rates, although the real effect of the rates must be, as a rule, to diminish the value of the property affected like an old-established land tax, so that rates, properly speaking, do not fall upon either owner or occupier. It would be hard, however, to persuade the mass of occupiers in England that they do not pay the rates, so that the expedient of dividing the rates between owner and occupier, though it cannot affect their real incidence to a substantial extent, constantly finds favour. The confusion has been further increased of late years by attempts, as far as towns are concerned, to find a new subject of taxation in what are called *site values*, as if rates themselves were not in reality an appropriation by the state of a portion of the whole value of the property, subject to which all the other interests exist. It would be impossible here even to state all the questions that have arisen about rates; but the essential confusion caused by the neglect of practical men to study the natural history of taxation, as it may be called, must be obvious to every student. The frank recognition that local income taxes are impossible, and that taxation on property for local purposes can only be applied to real property, where it becomes, usually or frequently, in the nature of a rent-charge, would have saved the legislature and the public an infinity of laborious discussion.

Other taxes for local purposes comprise dues and tolls, such as harbour dues, where the money is required for such a definite purpose as a harbour, maintained at the expense of the traffic accommodated. Here again the question arises as to whether the tax is a mere compulsory charge or payment for a service rendered. Among these tolls may perhaps be included some charges in the nature of *octroi* dues, imposed on commodities entering a town, but not to a great extent. Such dues, in the nature of customs, are very common in continental cities, and yield large revenue to the local authorities, although they have been very generally, if not quite universally, abolished in the United Kingdom. They have been regarded with much dislike by most economists, and some dues of the kind which existed in London, viz., dues on coal and wine imported, and metage dues on grain, were much imposed until their final abolition in recent years. When of moderate account, however, dues of this sort appear no more objectionable than harbour dues already mentioned, or any other moderate charges on transactions. If of large amount and very numerous, they hamper trade, as all taxation tends to do, but that is no reason for condemning them specially when the choice lies between them and other forms of taxation.

In addition, we have to notice certain taxes which up to 1910–11 were levied by the British government and distributed to the local authorities, just as in France the government levies certain direct taxes, or *centimes additionnelles*, added to its own direct taxes for the benefit of the local authorities. These taxes were additional beer and spirit dues (customs and excise), excise licences, and share of probate and estate duty. The remarks already made on the corresponding taxes levied for imperial purposes of course apply to these. Exceptionally, it may be added, as regards the licence taxes, which occupy quite an inferior place in the British system of taxation for imperial purposes, that the question whether some of them are not really direct in their incidence on the first person charged may also be raised, although they are classed with indirect taxes. Many of the licences are those of brewers, distillers and publicans, and others in trade, and are paid out of the general profits of the business, so that they can hardly be passed on to the consumers, while other licences are for shooting, for employing carriages and men-servants, and for similar objects, where the charge on the payer is direct. This may be the place to mention that in other countries, as in France, the licence duties on traders are more general than in the United Kingdom, and are levied on an elaborate scale, according to the size of population of the town where the business is carried on, and the rent paid for the premises. They take the place, to some extent, of the income tax, and are usually classed with the direct taxes.

The peculiarity of taxes which are levied by the imperial authority and distributed among the local authorities for disbursement deserves notice. There must be a general cause for such an arrangement when we find it to have been in existence in France and other countries, and to have been introduced into the United Kingdom. And this cause no doubt is the need of the local authorities, and the difficulty of letting them have taxes of their own to levy which do not interfere with the imperial monopoly. The arrangement is obviously objectionable on the score of its conducing to local extravagance, as local authorities are not likely to be so economical with money that comes to them from the outside, as it were, as they would be with money directly taken from their own pockets. Local authorities receive other subventions and aids from the central government besides the proceeds of these taxes, so that their appropriation for local needs is related to a large question which belongs, however, to the general subject of local government, and not so much to the special subject of taxation.

Incidence of Taxation.—In describing the principal taxes which are employed in the United Kingdom to provide for the national expenditure, observations have necessarily been made upon the incidence, probable or assumed, upon the taxpayer, and on the question how far they may fall equally on the whole community without any special incidence being traceable. The incidence of taxation is, however, a special subject for discussion, and is connected with various large issues, such as that of Free Trade, which are of deep interest to economic students.

The starting-point of discussions as to incidence of taxation is a classical passage in Adam Smith's *Wealth of Nations* (book v. chap. ii.), where he lays down the following maxims with regard to taxes in general: 1. The subjects of every state ought to contribute towards the support of the government, as nearly as possible, in proportion to their respective abilities; that is, in proportion to the revenue which they respectively enjoy under the protection of the state. 2. The tax which each individual is bound to pay ought to be certain and not arbitrary. 3. Every tax ought to be levied at the time or in the manner in which it is most likely to be convenient for the contributor to pay it. [Adam Smith specially praises indirect taxes on commodities under this head, because the consumer "pays them by little and little as he buys the goods," and "it must be his own fault if he ever suffers any considerable inconveniency from such taxes."] 4. Every tax ought to be so contrived as both to take out and keep out of the pockets of the people as little as possible over and above what it brings into the public treasury of the state. [This last passage is specially directed against taxes which are expensive to collect, or discourage trade, or offer temptation to smuggling, or subject people to frequent visits of the tax-gatherer.] These maxims have commanded universal assent, as they are obviously the common sense of the subject.

It may be observed, however, that while general maxims are easy, the application presents difficulties, and since Adam Smith wrote, and especially in modern times, new questions of some interest have been raised. Adam Smith does not go minutely into the incidence of taxation. Taxes in his view must come out of rent, or profit, or the wages of labour; and he observes that every tax which falls finally upon one only of the three sorts of revenue "is necessarily unequal in so far as it does not affect the other two," and in examining different taxes he disregards as a rule this sort of inequality, and confines his observations "to that inequality which is occasioned by a particular tax falling unequally upon that particular sort of private revenue which is affected by it." Recent discussion, however, has gone rather to the point which Adam Smith neglected, that of inequality generally, not merely as between different sorts of income, but as between individuals and classes. The whole burden of taxation, it is maintained, should fall equally upon classes and individuals as far as possible, and, if necessary, taxes falling equally upon special sources of private revenue should be balanced against each other in order to obtain the desired result. Along with this view has arisen the question whether the burden of taxation should not be *progressive*—the proportion of the sum taken by the state from the tax-payers increasing with the wealth of the individual; because ability to pay taxes is assumed to be not in proportion to, but to increase with the size of, the income.

What opinion should be held regarding this modern view as to equality in taxation, which differs so widely from anything countenanced by Adam Smith, though his language is echoed in it? The answer must be that, however sound, the view is for the most part far too ambitious. One difficulty is caused by the large proportion of the taxes in almost every system of taxation, and at any rate in the British system, where the exact incidence is in no way traceable, or where there is no sort of general agreement as to the incidence. The whole of the British revenue from post office and telegraph service, and the whole of the stamp revenue, are derived from charges whose exact incidence cannot be traced. We have seen, indeed, that doubt is even felt as to whether post office and telegraph charges can be treated as taxes at all. Again, the death duties are in a distinct category, these duties falling each year not on a particular class of the community, or a particular kind of property, but on a few individuals only, who are in some cases treated severely, while others may have no cause of complaint. In the course of fifty years, it may be said, the balance will be rectified, and the whole class to which the individuals belong, and the property they own, will be visited in turn, so that this taxation should be credited to them in an account of the incidence of taxes generally; but fifty years is altogether too long a period for such adjustments to be made. Thus a very large proportion of the total revenue cannot be made available for an account showing the incidence of taxation. There remain principally the income tax and one or two minor "direct" taxes, and the customs and excise duties. These, it is said, can be distributed among different classes of tax-payers, because the income tax falls on the owners of incomes of all kinds of property subject to the duty, if their incomes are above a certain limit, while the incidence of customs and excise duties can be ascertained by inquiries as to the consumption of dutiable articles by different classes. Even here, however, formidable difficulties are presented. The payers of income tax, unfortunately, are not one class but many, and although the rate of duty is the same, the definition of income seems imperfect, so that many pay on a much larger assessment of income than seems fair in comparison with other incomes of nominally the same amount, but really of much greater value when all deductions from the gross sum are fairly reckoned. If all who pay income tax are lumped together and contrasted with those who do not pay, then there is a false division to begin with, and there is so far no means of establishing equality or inequality. As regards indirect taxes, again, there appears no small difficulty in ascertaining the relative consumption of different classes, for the simple reason that in the same class so called the habits of consumption differ widely. It is only by a wide extension of the term "working man," for instance, that a class which includes a steady mechanic earning 30s. to £2 a week, who is frequently a total abstainer, and a labourer of inferior capacity and character earning 15s. to 20s. a week, and who is *not* a total abstainer, can be spoken of as one, and credit given to the *one* class for so much taxation on spirits, beer, tobacco, wine, tea and sugar. There are also geographical differences of a serious kind. On the other hand, the consumption by the income tax paying classes of customs and excise articles must vary indefinitely amongst themselves, according to personal habits, size of families, and even their geographical distribution. A further difficulty is furnished by a question as to whether the employer of domestic servants who gives them their board does or does not bear the burden of the duties on the articles which they consume, and which he buys for their use. Theoretically the burden falls on them as consumers. They would have more real wages, it is said, if the price of the articles they consume was not raised by taxation. But practically most employers are convinced that they pay the taxes for their servants. To establish, therefore, any fair account of the incidence of indirect taxes on different classes of the community, real classes being distinguished, and not a mere rough grouping into so-called classes of units who are altogether heterogeneous, is probably beyond the skill of man.

All this is evident on a view of imperial taxation alone. In studying equality, moreover, local taxation must be brought into view, with even more impracticable differences of opinion as to the real incidence of the taxation. The moment rates are brought into question it is seen at once how impossible it would be to establish equality among tax-payers, when owners on one side and occupiers on the other claim that they each bear the burden of the same taxes, and economists favour the opinion that much of the burden is in the nature of a rent-charge on the property, and in any case is equally diffused over the whole community.

Adam Smith was thus not altogether badly advised in not carrying his investigations into the equality of taxation farther than he did. There was another reason for his so doing in the heaviness of the burden of taxation at the time he wrote, governments exacting as much as they could, and being only desirous of finding the easiest means of doing so. It is the very lightness of taxation in recent years which has suggested the possibility of comparing the relative burdens of different classes, which would have seemed quite hopeless with a high taxation and an immense variety of high taxes. The conclusion that with good taxes long established the burden of taxation tends to become equal over the whole community was certainly not ill founded in the circumstances of former times, and may be accepted as true even in the present day.

As to progressive taxation based on the assumption that equality requires a larger proportionate charge upon a big income than on one of a smaller amount, the practical application of the principle, if true, would be impossible. A great deal more would need to be known than is now known as to the effect of taxes on different classes, and the aggregate amount of different incomes, before such a task could be undertaken. If there is a greater proportionate charge already on the larger incomes, nothing more need be done, and we cannot know that there is not. As to the justice of such a progressive tax, there is a common opinion in its favour among economists, at least to the extent of exempting a certain minimum of subsistence from taxation; but the present writer, after accepting this view in early life on the authority of Mill, must now express the greatest doubt. The ideal is equality, and no measure of a minimum of subsistence can really be devised.

Of course there may be single taxes which are progressive in form, such as the licence tax in France, or the income tax in Great Britain, where progression is established by abatements, or the death duties, where progression by scale is very common. But such progression may arise in a different way and on different principles from those proposed in defence of a general system of progressive taxation. It may be expedient for balancing taxation and roughly redressing palpable inequalities, and may be adopted for that purpose and no other.

Statistical inquiries as to the incidence of taxation or of particular taxes, though ideal or even approximate equality of a palpable arithmetical kind is practically unattainable by governments, are not altogether to be put aside. The information thus obtainable may be useful as far as it goes, indicating the directions in which the burden of taxation may press, and forming a guide of some utility when changes of taxation are contemplated. Calculations, for instance, as to what people at the lower levels of the income tax must pay because they happen to be struck by every sort of tax as no other class is, and calculations as to the freedom from taxation of large numbers of other classes whose habits of consumption and living enable them to escape the tax-gatherer as the class to which they belong cannot generally do, may help a finance minister in the selection of taxes to be repealed or reduced or to be newly imposed. With every effort after equality he must fail to satisfy all, but friction may be diminished and the work of carrying on government quietly and steadily facilitated.

Taxes and Free Trade.—Taxation ought not to interfere with trade if possible, and the object of Adam Smith's maxims, as we have seen, was largely to erect sign-posts warning finance ministers against the kind of taxes likely to harass traders. There has been much discussion, however, on free trade since Adam Smith's time, and the far-reaching nature of his warnings is not even yet generally understood. There will probably be general agreement as to the wisdom of avoiding taxes which are uncertain and arbitrary, or which involve frequent visits of the tax-gatherer; but so far from there being a general assent in all countries to his maxims as to the expediency of avoiding taxation, which takes more from the tax-payer than what comes into the hands of the government, this is the very characteristic of duties deliberately imposed by most governments for the purpose of interfering with trade, and frequently called for even in the United Kingdom with a similar object. In a question of taxation. however, for the purpose of meeting the expenses of the government, all such duties must be ruled out. Taxes, as instruments for advancing the prosperity of a country, are things unknown to the study of "taxation" in the proper sense of the word. The only proper object of taxation is to meet the expenses of the state, and when taxes are used primarily or mainly for some other object they can only be justified by political and economic reasons of a different order from anything that has been under discussion.

On this ground, in an account of taxation proper, one might avoid discussing altogether the question of irregular or illegitimate taxation. But the subject is of too much popular interest, perhaps, to be passed over altogether. Generally, then, it may be affirmed that taxation in its essential nature cannot be thought of as a good instrument for promoting trade and the advancement of a country. So far as it operates at all, it operates by diverting trade from the channels in which it would naturally flow into other channels, and this diversion of industry, so far as it goes, must involve loss. People are induced to do things they would otherwise leave alone, or to leave alone what they would otherwise do, because money is given to them out of the pockets of the tax-payers to make it worth their while to do so; but there is palpably loss and not profit in the proceeding. It is urged that in time industries are set up that would not otherwise have existed, and population thereby attracted, this being especially the argument for protective duties in new countries; but even so, there is loss to set against the final gain, if any, and we have not yet had an account in which a balance of loss and gain is attempted. The presumption is that on balance there is loss. In new countries especially the diversion of industry from its natural development cannot but be mischievous, wrong manufactures and industries being set up at the expense of the whole community, instead of those manufactures and industries which would be most profitable.

There is more to be said for the political argument which induced Adam Smith to favour navigation laws, giving a preference to national shipping in national waters, and for a similar political argument in favour of duties on agricultural produce imported into the country, on the ground, as regards navigation, that the prosperity of the shipping industry in particular was essential to the safety of the country, and on the ground, as regards duties on agricultural produce, that the maintenance of a larger rural population and of a larger agricultural production than would exist under natural conditions of perfect free trade was essential to the welfare of the state and even to its very existence in the possible event of a temporary defeat at sea and a partial blockade of the coasts. This is not the place to discuss such political problems, but there is no question of free trade theory involved if the cost to the community of any such taxation is frankly acknowledged.

Sir John A. Macdonald, the great protectionist prime minister of Canada, in a conversation with the present writer in 1882, avowed without hesitation that protectionist taxation in Canada was indefensible on economic grounds, and he defended it exclusively for political reasons. Politically one might differ from him, but economists as such must either be silent when political reasons are alleged for taxes that are against fundamental maxims, or must be content to point out the cost of the taxes in order that the communities concerned may decide whether the object in view is obtainable by means of the taxation, and is worth the price.

A great deal has been said as to taxes termed "countervailing duties," which are called for in order to defend free trade itself against the protectionist bounties of foreign governments. Such duties are obviously taxes outside the limits to be considered in a question of taxation proper. They are to be imposed for other purposes than revenue. As to the claim for them that they will restore free trade conditions by nullifying the foreign bounties which have caused a disturbance of trade, this is really in the nature of a political reason. A country which is so devoted to free trade that it not only practises free trade itself but endeavours to convert others by nullifying their protectionist measures as far as it can, even with immediate loss to itself, departs from the guidance of self-interest so far; but its political action may be justifiable in the long run by other considerations. It seems right to point out, however, that countervailing duties, which are really differential duties of a special kind, are not the good expedient they are supposed to be for nullifying foreign bounties; that experience of differential duties in former times is altogether against them; and that they cannot be enforced without certificates of origin and other causes of harassment and confusion in the conduct of trade.

The extent of the interference with trade, in regard to particular taxes, is also a matter of importance. A particular tax is not necessarily to be condemned because it takes a little more out of the pockets of the people than what the government receives. Such a defect is a ground for consideration in weighing a particular tax against others, but it is only one inconvenience among many incidental to all taxes.

Some English applications of free trade theory in recent times in the matter of import duties have been pedantic—the abolition of the shilling corn duty in 1869 by Robert Lowe (Lord Sherbrooke) being typical of this pedantry, though it is not the only instance. No doubt, in theory, this duty, being levied on the import only and not on the home production of corn, took from the tax-payer a shilling on every quarter of grain produced at home which did not go into the exchequer. *Per contra* the tax was wholly unfelt, a shilling a quarter only affecting an average family of four persons to the extent of three shillings per annum, or about three farthings a week, while it was paid little by little, as Adam Smith explains with regard to indirect taxes in general. The amount yielded, moreover, was considerable, being equal to a penny on the income tax, which it is desirable to maintain as a reserve of taxation. When we balance advantages and disadvantages, therefore, the repeal of the corn duty and similar measures would appear to have been sacrifices of revenue without adequate reason.

Rates of Taxation.—Apart from the merits or demerits of particular taxes or groups of taxes, and the questions as to inequality, injury to trade, and the like already discussed, the aggregate of taxation, or rather revenue, of a state may be considered in the most general way, having regard to the proportion appropriated by the state of the total income of the community, and the return made by the state therefor. Here there are the greatest variations. At one time, for instance, during the great wars at the beginning of the 19th century, it was calculated that the British government expenditure, and the corresponding revenue, mostly raised by taxation, were each equal to about one-third of the aggregate of individual incomes—that is, as £90,000,000 to about £270,000,000. Proportions even higher have not been unknown in history, and it is probable that in Russia, India, Egypt, and in other countries at this moment, in time of peace, the proportion may amount to one-fourth or one-fifth. On the other hand, some years ago in the United Kingdom, before the high expenditure on army and navy began, and before the South African war of 1899–1902, it is probable that with an outlay of less than £100,000,000 by the central government, the proportion of this outlay to the aggregate income of the people was not higher than *one-fourteenth.* At the beginning of 1902, when the South African war was closing, the normal peace expenditure, even reckoned at £160,000,000, did not exceed *one-tenth*, while even peace and war expenditure together in 1901, taking them as close on £200,000,000, did not exceed *one-eighth.* These varying proportions, however, mean different things economically, and it is of obvious interest that, besides questions as to particular taxes, the broad effect of the whole burden of taxation should also be discussed.

The important points in this connexion appear to be: (1) Very large appropriations can be made by the state from the revenue of its subjects without *permanent* injury. The community thereby suffers, but the land and fixed capital remain, and when the high government expenditure ceases individuals at once have the benefit, subject to possible disturbance at the moment of transition, when many persons employed by the state return to private employment. (2) A state which in ordinary times appropriates one-tenth or some less proportion of aggregate individual incomes is much stronger relatively than a state absorbing one-fourth, one-third, or even a higher proportion. It has much larger resources, which would be available if time were given to develop them. (3) When the proportion becomes one-tenth or less it is doubtful whether the state can do best for its subjects by making the proportion still lower, that is, by abandoning one tax after another, or whether equal or greater advantage would not be gained by using the revenue for wise purposes under the direction of the state, such as great works of sanitation, or water supply, or public defence. In other words, when taxes are very moderate and the revenue appropriated by the state is a small part only of the aggregate of individual incomes, it seems possible that individuals in a rich country may waste individually resources which the state could apply to very profitable purposes. The state, for instance, could perhaps more usefully engage in some great works, such as establishing reservoirs of water for the use of town populations on a systematic plan, or making a tunnel under one of the channels between Ireland and Great Britain, or a sea-canal across Scotland between the Clyde and the Forth, or purchasing land from Irish landlords and transferring it to tenants, than allow money to fructify or not fructify, as the case may be, in the pockets of individuals. Probably there are no works more beneficial to a community in the long run than those like a tunnel between Ireland and Great Britain, which open an entirely new means of communication of strategical as well as commercial value, but are not likely to pay the individual *entrepreneur* within a short period of time.

GN.)

TAXIDERMY, the art of preserving the integument, together with the scales, feathers or fur, of animals. Little is known of the beginnings of the practice of the "stuffing" or "setting up" of animals for ornament or for scientific purposes; and it is highly probable, from what we gather from old works of travel or natural history, that the art is not more than some three hundred years old. It was practised in England towards the end of the 17th century, as is proved by the Sloane collection, which in 1725 formed the nucleus of the collection of natural history now lodged in the galleries at South Kensington.

It was not until the middle of last century that any treatise devoted to the principles of the then little understood art was published in France, R. A. F. Réaumur's treatise (1749) being probably the first. This was followed at intervals by others in France and Germany, until the beginning of the 19th century, when the English began to move in the matter, and several works were published, notably those by E. Donovan,[1] W. Swainson,[2] Capt. Thomas Brown[3] and others. These works, however, are long since inadequate; and at the Great Exhibition of 1851, the Germans and French taught British taxidermists the rudiments of scientific treatment of natural objects. The demands of sportsmen for the due preservation of their trophies, and the requirements of the great museums in every civilized country, have rapidly transformed a crude handicraft into an elaborate art, and the finest modern results, as produced by a private firm like Rowland Ward in England, or the expert staff of the American Museum of Natural History in New York, leave almost nothing to be desired. The rapidly recurring editions of Rowland Ward's handbook[4] supply a guide to the amateur specially useful as indicating what may be done in the field; John Rowley's little manual[5] supplies

more detail as to what may be done in the workshop; Montague Browne's elaborate treatise[1] remains a standard work, whilst William T. Hornaday[2] has supplied a very full account of the excellent American methods which he has done so much to develop.

The first principle governing the art is that, after the specimen has been procured, in as fresh and clean a state as may be, it should have the skin stripped from the body in such a manner as not to disturb the scales if a fish or a reptile, the feathers if a bird, or the fur or hair if a mammal. To do this correctly requires a small stock of tools, as well as a great amount of patience and perseverance. The appliances comprise several sharp knives (some pointed and some obtuse), a pair of scissors, a pair of pliers, a pair of nippers or "cutting-pliers," some tow, wadding, needles and thread, also a "stuffing-iron," some crooked awls, a pair of fine long flat-nosed pliers, and a camel-hair brush. The preservative compound is often the original (Bécoeur's) "arsenical soap," made by cutting up and boiling 2 ℔ of white soap, to which 12 oz. of salt of tartar and 4 oz. of powdered lime (or whiting) are added when dissolved; to this mixture, when nearly cold, 2 ℔ of powdered arsenic and 5 oz. of camphor (the latter previously triturated in a mortar with spirits of wine) are added. The mixture is put away in small jars or pots for use. Like all arsenical preparations, this is exceedingly dangerous in the hands of unskilled persons, often causing shortness of breath, sores, brittleness of the nails and other symptoms; and, as arsenic is really no protection against the attacks of insects, an efficient substitute has been invented by Browne, composed of 1 ℔ of white curd soap and 3 ℔ of whiting boiled together, to which is added, whilst hot, 1½ oz. of chloride of lime, and, when cold, 1 oz. of tincture of musk. This mixture is perfectly safe to use when cold (although when hot the fumes should not be inhaled, owing to the chlorine given off), and is spoken of as doing its work efficiently. Solutions of corrosive sublimate, often recommended, are, even if efficient, dangerous in the extreme. Powders consisting of tannin, pepper, camphor, and burnt alum are sometimes used for "making skins," but they dry them too rapidly for the purposes of "mounting." Mammals are best preserved by a mixture of 1 ℔ of burnt alum to ¼ ℔ of saltpetre; this, when intimately mixed, should be well rubbed into the skin. Fishes and reptiles, when not cast and modelled, are best preserved in rectified spirits of wine; but this, when economy is desired, can be replaced by "Müller's solution" (bichromate of potash 2 oz., sulphate of soda 1 oz., distilled water 3 pints) or by a nearly saturated solution of chloride of zinc. The cleaning of feathers and furs is performed by rubbing them lightly with wadding soaked in benzoline, afterwards dusting on plaster of Paris, which is beaten out, when dry, with a bunch of feathers.

The preparation and mounting of bird specimens, the objects most usually selected by the amateur, are performed in the following manner. The specimen to be operated upon should have its nostrils and throat closed by plugs of cotton-wool or tow; both wing-bones should be broken close to the body, and the bird laid upon a table on its back; and, as birds—especially white-breasted ones—should seldom, if ever, be opened on the breast, an incision should be made in the skin under the wing on the side most damaged, from which the thigh protrudes when pushed up slightly; this is cut through at its junction with the body, when the knife is gently used to separate the skin from this, until the wing-bone is seen on the open side. This is then cut through by scissors, and by careful manipulation the skin is further freed from the back and breast until the neck can be cut off. The other side now remains to be dealt with; from this the wing is cut by travelling downwards, the remaining leg is cut away, and very careful skinning over the stomach and upon the lower back brings the operator to the tail, which is cut off, leaving a small portion of the bone (the coccyx) in the skin. The body now falls off, and nothing remains in the skin but the neck and head. To skin these out properly without unduly stretching the integument, is a task trying to the patience, but it can be accomplished by gradually working the skin away from the back of the head forward, taking care to avoid cutting the eyes or the eyelids, but by cautious management, to cut the membranous skin over those parts, so that the eyes are easily extracted from the orbits without bursting. The skin should be freed down nearly to the beak, and then the back of the head, with neck attached, should be cut off, the brains extracted, all the flesh cleared from the skull and from the bones of the wings, legs and tail, the skin painted with the preservative, and ultimately turned into its proper position. When "skins" only are to be made for the cabinet, it is sufficient to fill the head and neck with chopped tow, the body with a false one made of tow, tightly packed or loose according to the genius of the preparer, to sew up the skin of the stomach, and to place a band of paper lightly pinned around the body over the breast and wings, and allow it to remain in a warm position, free from dust, for several days or weeks, according to the size of the specimen. It should then be labelled with name, sex, locality and date, and put away with insect powder around it.

When, however, the specimen is to be "mounted," the operations should be carried up to the point of returning the skin, and then a false body of tightly wrapped tow is made upon a wire pointed at its upper end. This is inserted through the incision under the wing, the pointed end going up the neck and through the skull to the outside. When the imitation body rests within the skin, pointed wires are thrust through the soles of the feet, up the skin of the back of the legs, and are finally clenched in the body. Wires are also thrust into the butts of the wings, following the skin of the under surface, and also clenched through into the body. A stand or perch is provided, and the bird, being fixed upon this, is, after the eyes have been inserted, arranged in the most natural attitude which the skill of the taxidermist can give it.

Mammals are cut along the stomach from nearly the middle to the breast, and are skinned by working out the hind legs first, cutting them off under the skin at the junction of the femur with the tibia, and carefully stripping the skin off the lower back and front until the tail is reached, the flesh and bones of which are pulled out of the skin, leaving the operator free to follow on up the back and chest until the fore legs are reached, which are cut off in like manner. The neck and head are skinned out down to the inner edges of the lips and nose, great care being exercised not to cut the outer portions of the ears, the eyelids, the nose or the lips. The flesh being cleared off, and the brain and eyes extracted, the skull should adhere to the skin by the inner edges of the lips. All the flesh should be trimmed from the bones of the legs. The head, being shaped, where the flesh was removed, by tow and clay, is returned into the skin. A long wire of sufficient strength is tightly bound with tow, making a long, narrow body, through which wires are thrust by the skin of the soles of the feet. The leg wires and bones being wrapped with tow and clay into shape, the points of the wires are pushed through the tow body and clenched. They and the body are then bent into the desired position, and modelled up by the addition of more tow and clay, until the contours of the natural body are imitated, when the stomach is sewn up. A board is provided upon which to fix the specimen, artificial eyes are inserted, the lips, nose and eyelids fixed by means of pins or "needle-points," and the specimen is then placed in a warm situation to dry.

Reptiles, when small, have their skin removed by cutting away the attachment of the skull to the cervical vertebrae, and by turning the decapitated trunk out at the mouth by delicate manipulation. When large, they are cut along their median line, and treated in the same manner as mammals.

Fishes, after being covered on their best side with paper or muslin to protect the scales, are cut along the other side from the tail to the gills, and are skinned out by removing "cutlets," as large as is possible without cracking the skin, which, indeed, should be kept damp during work. After being cured with a preservative, they are filled with sawdust or dry plaster of Paris, sewn up, turned over on a board, the fins pinned out, and the mouth adjusted, and, when perfectly dry, the plaster may be shaken out.

The new school of taxidermists, with new methods, whose aim is to combine knowledge of anatomy and modelling with taxidermic technique, has now come to the front, all processes of "stuffing" have been discarded in favour of modelling. Within the limits of an article like the present it is impossible to do more than glance at the intricate processes involved in this. In the case of mammals, after the skin has been completely removed, even to the toes, a copy is made of the body, posed as in life, and from this an accurate representation of form, including delineation of muscles, &c., is built up in light materials, and known as the "manikin"; the model is then covered with skin, which is damped, and moulded to follow every depression and prominence, the manikin, before having the skin put on it, frequently being covered completely with a thin layer of clay; the study is then suffered to dry; and, models having been made, in the case of large animals, of the

[1] *Artistic and Scientific Taxidermy and Modelling* (London, 1896).
[2] *Taxidermy and Zoological Collecting* (London, seventh edition, 1901).

mucous membrane of the jaws, palate, tongue and lips, these are truthfully reproduced in a plastic material. The ordinary glass eyes are discarded, and hollow globes, specially made, are hand-painted from nature, and are fixed in the head so as to convey the exact expression which the pose of the body demands. Birds, if of any size, can be modelled in like manner, and fishes are treated by a nearly identical process, being finally coloured as in a "still life" painting.

To give a life-like representation, attention is also paid to artistic "mounting." By this is meant the surrounding of specimens with appropriate accessories, and it is well exemplified by the work shown in the natural history museum at South Kensington, where, for example, birds are arranged as in a state of nature.

The great American museums have extended a similar method to the mounting of even large mammals, whilst they have made bird groups naturally still more life-like by panoramic backgrounds and top and side lighting of the cases. (M. B.)

TAY, the longest river in Scotland. From its source in Ben Lui (3708 ft.), a mountain on the borders of Perthshire and Argyllshire, it pursues a mainly north-easterly direction to Logierait, where it curves to the south by east as far as Dunkeld; there its course turns to the south-east to the mouth of the Isla, where it bends towards the south by west to the vicinity of Scone. From this point it makes a sharp descent to the south by east beyond the county town, when it sweeps south-east to near Newburgh in Fifeshire, where it again faces the north-east as far as Broughty Ferry, whence it flows straight eastwards into the North Sea, off Buddon Ness in Forfarshire, after a total run of 117 miles. During the first 11 miles it is known as the Fillan and discharges into Loch Dochart. From the lake it emerges as the Dochart (13 m.), which enters Loch Tay at Killin. Flowing through the loch for 14½ m., it issues at Kenmore under its proper name of Tay. From hence to the sea its course measures 78½ m., from which we may deduct 25 m. as the length of the Firth of Tay (which begins at Cairniepier Ferry), leaving 53½ m. as the length of the stream between Kenmore and the mouth of the Earn. Its principal affluents on the right are the Bran, Almond and Earn, and on the left the Lyon, Tummel and Isla. Along with its tributaries, therefore, it drains all Perthshire and portions of Forfarshire and Argyllshire, having a catchment basin of 2400 sq. m. In many parts the current is impetuous, and in flood has occasionally wrought much havoc, certain of the inundations being historically important. Its mean discharge of water every minute is estimated to amount to 273,000 cubic ft., a larger outpour than that of any other stream in the United Kingdom. Vessels make Dundee at all stages of the tide, and the estuary is navigable to Newburgh by vessels of 500 tons, and as far as Perth by ships of 200 tons. The navigation, however, is seriously obstructed by shifting sandbanks. The estuary varies in width from ½ m. at Cairniepier Ferry to fully 3 m. at its mouth. The principal points on the river are Crianlarich on the Fillan (with stations on the West Highland and Callander to Oban railways), Luib and Killin on the Dochart, Kenmore, Aberfeldy, Dunkeld, Birnam, Stanley, Scone, Perth and, on the north shore of the firth, Errol, Dundee, Broughty Ferry and Monifieth, and, on the south shore, Newburgh, Newport and Tayport. It is bridged at Kenmore, Aberfeldy, Logierait, Dunkeld, Caputh and Perth (3). The first railway viaduct across the firth at Dundee was nearly two miles long and had been in use for some eighteen months from the date of its opening in 1877. During the night of the 28th of December 1879, however, while a great gale was at the height of its fury, the passing of a train over the central section gave purchase to the tempest and that portion of the structure was blown down along with the train and the unfortunate travellers. Some 75 to 90 persons are supposed to have perished. The second bridges of somewhat lower height, 2 m. and 73 yds. in length, was erected 60 ft. higher up stream and opened in 1887. The Tay is famous for salmon, the annual catch in the river and estuary being the most valuable in Scotland. There is a hatchery at Hormontfield, close to Luncarty station, 4 m. N. of Perth, for the artificial breeding of salmon, the fish being liberated from the ponds about the age of three years. In respect of riparian scenery the Tay as a whole is the most beautiful river in Scotland, the stretch between Logierait and Cargill, particularly the reaches above and below Dunkeld, being universally admired.

TAY, LOCH, the largest lake in Perthshire, Scotland. It is situated about the middle of the county and has a flattened ogee form, with a general trend from N.E. to S.W. It is 14½ m. long from Killin at the head to Kenmore at the foot, from ½ m. to fully 1 m. wide. The maximum depth is 508 ft., the mean depth 200 ft. The lake lies 355 ft. above the sea, covers an area of 6550 acres, or over 10 sq. m., and has a drainage basin of 232 sq. m., including the overflow from Lochs Dochart and Tubhair. It receives at Killin the rivers Lochay and Dochart and discharges by the Tay at Kenmore. Ben Lawers (3984 ft.) rises near the left bank. There are piers at Killin, Ardeonaig, Lawers, Fernan and Kenmore, at which the steamers call during the tourist season; ferries at Ardeonaig and Lawers; and a coaching road on the left shore and a somewhat longer and more hilly road on the right. At the foot of the lake is an island containing the ruins of the priory which was founded in 1121 by Alexander I. in memory of his wife Sibylla, daughter of Henry I. She was buried here. Loch Tay enjoys great repute for its salmon-fishing.

TAYABAS, a town of the province of Tayabas, Luzon, Philippine Islands, 8 m. N. of Lucena, the capital. Pop. of the municipality (1903) 14,740. Tayabas is picturesquely situated on the slopes of the extinct volcano Banájao, and commands a magnificent view of the surrounding country, which is extremely fertile, and is planted in rice and coco-nuts. Its climate, although cool, is very unhealthy, malignant malarial fevers causing a high death-rate. It has a church and convent of large size and massive construction. During the revolt of 1896 a Spanish garrison occupying these buildings withstood a siege of fifty-eight days, at the end of which time it was forced to surrender by lack of food. Tagalog and Bicol are the languages spoken. Until 1901 Tayabas was the capital of the province.

TAYGETUS (*Ταΰγετος* or *Ταΰγετον*, mod. St Elias or Pentedaktylon), the highest mountain ridge in the Peloponnese, separating Laconia from Messenia. Height 7900 ft. The highest point is H. Elias; here horses are said to have been sacrificed to Helios.

TAYLOR, ANN (1782–1866), afterwards Mrs. Gilbert, and **TAYLOR, JANE** (1783–1824), English writers for children, daughters of Isaac Taylor (1759–1829), were born in London on the 30th of January 1782 and the 23rd of September 1783 respectively. In 1786 the Taylors went to live at Lavenham in Suffolk, and ten years later removed to Colchester. Jane was a lively and entertaining child, and composed plays and poems at a very early age. Their father and mother held advanced views on education, and under their guidance the girls were instructed not only in their father's art of engraving, but in the principles of fortification. Their poems were written in short intervals in the round of each day's occupations. Ann introduced herself to the publishers Darton and Harvey by a rhymed answer to a puzzle in the *Minor's Pocket Book* for 1799, and Jane made her first appearance in print in the same periodical with "The Beggar Boy." The publishers then wrote to Isaac Taylor asking for more verses for children from his family, and the result was *Original Poems for Infant Minds* (2 vols., 1804–5), by "several young persons," of whom Ann and Jane were the largest contributors. The book had an immediate and lasting success. It went through numerous editions, and was translated into German, Dutch and Russian. Ann and Jane Taylor wrote directly for children, and viewed events and morals from the nursery standpoint. They had many imitators, but few serious rivals in their own kind, except perhaps Mrs Elizabeth Turner. They followed up this success with *Rhymes for the Nursery* (1806), *Hymns for Infant Minds* (1808, 2nd ed. 1810), a less-known collection, *Signor Topsy*

Turvy's Wonderful Magic Lantern; or, The World Turned Upside Down (1810), and *Original Hymns for Sunday School* (1812). In 1813 Ann married a Congregational minister, the Rev. Josiah Gilbert, and Jane went to live at Ilfracombe with her brother Isaac. In 1816 Jane returned to Ongar, where the family had been settled for some years, and died there on the 13th of April 1824. Mrs Gilbert died at Nottingham on the 20th of December 1866. Both sisters wrote after their separation, but none of their later works had the same vogue. Jane showed more wit and vivacity than her sister, notably in the *Contributions of Q. Q.* (2 vols., 1824), and in *Display, a Tale for Young People* (1815); but, though she was generally supposed to be the chief writer of the two, some of the most famous pieces in their joint works, such as "I thank the goodness and the grace," "Meddlesome Matty," "The Notorious Glutton," &c., are by Ann.

The best edition of the *Poetical Works* of the sisters is that of 1877. There is an excellent edition (1903) of the *Original Poems and Others*, by Ann and Jane Taylor and Adelaide O'Keeffe, edited by E. V. Lucas, with illustrations by F. D. Bedford.

Abundant information about Ann and Jane Taylor is to be found in: *Autobiography and Other Memorials of Mrs Gilbert* (2 vols., 1874), edited by her son Josiah Gilbert; Isaac Taylor, *Memoirs . . . of Jane Taylor* (2 vols., 1825), and the collection by the same editor entitled *The Family Pen: Memorials . . . of the Taylor Family of Ongar*, vol. ii. (1867).

TAYLOR, BAYARD (1825–1878), American author, was born at Kennett Square in Chester county, Pennsylvania, on the 11th of January 1825. The son of a well-to-do farmer, he received his early instruction in an academy at West Chester, and later at Unionville. At the age of seventeen he was apprenticed to a printer in West Chester. A little volume, published at Philadelphia in 1844 under the title *Ximena, or the Battle of the Sierra Morena, and other Poems*, brought its author a little cash; and indirectly it did him better service as the means of his introduction to *The New York Tribune*. With the money thus obtained, and with an advance made to him on account of some journalistic work to be done in Europe, "J. B. Taylor" (as he had up to this time signed himself, though he bore no other Christian name than Bayard) set sail for the East. The young poet spent a happy time in roaming through certain districts of England, France, Germany and Italy; that he was a born traveller is evident from the fact that this pedestrian tour of almost two years cost him only £100. The graphic accounts which he sent from Europe to *The New York Tribune*, *The Saturday Evening Post*, and *The United States Gazette* were so highly appreciated that on Taylor's return to America he was advised to throw his articles into book form. In 1846, accordingly, appeared his *Views Afoot, or Europe seen with Knapsack and Staff* (2 vols., New York). This pleasant book had considerable popularity, and its author now found himself a recognized man of letters; moreover, Horace Greeley, then editor of the *Tribune*, placed Taylor on the *Tribune* staff (1848) thus securing him a certain if a moderate income. His next journey, made when the gold-fever was at its height, was to California, as correspondent for the *Tribune;* from this expedition he returned by way of Mexico, and, seeing his opportunity, published (2 vols., New York, 1850) a highly successful book of travels, entitled *El Dorado; or, Adventures in the Path of Empire*. Ten thousand copies were said to have been sold in America, and thirty thousand in Great Britain, within a fortnight from the date of issue. Bayard Taylor always considered himself native to the East, and it was with great delight that in 1851 he found himself on the banks of the Nile. He ascended as far as 12° 30′ N., and stored his memory with countless sights and delights, to many of which he afterwards gave expression in metrical form. From England, towards the end of 1852, he sailed for Calcutta, proceeding thence to China, where he joined the expedition of Commodore Perry to Japan. The results of these journeys (besides his poetical memorials) were *A Journey to Central Africa; or, Life and Landscapes from Egypt to the Negro Kingdoms of the White Nile* (New York, 1854); *The Lands of the Saracen; or, Pictures of Palestine, Asia Minor, Sicily and Spain* (1854); and *A Visit to India, China and Japan in the Year 1853* (1855). On his return (December 20, 1853) from these various journeyings he entered, with marked success, upon the career of a public lecturer, delivering addresses in every town of importance from Maine to Wisconsin. After two years' experience of this lucrative profession, he again started on his travels, on this occasion for northern Europe, his special object being the study of Swedish life, language and literature. The most noteworthy result was the long narrative poem *Lars*, but his "Swedish Letters" to the *Tribune* were also republished, under the title *Northern Travel: Summer and Winter Pictures* (London, 1857). His first wife, May Agnew, died (1850) within a year of her marriage, and in October 1857 he married Maria Hansen, the daughter of Peter Hansen, the German astronomer. The ensuing winter was spent in Greece. In 1859 Taylor once more traversed the whole extent of the western American gold region, the primary cause of the journey lying in an invitation to lecture at San Francisco. About three years later he entered the diplomatic service as secretary of legation at St Petersburg, and the following year (1863) became chargé d'affaires at the Russian capital. In 1864 he returned to the United States and resumed his active literary labours, and it was at this period that *Hannah Thurston* (New York, 1863), the first of his four novels, was published. This book had a moderate success, but neither in it nor in its successors did Bayard Taylor betray any special talent as a novelist. In 1874 he went to Iceland, to report for the *Tribune* the one thousandth anniversary of the first settlement there. In June 1878 he was accredited United States minister at Berlin. Notwithstanding the resistless passion for travel which had always possessed him, Bayard Taylor was (when not actually *en route*) sedentary in his habits, especially in the later years of his life. His death occurred on the 19th of December, only a few months after his arrival in Berlin.

Taylor's most ambitious productions in poetry—his *Masque of the Gods* (Boston, 1872), *Prince Deukalion; a lyrical drama* (Boston, 1878), *The Picture of St John* (Boston, 1866), *Lars; a Pastoral of Norway* (Boston, 1873), and *The Prophet; a tragedy* (Boston, 1874)—are marred by a ceaseless effort to overstrain his power. But he will be remembered by his poetic and excellent translation of *Faust* (2 vols., Boston, 1870–71) in the original metres. Taylor felt, in all truth, "the torment and the ecstasy of verse"; but, as a critical friend has written of him, "his nature was so ardent, so full-blooded, that slight and common sensations intoxicated him, and he estimated their effect, and his power to transmit it to others, beyond the true value." He had, from the earliest period at which he began to compose, a distinct lyrical faculty: so keen indeed was his ear that he became too insistently haunted by the music of others, pre-eminently of Tennyson. But he had often a true and fine note of his own. His best short poems are "The Metempsychosis of the Pine" and the well-known Bedouin love-song. In his critical essays Bayard Taylor had himself in no inconsiderable degree what he wrote of as "that pure poetic insight which is the vital spirit of criticism." The most valuable of these prose dissertations are the *Studies in German Literature* (New York, 1879). Collected editions of his *Poetical Works* and his *Dramatic Works* were published at Boston in 1888; his *Life and Letters* (Boston, 2 vols., 1884) were edited by his wife and Horace E. Scudder.

TAYLOR, BROOK (1685–1731), English mathematician, was the son of John Taylor, of Bifrons House, Kent, by Olivia, daughter of Sir Nicholas Tempest, Bart., of Durham, and was born at Edmonton in Middlesex on the 18th of August 1685. He entered St John's College, Cambridge, as a fellow-commoner in 1701, and took degrees of LL.B. and LL.D. respectively in 1709 and 1714. Having studied mathematics under John Machin and John Keill, he obtained in 1708 a remarkable solution of the problem of the "centre of oscillation," which, however, remaining unpublished until May 1714 (*Phil. Trans.*, vol. xxviii. p. 11), his claim to priority was unjustly disputed by John Bernoulli. Taylor's *Methodus Incrementorum Directa et Inversa* (London, 1715) added a new branch to the higher mathematics, now designated the "calculus of finite differences." Among other ingenious applications, he used it to determine the form of movement of a vibrating string, by him first successfully reduced to mechanical principles. The same work contained the celebrated formula known as "Taylor's theorem" (see INFINITESIMAL CALCULUS), the importance of which remained unrecognized until 1772, when J. L. Lagrange realized its powers and termed it "*le principal fondement du calcul différentiel.*"

In his essay on *Linear Perspective* (London, 1715) Taylor set forth the true principles of the art in an original and more general form than any of his predecessors; but the work suffered from the brevity and obscurity which affected most of his writings, and needed the elucidation bestowed on it in the treatises of Joshua Kirby (1754) and Daniel Fournier (1761).

Taylor was elected a fellow of the Royal Society early in 1712, sat in the same year on the committee for adjudicating the claims of Sir Isaac Newton and Gottfried Wilhelm Leibnitz, and acted as secretary to the society from the 13th of January 1714 to the 21st of October 1718. From 1715 his studies took a philosophical and religious bent. He corresponded, in that year, with the Comte de Montmort on the subject of Nicolas Malebranche's tenets; and unfinished treatises, "On the Jewish Sacrifices" and "On the Lawfulness of Eating Blood," written on his return from Aix-la-Chapelle in 1719, were afterwards found among his papers. His marriage in 1721 with Miss Brydges of Wallington, Surrey, led to an estrangement from his father, a person of somewhat morose temper, which terminated in 1723 after the death of the lady in giving birth to a son. The ensuing two years were spent by him with his family at Bifrons, and in 1725 he married, with the paternal approbation, Sabetta, daughter of Mr Sawbridge of Olantigh, Kent, who, by a strange fatality, died also in childbed in 1730; in this case, however, the infant, a daughter, survived. Taylor's fragile health gave way; he fell into a decline, died on the 29th of December 1731, at Somerset House, and was buried at St Ann's, Soho. By his father's death in 1729 he had inherited the Bifrons estate. As a mathematician, he was the only Englishman after Sir Isaac Newton and Roger Cotes capable of holding his own with the Bernoullis; but a great part of the effect of his demonstrations was lost through his failure to express his ideas fully and clearly.

A posthumous work entitled *Contemplatio Philosophica* was printed for private circulation in 1793 by his grandson, Sir William Young, Bart., prefaced by a life of the author, and with an appendix containing letters addressed to him by Bolingbroke, Bossuet, &c. Several short papers by him were published in *Phil. Trans.*, vols. xxvii. to xxxii., including accounts of some interesting experiments in magnetism and capillary attraction. He issued in 1719 an improved version of his work on perspective, with the title *New Principles of Linear Perspective*, revised by Colson in 1749, and printed again, with portrait and life of the author, in 1811. A French translation appeared in 1753 at Lyons. Taylor gave (*Methodus Incrementorum*, p. 108) the first satisfactory investigation of astronomical refraction.

TAYLOR, SIR HENRY (1800–1886), English poet and political official, was born on the 18th of October 1800, at Bishop-Middleham, Durham, where his ancestors had been small landowners for some generations. His mother died while he was yet an infant, and he was chiefly educated by his father, a man of studious tastes, who, finding him less quick than his two elder brothers, allowed him to enter the navy as a midshipman. Finding the life uncongenial, he only remained eight months at sea, and after obtaining his discharge was appointed to a clerkship in the storekeeper's office. He had scarcely entered upon his duties when he was attacked by typhus fever, which carried off both his brothers, then living with him in London. In three or four years more his office was abolished while he was on duty in the West Indies. On his return he found his father happily married to a lady whose interest and sympathy proved of priceless value to him. Through her he became acquainted with her cousin, Isabella Fenwick, the neighbour and intimate friend of Wordsworth, who introduced him to Wordsworth and Southey. Under these influences he lost his early admiration for Byron, whose school, whatever its merits, he at least was in no way calculated to adorn, and his intellectual powers developed rapidly. In October 1822 he published an article on Moore's *Irish Melodies* in the *Quarterly Review*. A year later he went to London to seek his fortune as a man of letters, and met with rapid success, though not precisely in this capacity. He became editor of the *London Magazine*, to which he had already contributed, and in January 1824 obtained, through the influence of Sir Henry Holland, a good appointment in the Colonial Office. He was immediately entrusted with the preparation of confidential state papers, and his opinion soon exercised an important influence on the decisions of the secretary of state. He visited Wordsworth and Southey, travelled on the Continent with the latter, and at the same time, mainly through his friend and official colleague, the Hon. Hyde Villiers, became intimate with a very different set, the younger followers of Bentham, without, however, adopting their opinions—"young men," he afterwards reminded Stuart Mill, "who every one said would be ruined by their independence, but who ended by obtaining all their hearts' desires, except one who fell by the way." The reference is to Hyde Villiers, who died prematurely. Taylor actively promoted the emancipation of the slaves in 1833, and became an intimate ally of Sir James Stephen, then counsel to the Colonial Office, afterwards under-secretary, by whom the Act of Emancipation was principally framed. His duties at the Colonial Office were soon afterwards lightened by the appointment of James Spedding, with whom he began a friendship that lasted till the end of his life.

His first drama, *Isaac Comnenus*, Elizabethan in tone, and giving a lively picture of the Byzantine court and people, was published anonymously in 1828. Though highly praised by Southey, it made little impression on the public. *Philip van Artevelde*, an elaborate poetic drama, the subject of which had been recommended to him by Southey, was begun in 1828, published in 1834, and, aided by a laudatory criticism from Lockhart's pen in the *Quarterly*, achieved extraordinary success. Its great superiority to Taylor's other works may be explained by its being to a great extent the vehicle of his own ideas and feelings. Artevelde's early love experiences reproduce and transfigure his own. *Edwin the Fair* (1842) was less warmly received; but his character of Dunstan, the ecclesiastical statesman, is a fine psychological study, and the play is full of historical interest. Meanwhile he had married (1839) Theodosia Spring-Rice, the daughter of his former chief Lord Monteagle, and, in conjunction with Sir James Stephen, had taken a leading part in the abolition of negro apprenticeship in the West Indies. *The Statesman*, a volume of essays suggested by his official position, had been published in 1836, and about the same time he had written in the *Quarterly* the friendly notices of Wordsworth and Southey which did much to dispel the conventional prejudices of the day, and which were published in 1849 under the somewhat misleading title of *Notes from Books*.

In 1847 he was offered the under-secretaryship of state for the colonies, which he declined. *Notes from Life* and *The Eve of the Conquest* appeared in this year; and an experiment in romantic comedy, *The Virgin Widow*, afterwards entitled *A Sicilian Summer*, was published in 1850. "The pleasantest play I had written," says the author; "and I never could tell why people would not be pleased with it." His last dramatic work was *St Clement's Eve*, published in 1862. In 1869 he was made K.C.M.G. He retired from the Colonial Office in 1872, though continuing to be consulted by government. His last days were spent at Bournemouth in the enjoyment of universal respect; and the public, to whom he had hitherto been an almost impersonal existence, became familiarized with the extreme picturesqueness of his appearance in old age, as represented in the photographs of his friend Julia Margaret Cameron. He died on the 27th of March 1886. His *Autobiography*, published a year before his death, while sinning a little by the egotism pardonable in a poet and the garrulity natural to a veteran, is in the main a pleasing and faithful picture of an aspiring youth, an active maturity, and a happy and honoured old age.

Taylor's *Artevelde* cannot fail to impress those who read it as the work of a poet of considerable distinction; but, perhaps for the very reason that he was so prominent as a state official, he has not been accepted by the world as more than a very accomplished man of letters. His lyrical work is in general laboriously artificial, but he produced two well-known songs—"Quoth tongue of neither maid nor wife" and "If I had the wings of a dove."

Taylor's *Autobiography* (2 vols. 1885) should be supplemented by his *Correspondence* (1888), edited by Edward Dowden. His *Works* were collected in five volumes in 1877–78.

TAYLOR, ISAAC (1787–1865), English author, son of Isaac Taylor (1759–1829), engraver and author, was born at Lavenham, Suffolk, on the 17th of August 1787. He was trained by his father to be an engraver, but early adopted literature as a profession. From 1824, the year of his marriage, he lived a busy but uneventful life at Stanford Rivers, near Ongar, Essex, where he died on the 28th of June 1865. His attention was drawn to the study of the fathers of the church through reading the works of Sulpicius Severus, which he had picked up at a bookstall. He published a *History of the Transmission of Ancient Books to Modern Times* (1827), a study in biblical criticism, and some other works, but he attracted little notice until, in 1829, he published anonymously a book bearing upon the religious and political problems of the day, entitled *The Natural History of Enthusiasm*, which speedily ran through eight or nine editions. *Fanaticism* (1833), *Spiritual Despotism* (1835), *Saturday Evening* (1832), and *The Physical Theory of Another Life* (1836), all commanded a large circulation. In his *Ancient Christianity* (1839–46), a series of dissertations in reply to the "Tracts for the Times," Taylor maintained that the Christian church of the 4th century should not be regarded as embodying the doctrine and practice of the apostles because it was then already corrupted by contact with pagan superstition. The book met with great opposition, but Taylor did not follow up the controversy.

Among his other works may be mentioned biographies of Ignatius Loyola (1849) and John Wesley (1851); a volume entitled *The Restoration of Belief* (1855); and a course of lectures on *The Spirit of Hebrew Poetry* (1861).

TAYLOR, ISAAC (1829–1901), English philologist, eldest son of the preceding, was born at Stanford Rivers, 2nd May 1829. He was educated at Trinity College, Cambridge, and took the mathematical tripos in 1853. His interests, however, were linguistic rather than mathematical, and his earliest publication was a translation from the German of W. A. Becker's *Charicles*. Though of Nonconformist stock, Isaac Taylor joined the Church of England, and in 1857 was ordained to a country curacy. In 1860 he published *The Liturgy of the Dissenters*, an appeal for the revision of the Book of Common Prayer "on Protestant lines," "as expedient for the material interests of the Church, and as an act of plain justice to the Dissenters." His studies in local etymology bore fruit in *Words and Places in Etymological Illustration of History, Ethnology and Geography* (1864). Between 1865 and 1869, when he was in charge of a Bethnal Green parish, his philological studies were laid aside, and he published only *The Burden of the Poor* and *The Family Pen*, a record of the literary work of his own family, the Taylors of Ongar. In 1869 he became incumbent of a church at Twickenham, and used his comparative leisure to produce his *Etruscan Researches* (1874), in which he contended for the Ugrian origin of the Etruscan language. In 1875 he was presented to the rectory of Settrington, Yorkshire, and began his systematic researches into the origin of the alphabet. His *Greeks and Goths; a Study on the Runes* (1879), in which he suggested that the runes were of Greek origin, led to a good deal of controversy. His most important work is *The Alphabet, an Account of the Origin and Development of Letters* (1883; new and revised edition 1899). Taylor points out that alphabetical changes are the result of evolution taking place in accordance with fixed laws. "Epigraphy and palaeography may claim, no less than philology or biology, to be ranked among the inductive sciences." He was largely indebted to the Egyptian researches of Rougé, which it has since become necessary to reconside in the light of discoveries in Crete. In 1885 Taylor became canon of York, and two years later dean. His paper on the *Origin of the Aryans*, read at the British Association in 1887, was afterwards expanded into a book. In the following winter he visited Egypt, and his letters from there, collected under the title *Leaves from an Egyptian Notebook*, aroused considerable controversy from the extremely favourable view he took of the Mahommedan religion. For the last few years of his life Dean Taylor suffered from ill health, and was laid aside from active work for some time before his death in October 1901.

TAYLOR, JEREMY (1613–1667), English divine and author, was baptized at Cambridge on the 15th of August 1613. His father, Nathaniel, though a barber, was a man of some education, for Jeremy was "solely grounded in grammar and mathematics" by him. The tradition that he was descended from Dr Rowland Taylor, Cranmer's chaplain, who suffered martyrdom under Mary, is grounded on the untrustworthy evidence of a certain Lady Wray, said to have been a granddaughter of Jeremy Taylor. She supplied Bishop Heber in 1732 with other biographical data of doubtful authenticity. Jeremy Taylor was a pupil of Thomas Lovering, at the newly founded Perse grammar school. Lovering is first mentioned as master in 1619, so that Taylor probably spent seven years at the school before he was entered at Gonville and Caius College as a sizar in 1626,[1] eighteen months after Milton had entered Christ's, and while George Herbert was public orator and Edmund Waller and Thomas Fuller were undergraduates of the university. He was elected a Perse scholar in 1628, and fellow of his college in 1633, but the best evidence of his diligence as a student is the enormous learning of which he showed so easy a command in after years. In 1633, although still below the canonical age, he took holy orders, and, accepting the invitation of Thomas Risden, a former fellow-student, to supply his place for a short time as lecturer in St Paul's, he at once attracted attention by his eloquence and by his handsome face. Archbishop Laud sent for Taylor to preach before him at Lambeth, and took the young man under his special protection. Taylor did not vacate his fellowship at Cambridge before 1636, but he spent, apparently, much of his time in London, for Laud desired that his "mighty parts should be afforded better opportunities of study and improvement than a course of constant preaching would allow of." In November 1635 he had been nominated by Laud to a fellowship at All Souls, Oxford, where, says Wood (*Athen. Oxon.*, Ed. Bliss, iii. 781), love and admiration still waited on him. He seems, however, to have spent little time there. He became chaplain to his patron the archbishop, and chaplain in ordinary to Charles I. At Oxford William Chillingworth was then busy with his great work, *The Religion of Protestants*, and it is possible that by intercourse with him Taylor's mind may have been turned towards the liberal movement of his age. After two years in Oxford, he was presented, in March 1638, by Juxon, bishop of London, to the rectory of Uppingham, in Rutlandshire. In the next year he married Phoebe Langsdale, by whom he had six children, the eldest of whom died at Uppingham in 1642. In the autumn of the same year he was appointed to preach in St Mary's on the anniversary of the Gunpowder Plot, and apparently used the occasion to clear himself of a suspicion, which, however, haunted him through life, of a secret leaning to the Romish communion. This suspicion seems to have arisen chiefly from his intimacy with Christopher Davenport, better known as Francis a Sancta Clara, a learned Franciscan friar who became chaplain to Queen

[1] An obviously erroneous entry in the Admission Book states that he had been at school under Mr. Lovering for ten years, and was in his fifteenth year. *Admissions to Gonville and Caius College* (ed. J. Venn, 1887).

Henrietta; but it may have been strengthened by his known connexion with Laud, as well as by his ascetic habits. More serious consequences followed his attachment to the Royalist cause. The author of *The Sacred Order and Offices of Episcopacy or Episcopacy Asserted against the Aerians and Acephali New and Old* (1642), could scarcely hope to retain his parish, which was not, however, sequestrated until 1644. Taylor probably accompanied the king to Oxford. In 1643 he was presented to the rectory of Overstone, Northamptonshire, by Charles I. There he would be in close connexion with his friend and patron Spencer Compton, 2nd earl of Northampton.

During the next fifteen years Taylor's movements are not easily traced. He seems to have been in London during the last weeks of Charles I., from whom he is said to have received his watch and some jewels which had ornamented the ebony case in which he kept his Bible. He had been taken prisoner with other Royalists while besieging Cardigan castle on the 4th of February 1645. In 1646 he is found in partnership with two other deprived clergymen, keeping a school at Newton Hall, in the parish of Llanvihangel-Aberbythych, Carmarthenshire. Here he became private chaplain to Richard Vaughan, 2nd earl of Carbery (1600–1686), whose hospitable mansion, Golden Grove, is immortalized in the title of Taylor's still popular manual of devotion, and whose first wife was a constant friend of Taylor. The second Lady Carbery was the original of the "Lady" in Milton's *Comus*. Mrs Taylor had died early in 1651. He second wife was Joanna Bridges, said on very doubtful authority to have been a natural daughter of Charles I. She owned a good estate, though probably impoverished by Parliamentarian exactions, at Mandinam, in Carmarthenshire.

From time to time Jeremy Taylor appears in London in the company of his friend Evelyn, in whose diary and correspondence his name repeatedly occurs. He was three times imprisoned: in 1654–5 for an injudicious preface to his *Golden Grove*; again in Chepstow castle, from May to October 1655, on what charge does not appear; and a third time in the Tower in 1657–8, on account of the indiscretion of his publisher, Richard Royston, who had adorned his "Collection of Offices" with a print representing Christ in the attitude of prayer.

Much of his best work was produced at Golden Grove. In 1646 appeared his famous plea for toleration, Θεολογία Ἐκλεκτική, *A Discourse of the Liberty of Prophesying*. In 1649 he published the complete edition of his *Apology for authorized and set forms of Liturgy against the Pretence of the Spirit*, as well as his *Great Exemplar . . . a History of . . . Jesus Christ*, a book which was inspired, its author tells us, by his earlier intercourse with the earl of Northampton. Then followed in rapid succession the *Twenty-seven Sermons* (1651), "for the summer half-year," and the *Twenty-five* (1653), "for the winter half-year," *The Rule and Exercises of Holy Living* (1650), *The Rule and Exercises of Holy Dying* (1651), a controversial treatise on *The Real Presence* . . . (1654), the *Golden Grove; or a Manuall of daily prayers and letanies* . . . (1655), and the *Unum Necessarium* (1655), which by its Pelagianism gave great offence.[1] *The Rule and Exercises of Holy Living* provided a manual of Christian practice, which has retained its place with devout readers. The scope of the work is described on the title-page. It deals with "the means and instruments of obtaining every virtue, and the remedies against every vice, and considerations serving to the resisting all temptations, together with prayers containing the whole Duty of a Christian." *Holy Dying* was perhaps even more popular. A very charming piece of work of a lighter kind was inspired by a question from his friend, Mrs Katherine Phillips (the "matchless Orinda"), asking "How far is a dear and perfect friendship authorized by the principles of Christianity?" In answer to this he dedicated to the "most ingenious and excellent Mrs Katherine Phillips" his *Discourse of the Nature, Offices and Measures of Friendship* (1657). His *Ductor Dubitantium, or the Rule of Conscience* . . . (1660) was intended to be the standard manual of casuistry and ethics for the Christian people.

He probably left Wales in 1657, and his immediate connexion with Golden Grove seems to have ceased two years earlier. In 1658, through the kind offices of his friend John Evelyn, Taylor was offered a lectureship in Lisburn, Ireland, by Edward Conway, second Viscount Conway. At first he declined a post in which the duty was to be shared with a Presbyterian, or, as he expressed it, "where a Presbyterian and myself shall be like Castor and Pollux, the one up and the other down," and to which also a very meagre salary was attached. He was, however, induced to take it, and found in his patron's mansion at Portmore, on Lough Neagh, a congenial retreat.

At the Restoration, instead of being recalled to England, as he probably expected and certainly desired, he was appointed to the see of Down and Connor, to which was shortly added the small adjacent diocese of Dromore. He was also made a member of the Irish privy council and vice-chancellor of the university of Dublin. None of these honours were sinecures. Of the university he writes, "I found all things in a perfect disorder . . . . a heap of men and boys, but no body of a collegé, no one member, either fellow or scholar, having any legal title to his place, but thrust in by tyranny or chance." Accordingly he set himself vigorously to the task of framing and enforcing regulations for the admission and conduct of members of the university, and also of establishing lectureships. His episcopal labours were still more arduous. There were, at the date of the Restoration, about seventy Presbyterian ministers in the north of Ireland, and most of these were from the west of Scotland, and were imbued with the dislike of Episcopacy which distinguished the Covenanting party. No wonder that Taylor, writing to the duke of Ormonde shortly after his consecration, should have said, "I perceive myself thrown into a place of torment.". His letters perhaps somewhat exaggerate the danger in which he lived, but there is no doubt that his authority was resisted and his overtures rejected. His writings also were ransacked for matter of accusation against him, "a committee of Scotch spiders being appointed to see if they can gather or make poison out of them." Here, then, was Taylor's opportunity for exemplifying the wise toleration he had in other days inculcated, but the new bishop had nothing to offer the Presbyterian clergy but the bare alternative—submission to episcopal ordination and jurisdiction or deprivation. Consequently, in his first visitation, he declared thirty-six churches vacant; and of these forcible possesssion was taken by his orders. At the same time many of the gentry were won by his undoubted sincerity and devotedness as well as by his eloquence. With the Roman Catholic element of the population he was less successful. Ignorant of the English language, and firmly attached to their ancestral forms of worship, they were yet compelled to attend a service they considered profane, conducted in a language they could not understand. As Heber says, "No part of the administration of Ireland by the English crown has been more extraordinary and more unfortunate than the system pursued for the introduction of the Reformed religion." At the instance of the Irish bishops Taylor undertook his last great work, the *Dissuasive from Popery* (in two parts, 1664 and 1667), but, as he himself seemed partly conscious, he might have more effectually gained his end by adopting the methods of Ussher and Bedell, and inducing his clergy to acquire the Irish tongue.

The troubles of his episcopate no doubt shortened his life. Nor were domestic sorrows wanting in these later years. In 1661 he buried, at Lisburn, Edward, the only surviving son of his second marriage. His eldest son, an officer in the army, was killed in a duel; and his second son, Charles, intended for the church, left Trinity College and became companion and secretary to the duke of Buckingham, at whose house he died. The day after his son's funeral Taylor caught fever from a patient whom he visited, and, after a ten days' illness, he died at Lisburn on the 13th of August 1667, in the fifty-fifth year of

[1] See an angry letter by Brian Duppa, bishop of Salisbury, on the subject (*Eden* i. xlii.).

his life and the seventh of his episcopate, and was buried in the cathedral of Dromore.

Taylor's fame has been maintained by the popularity of his sermons and devotional writings rather than by his influence as a theologian or his importance as an ecclesiastic. His mind was neither scientific nor speculative, and he was attracted rather to questions of casuistry than to the problems of pure theology. His wide reading and capacious memory enabled him to carry in his mind the materials of a sound historical theology, but these materials were unsifted by criticism. His immense learning served him rather as a storehouse of illustrations, or as an armoury out of which he could choose the fittest weapon for discomfiting on opponent, than as a quarry furnishing him with material for building up a completely designed and enduring edifice of systematized truth. Indeed, he had very limited faith in the human mind as an instrument of truth. "Theology," he says, "is rather a divine life than a divine knowledge." His great plea for toleration is based on the impossibility of erecting theology into a demonstrable science. "It is impossible all should be of one mind. And what is impossible to be done is not necessary it should be done." Differences of opinion there must be; but "heresy is not an error of the understanding but an error of the will." He would submit all minor questions to the reason of the individual member, but he set certain limits to toleration, excluding "whatsoever is against the foundation of faith, or contrary to good life and the laws of obedience, or destructive to human society, and the public and just interests of bodies politic." Peace, he thought, might be made "if men would not call all opinions by the name of religion, and superstructures by the name of fundamental articles." Of the propositions of sectarian theologians he said that confidence was the first, and the second, and the third part. Of a genuine poetic temperament, fervid and mobile in feeling, and of a prolific fancy, he had also the sense and wit that come of varied contact with men. All his gifts were made available for influencing other men by his easy command of a style rarely matched in dignity and colour. With all the majesty and stately elaboration and musical rhythm of Milton's finest prose, Taylor's style is relieved and brightened by an astonishing variety of felicitous illustrations, ranging from the most homely and terse to the most dignified and elaborate. His sermons especially abound in quotations and allusions, which have the air of spontaneously suggesting themselves, but which must sometimes have baffled his hearers. This seeming pedantry is, however, atoned for by the clear practical aim of his sermons, the noble ideal he keeps before his hearers, and the skill with which he handles spiritual experience and urges incentives to virtue.

The whole works of . . . Jeremy Taylor with a life of the author and a critical examination of his writings was published by Bishop Reginald Heber in 1822, reissued after careful revision by Charles Page Eden (1847–54). His most popular works, *The Liberty of Prophesying*, *Holy Living*, and *Holy Dying* have been often reprinted. *The Poems and Verse-translations of Jeremy Taylor* were edited by Dr. A. B. Grosart in vol. i. of the *Miscellanies of the Fuller Worthies Library* (1870). The first biographer of Jeremy Taylor was his friend and successor, George Rust, who preached a funeral sermon (in 1668) which remains a valuable document. His life has been written by John Wheeldon (1793), H. K. Bonney (1815), T. S. Hughes (1831), R. H. Willmott (1847), George L. Duyckinck (New York, 1860). The chief authority is still Eden's revision of Bishop Heber's memoir, which includes much valuable correspondence. See also E. W. Gosse's *Jeremy Taylor* (1904) in the *English Men of Letters* series. A bibliography of works dealing with the subject is included in the article by the Rev. Alexander Gordon in the *Dictionary of National Biography*. S. T. Coleridge was a diligent student and a warm admirer of Jeremy Taylor, whom he regarded as one of the great masters of English style. A series of comments by Coleridge are collected in his *Literary Remains* (1838, vol. iii. pp. 203-390).

TAYLOR, JOHN (1580–1653), English pamphleteer, commonly called the "Water-Poet," was born at Gloucester on the 24th of August 1580. After fulfilling his apprenticeship to a waterman, he served (1596) in Essex's fleet, and was present at Flores in 1597 and at the siege of Cadiz. On his return to England he became a Thames waterman, and was at one time collector of the perquisites exacted by the lieutenant of the Tower. He was an expert in the art of self-advertisement, and achieved notoriety by a series of eccentric journeys. With a companion as feather-brained as himself he journeyed from London to Queenborough in a paper boat, with two stockfish tied to canes for oars. *The Pennyles Pilgrimage, or the Moneylesse Perambulation of John Taylor . . . how he travailed on foot from London to Edenborough in Scotland* . . . 1618, contains the account of a journey perhaps suggested by Ben Jonson's celebrated undertaking, though Taylor emphatically denies any intention of burlesque. He went as far as Aberdeen. At Leith he met Jonson, who good-naturedly gave him twenty-two shillings to drink his health in England. Other travels undertaken for a wager were a journey to Prague, where he is said to have been entertained (1620) by the queen of Bohemia, and those described respectively in *A very merry, wherry ferry voyage, or Yorke for my money*, and *A New Discovery by sea with a Wherry from London to Salisbury* (1623). At the outbreak of the civil war Taylor began to keep a public-house at Oxford, but when his friends the Royalists were obliged to surrender the city he returned to London, where he set up a similar business at the sign of "The Crown" in Phoenix Alley, Long Acre. At the time of the king's execution he changed his sign to the Mourning Crown, but the authorities objected, and he substituted his own portrait. He was buried in the churchyard of St Martin's-in-the-Fields on the 5th of December 1653.

Taylor gave himself the title of "the king's water-poet and the queen's water-man." He was no poet, though he could string rhymes together on occasion. His gifts lay in a coarse, rough and ready wit, a talent for narrative, and a considerable command of repartee, which made him a dangerous enemy. Thomas Coryate, the author of the *Crudities*, was one of his favourite butts, and he roused Taylor's special anger because he persuaded the authorities to have burnt one of Taylor's pamphlets directed against him. This was *Laugh and be Fat* (1615?), a parody of the *Odcombian Banquet*.

Sixty-three of Taylor's "works" appeared in one volume in 1630. This was reprinted by the Spenser Society in 1868–9, being followed by other tracts not included in the collection (1870–8). Some of his more amusing productions were edited (1872) by Charles Hindley as *The Works of John Taylor*. They provide some very entertaining reading, but in spite of the legend on one of his title-pages, "Lastly that (which is Rare in a Travailer) all is true," it is permissible to exercise some mental reservations in accepting his statements. Mr Hindley edited other tracts of Taylor's in his *Miscellanea Antiqua Anglicana* (1873).

TAYLOR, JOHN (1704–1766), English classical scholar, was born at Shrewsbury on the 22nd of June 1704. His father was a barber, and, by the generosity of one of his customers, the son, having received his early education at the grammar school of his native town, was sent to St John's College, Cambridge. In 1732 he was appointed librarian, in 1734 registrar of the university. Somewhat late in life he took orders, became rector of Lawford in Essex in 1751, and canon of St Paul's in 1757. He died in London on the 4th of April 1766. Taylor is best known for his editions of some of the Greek orators, chiefly valuable for the notes on Attic law, *e.g.* Lysias (1739); Demosthenes *Contra Leptinem* (1741) and *Contra Midiam* (1743, with Lycurgus *Contra Leocratem*), intended as specimens of a proposed edition, in five volumes, of the orations of Demosthenes, Aeschines, Dinarchus and Demades, of which only vols. ii. and iii. were published. Taylor also published (under the title of *Marmor Sandvicense*) a commentary on the inscription on an ancient marble brought from Greece by Lord Sandwich, containing particulars of the receipts and expenditure of the Athenian magistrates appointed to celebrate the festival of Apollo at Delos in 374 B.C. His *Elements of Civil Law* (1755) also deserves notice. It was severely attacked by Warburton in his *Divine Legation*, professedly owing to a difference of opinion in regard to the persecution of the early Christians, in reality because Taylor had spoken disparagingly of his scholarship.

TAYLOR, JOSEPH (*c.* 1586–*c.* 1653), English actor, is mentioned in the folio Shakespeare of 1623 as one of the twenty-six who took principal parts in all of these plays. There is a legend that he was trained by Shakespeare to play Hamlet, and that he succeeded Burbage in this and other parts. Certain it is that in many of Beaumont and Fletcher's plays he had a leading rôle, and he is one of the ten actors who signed the dedication of the first folio of these dramatists (1647).

TAYLOR, MICHAEL ANGELO (1757–1834), English politician, was a son of Sir Robert Taylor (1714–1788), the architect, and was educated at Corpus Christi College, Oxford, becoming a barrister at Lincoln's Inn in 1774. He entered the House of Commons as member for Poole in 1784, and, with the exception of the short period from 1802 to 1806, remained a member of parliament until 1834, although not as the representative of the same constituency. In parliament Taylor showed himself anxious to curtail the delays in the Court of Chancery, and to improve the lighting and paving of the London streets; and he was largely instrumental in bringing about the abolition of the pillory. At first a supporter of the younger Pitt, he soon veered round to the side of Fox and the Whigs, favoured parliamentary reform, and was a personal friend of the regent, afterwards George IV. He was on the committee which managed the impeachment of Warren Hastings; was made a privy councillor in 1831; and died in London on the 16th of July 1834. Taylor is chiefly known in connexion with the Metropolitan Paving Act of 1817, which is still referred to as "Michael AngeloTaylor's Act." Often called "Chicken Taylor" because of his reference to himself as a "mere chicken in the law," he is described by Sir Spencer Walpole as "a pompous barrister, with a little body and a loud voice." Taylor's father, Sir Robert, was the founder of the Taylorian Institution at Oxford.

TAYLOR, NATHANIEL WILLIAM (1786–1858), American Congregational theologian, was born in New Milford, Connecticut, on the 23rd of June 1786, grandson of Nathaniel Taylor (1722–1800), pastor at New Milford. He graduated at Yale College in 1807, studied theology under Timothy Dwight, and in 1812 became pastor of the First Church of New Haven. From 1822 until his death in New Haven on the 10th of March 1858 he was Dwight professor of didactic theology at Yale. He was the last notable representative of the New England School, in which his predecessors were the younger Edwards, John Smalley (1734–1820) and Nathaniel Emmons. In the Yale Divinity School his influence was powerful, and in 1833 one of his foremost opponents, Bennet Tyler (1783–1858), founded in East Windsor a Theological Institute to offset Taylor's teaching at Yale.

Taylorism, sometimes called the "New Haven" theology, was an attempt to defend Calvinism from Arminian attacks, and the defence itself was accused of Arminianism and Pelagianism by A. A. Hodge of Princeton and Leonard Woods of Andover. Taylor's theology was distinctively infra-lapsarian; it disagreed with Samuel Hopkins and Emmons in rejecting the theory of "divine efficiency" and in arguing that man can choose the right "even if he won't" —distinguishing like Edwards between natural ability and moral inability; it distinguished sensibility or susceptibility as something different from will or understanding, without moral qualities, to which the appeal for right choice may be made; and it made self-love (a term borrowed from Dugald Stewart, connoting the innocent love of happiness and distinct from selfishness) the particular feeling appealed to by the influences of the law and gospel.

He wrote *Practical Sermons* (1858; edited by Noah Porter); *Lectures on the Moral Government of God* (2 vols., 1859), and *Essays and Lectures upon Select Topics in Revealed Theology* (1859), all published posthumously.

TAYLOR, PHILIP MEADOWS (1808–1876), Anglo-Indian administrator and novelist, was born at Liverpool on the 25th of September 1808. At the age of fifteen he was sent out to India to become a clerk to a Bombay merchant. On his arrival the house was in financial difficulties, and he was glad to accept in 1824 a commission in the service of his highness the nizam, to which service he remained devotedly attached throughout his long career. He was speedily transferred from military duty to a civil appointment, and in this capacity he acquired a knowledge of the languages and the people of Southern India which has seldom been equalled. He studied the laws, the geology, the antiquities of the country; he was alternately judge, engineer, artist and man of letters, for on his return to England in 1840 on furlough he published the first of his Indian novels, *Confesssions of a Thug*, in which he reproduced, with singular vivacity and truth, the scenes which he had heard described by the chief actors in them. This book was followed by a series of tales, *Tippoo Sultaun* (1840), *Tara* (1863), *Ralph Darnell* (1865), *Seeta* (1872), and *A Noble Queen* (1878), all illustrating periods of Indian history and society, and giving a prominent place to the native character, for which and the native institutions and traditions he had a great regard and respect. Returning to India he acted from 1840 to 1853 as correspondent for *The Times*. He also wrote a *Student's Manual of the History of India* (1870). About 1850, Meadows Taylor was appointed by the nizam's government to administer, during a long minority, the principality of the young raja of Shorapore. He succeeded without any European assistance in raising this small territory to a high degree of prosperity, and such was his influence with the natives that on the occurrence of the mutiny in Bengal he held his ground without military support. Colonel Taylor, whose merits were now recognized and acknowledged by the British government of India—although he had never been in the service of the Company—was subsequently appointed to the deputy commissionership of the Western ceded districts, where he succeeded in establishing a new assessment of revenues at once more equitable to the cultivators and more productive to the government. By indefatigable perseverance he had raised himself from the condition of a half-educated lad, without patronage, and without even the support of the Company, to the successful government of some of the most important provinces of India, 36,000 square miles in extent and with a population of more than five millions. On his retirement from service in 1860 he was made a C.S.I. and given a pension. Taylor died at Mentone on the 13th of May 1876.

See Meadows Taylor's *The Story of My Life* (1877).

TAYLOR, ROWLAND (d. 1555), English Protestant martyr, was born at Rothbury, Northumberland; he took minor orders at Norwich in 1528 and graduated LL.B. at Cambridge in 1530 and LL.D. in 1534. Adopting reformed views he was made chaplain by Cranmer in 1540 and presented to the living of Hadleigh, Suffolk, in 1544. In Whitsun week, 1547, he preached a "notable sermon" at St Paul's Cross, and was given the third stall in Rochester cathedral. In 1549 he was placed on a commission to examine Anabaptists, and in 1551 he was appointed chancellor to Bishop Ridley, select preacher at Canterbury, and a commissioner for the reform of the canon law; in 1552 Coverdale made him archdeacon of Exeter. Apparently he advocated the cause of Lady Jane Grey, for on the 25th of July 1553, only six days after Mary's proclamation as queen, he was committed to the custody of the sheriff of Essex. He was released not long afterwards, and with the support of his parishioners offered strenuous resistance to the restoration of the Mass. He was consequently imprisoned in the King's Bench prison on the 26th of March 1554. The sturdy protestantism of Taylor and his flock, who seem to have caused various commotions, marked him out for the special enmity of Mary's government; and he was one of the first to suffer when in January 1555 parliament had once more given the clerical courts liberty of jurisdiction. He was sentenced on the 22nd, excommunicated on the 29th, degraded by Bonner on the 4th of February, and burnt on the 9th at Aldham Common near Hadleigh. His blameless character had made a great impression on his age, and he was commemorated in many popular ballads. He was regarded as the ideal of a Protestant parish priest; he was married and had nine children. The alleged descent of Jeremy Taylor from him has not been proved.

See Thomas Quinton Stow's *Memoirs of Rowland Taylor* (1833); *Dict. of Nat. Biogr.* lv. 463–4, and authorities there cited.

(A. F. P.)

TAYLOR, THOMAS (1758–1835), English writer, generally called "the Platonist," was born in London on the 15th of May 1758, and lived there till his death on the 1st of November 1835. He was sent to St Paul's school, but was soon removed to Sheerness, where he spent several years with a relative who was engaged in the dockyard. He then began to study for the dissenting ministry, but an imprudent marriage and pecuniary difficulties compelled him to abandon the idea. He became a schoolmaster, a clerk in Lubbock's banking-house, and from 1798–1806 was assistant secretary to the society for the encouragement of arts, manufactures and commerce, which post he resigned to devote himself to the study of philosophy. He had the good fortune to obtain the patronage of the duke of Norfolk and of a Mr Meredith, a retired tradesman of literary tastes, who assisted him to publish several of his works. These mainly consisted of translations of the whole or part of the writings of Aristotle, Plato, Plotinus, Proclus, Pausanias, Porphyry, Ocellus Lucanus, and the Orphic hymns. His efforts were unfavourably—almost contemptuously—received, but, in spite of defects of scholarship and lack of critical faculty, due recognition must be awarded to the indomitable industry with which he overcame early difficulties. He figures as the "modern Pletho" in Isaac Disraeli's *Curiosities of Literature* and in his novel *Vaurien*, and as "England's gentile priest" in Mathias's *Pursuits of Literature*.

TAYLOR, TOM (1817–1880), English dramatist and editor of *Punch*, was born at Bishop Wearmouth, near Sunderland, on the 19th of October 1817. After attending school there, and studying for two sessions at Glasgow University, he in 1837 entered Trinity College, Cambridge, of which he became a fellow. Subsequently he held for two years the professorship of English literature at University College, London. He was called to the bar (Middle Temple) in November 1846, and went on the northern circuit until, in 1850, he became assistant secretary of the Board of Health. On the reconstruction of the Board in 1854 he was made secretary, and on its abolition his services were transferred to a department of the Home Office, retiring on a pension in 1876. In his very early years Tom Taylor had shown a predilection for the drama, and had been in the habit of performing dramatic pieces with a number of children in a loft over a brewer's stable. Four burlesques of his were produced at the Lyceum in 1844. He made his first hit with *To Parents and Guardians*, brought out at the Lyceum in 1845. He also wrote some burlesques in conjunction with Albert Smith and Charles Kenny, and collaborated with Charles Reade in *Masks and Faces* (1852). Before the close of his life his dramatic pieces numbered over 100, amongst the best known of which are *Our American Cousin* (1858), produced by Laura Keene in New York, in which Sothern created the part of Lord Dundreary; *Still Waters Run Deep* (1855); *Victims* (1857); the *Contested Election* (1859); the *Overland Route* (1860); the *Ticket of Leave Man* (1863); *Anne Boleyn* (1875); and *Joan of Arc* (1871). He was perhaps the most popular dramatist of his time; but, if his chief concern was the construction of a popular acting play, the characters in his dramas are clearly and consistently drawn, and the dialogue is natural, nervous and pointed. In his blank verse historical dramas, *Anne Boleyn* and *Joan of Arc*, he was not so successful.

Taylor had begun his career as a journalist when he first came to London. He very soon became connected with the *Morning Chronicle* and the *Daily News*, for which he wrote leaders. He was on the staff of *Punch* until 1874, when he succeeded Shirley Brooks as editor. He occasionally appeared with success in amateur theatricals, more especially in the character of Adam in *As You Like It* and of Jasper in *A Sheep in Wolf's Clothing*. He had some talent for painting, and for many years was art critic to *The Times* and the *Graphic*. He died at Lavender Sweep, Wandsworth, on the 12th of July 1880.

Apart from the drama, Tom Taylor's chief contributions to literature are his biographies of painters, viz., *Autobiography of B. R. Haydon* (1853); *Autobiography and Correspondence of C. R. Leslie, R.A.* (1860); and *Life and Times of Sir Joshua Reynolds* (1865), which had been left in a very incomplete state by Leslie. His *Historical Dramas* appeared in one volume in 1877. He also edited, with a memorial preface, *Pen Sketches from a Vanished Hand, selected from Papers of the late Mortimer Collins.*

TAYLOR, WILLIAM (1765–1836), English man of letters, son of a Norwich manufacturer, was born in that city on the 7th of November 1765. He belonged to the Unitarian community, and went to a school kept at Palgrave, Suffolk, by Rochemont Barbauld, husband of Anna Letitia Barbauld, where Frank Sayers (1763–1817) was among his schoolmates. He travelled on the Continent for some years to perfect himself in foreign languages. William Taylor and his father were both in sympathy with the French Revolution, and belonged to a "revolution society" at Norwich. In 1791 the disturbed condition of affairs induced the elder Taylor to wind up his business, and from this time William devoted himself to letters. He was an enthusiast for German poetry, and did great service to English literature by translations of Bürger's *Lenore* (1790, printed 1796), of Lessing's *Nathan the Wise* (1790, printed 1805), of Goethe's *Iphigenia in Tauris* (1790, printed 1793), and of four of Wieland's *Dialogues of the Gods* (1795). He was a prolific writer of review articles, in which his knowledge of foreign literature served as a useful standard of criticism. Much of this material was made use of in his most important work, his *Historic Survey of German Poetry* (3 vols., 1828–30). He also edited the works of his friend Sayers with a memoir (1823). He died at Norwich on the 5th of March 1836.

See a *Memoir of the Life and Writings of the late W. Taylor of Norwich*, by John Warden Robberds (2 vols., 1843); Georg Herzfeld, *William Taylor von Norwich* (1897). Taylor is well known to readers of George Borrow by the portrait of him as the "elder individual" in the 23rd chapter of *Lavengro.*

TAYLOR, ZACHARY (1784–1850), twelfth president of the United States, was born in Orange county, Virginia, on the 24th of September 1784. During the following year his father, Colonel Richard Taylor, a veteran of the War of Independence, migrated to Kentucky, settling near Louisville, and thereafter played an important part in the wars and politics of his adopted state. The boyhood and youth of Zachary Taylor were thus passed in the midst of the stirring frontier scenes of early Kentucky, and from this experience he acquired the hardihood and resoluteness that characterized his later life, although he inevitably lacked the advantages of a thorough education. In May 1808 Taylor received a commission as first lieutenant in the 7th United States Infantry, and for the next few years was employed in routine duties. Early in 1812 he was made captain, and during the ensuing hostilities with Great Britain distinguished himself by his gallant defence against the Indians of Fort Harrison, a stockade in central Indiana. For this he was breveted major, and in May 1814 received a regular major's commission, but being reduced at the conclusion of the war to the rank of captain, temporarily left the service. In May 1816 he was reinstated as major, and in 1819 was promoted to be a lieutenant-colonel; and in the routine discharge of his duties he was stationed at various posts on the western frontier. In 1832, as colonel, he took part in the Black Hawk War, and was the officer to whom Black Hawk surrendered; later he occasionally acted as Indian agent along the upper Mississippi.

In 1836 Taylor was ordered from Wisconsin to take command against the Seminoles in Florida. On the 25th of December 1837, after a difficult campaign, he inflicted a severe defeat upon the Indians at the battle of Okeechobee, and for this was breveted brigadier-general. Then followed four years of harassing service in the Florida Everglades, whence he passed to the command of the First Department of the army, with headquarters at Fort Jesup, Louisiana.

While at New Orleans in 1845, Taylor received orders from President Polk to march his troops into Texas, as soon as that state should accept the terms of annexation proposed by the Joint Resolution of Congress of March 2, 1845. Later in June Polk, who assumed that the Rio Grande rather than the Nueces was the south-western boundary of Texas, ordered him to take up a position at the mouth of the Sabine, or at some other point best suited for an advance to the former river. By the middle of August Taylor had selected a position at Corpus Christi, on the west bank of the Nueces and within the disputed territory, and here he remained until the following spring. Upon the definite refusal of the Mexican government under Paredes to resume with the United States the diplomatic relations broken off by the annexation of Texas, Taylor was ordered to advance to the Rio Grande for the purpose of anticipating any hostile incursion from Mexico. He himself favoured such a movement if the United States was to maintain its claim as regards the boundary. In obedience to his instructions he left Corpus Christi on the 12th of March 1846, fortified Point Isabel as a base of supplies, and took up his position on the disputed river, opposite the Mexican town of Matamoras. Here he began to construct Fort Texas, afterwards called Fort Brown, upon the present site of Brownsville. The commander of the Mexican Army of the North, Ampudia, immediately summoned him to retire behind the Nueces under the threat of interpreting his advance as an invasion of Mexican territory. Taylor not only disregarded this summons, but within the following week proceeded to blockade the Rio Grande. Hostilities were then unavoidable, and the first passage at arms occurred on the 24th of April 1846, when a large force of Mexicans on the east bank of the Rio Grande ambushed and captured a small party of American dragoons under Captain Seth B. Thornton (1814–1847). The news of this event led President Polk, on the 11th of May, to recommend a formal declaration of war on the ground that it existed "by the act of Mexico herself," for that power "has passed the boundary of the United States, has invaded our territory and shed American blood upon American soil." This statement was incorporated in the bill declaring war, and although severely criticized during the Senate debate, passed both houses of Congress by overwhelming majorities.

Meanwhile Taylor had strengthened his base of supplies at Point Isabel, where he was reinforced by militia from Texas and Louisiana, and during the return march from this post was fiercely attacked at Palo Alto (about 8 m. N.E. of Brownsville, Texas) on May 8th, by the Mexicans under Arista. The latter was easily driven from the field, but on the following day threatened Taylor's advance in a much stronger position, Resaca de la Palma (about 4 m. N. of Brownsville). A brilliant charge by the dragoons under Captain May decided this contest, which Taylor followed up by a pursuit of the Mexican general to the Rio Grande. After relieving Fort Brown, which had been besieged since the 3rd of May, Taylor himself crossed the river, and on the 18th of May occupied Matamoras, from which Arista had already retreated to Monterrey.

As it was the intention of the administration to wage war for the purpose merely of bringing Mexico to negotiate, Taylor did not immediately advance southward from the Rio Grande. When, however, Mexico persisted in her refusal to treat, Polk decided to conquer her northern provinces. Taylor formed a new base of operations at Camargo, farther up the river, and from this point, in August began an advance towards Monterrey, the capital of Nuevo Leon. After hard fighting he occupied this city in the latter part of September (see MONTERREY). The truce with which he followed up this success was unacceptable to the administration, and upon receiving notice to resume hostilities, he occupied Saltillo, the capital of Coahuila, and Victoria, the capital of Tamaulipas, thus completing the conquest of the north-eastern states of Mexico. By this time Taylor had been reinforced by some 3000 troops which had marched under Gen. John E. Wool from San Antonio directly towards Chihuahua, but which had been deflected at Monclova to join his "army of occupation." During the war he was breveted major-general (May 1846), and Congress thrice passed votes of thanks and ordered the presentation of commemorative gold medals. President Polk distrusted Taylor because of his supposed Whig views, and now began to express his dissatisfaction with the general's failure to take full advantage of his victories and his hesitancy to suggest a plan for the future conduct of the war. Taylor was unwilling to lead his own army farther into the desert interior of Mexico and remained non-committal upon the projected attempt from Vera Cruz. When Polk finally determined upon the latter campaign, he selected Gen. Winfield Scott, although the latter was personally unacceptable to himself, as its leader, and despite Taylor's vigorous protests detached most of his experienced troops to join Scott's command. Meanwhile through the connivance of the American authorities, Santa Anna returned from his Cuban exile, and, as the newly elected Mexican president, disregarding his pledges to aid Polk in bringing about a satisfactory peace, prepared to wage a more effective war against the American invaders. Learning of the weakened condition of Taylor's force he made a sudden advance to the northward, with some 20,000 troops, and on the 22nd of February 1847 encountered Taylor with one-fourth that number at Buena Vista, a few miles beyond Saltillo. The all-day battle in the narrow mountain pass was the most stubbornly contested of the whole war, and the brilliant victory of Taylor over such odds made "Old Rough and Ready," as he was called by his troops, the hero of the hour. With this encounter the serious work of his "army of occupation" ended, although he was later joined by Gen. Alexander W. Doniphan's troops, who had marched from New Mexico *via* Chihuahua. Taylor's brilliant victory, won when he was so greatly handicapped by Polk, emphasized the popular discontent which that president's policy had already aroused, and suggested him to the political leaders as a presidential possibility. The general, however, had passed his mature years wholly in military service and had never voted, much less strongly allied himself, with any political party. Nevertheless when Taylor meetings became the fashion and newspapers began to advocate his nomination, party lines threatened to disappear despite the frantic efforts of the old-time chiefs of the two leading organizations to stem the tide against the popular favourite. The Democratic party with its more efficient machinery prevented a stampede of its rank and file, but the Whigs were less successful. Within a month after his victory over Santa Anna a Whig convention in Iowa nominated him for the presidency, and public meetings in Kentucky, Ohio, Virginia, Pennsylvania and elsewhere quickly took similar action, in many cases without regard to party lines. Taylor first adopted a course of discouraging these suggestions and emphasized his non-partisan attitude, but later gave way to the pressure, and issued a statement that proved satisfactory to the majority of the Whig politicians. Yet it required four ballots in the national convention to overcome the reluctance of Webster's, Clay's and Scott's followers and secure the party nomination. The disaffection of these leaders was more than counterbalanced, however, by the split of the New York Democrats over the slavery question, which assured Taylor of the vote of that state. His residence in Louisiana, his ownership of a large plantation with its slaves, and his family connexion with Jefferson Davis (who had married his daughter), rendered him more acceptable to many of the Southern Democrats than their party candidate, Lewis Cass, an advocate of "squatter sovereignty" and the representative of the democracy of the free North-west. As a result Taylor carried eight slave states while his opponent secured seven, but in the free states the conditions were exactly reversed. He received a majority of electoral votes on each side of the Mason and Dixon line and was confirmed in his preconceived opinion that he was to be the president of the whole people. Both parties had attempted to avoid the burning slavery issue,—the Whigs by adopting no platform whatever and the Democrats by trusting to the well-known views of their candidate, but the political leaders in Congress could not escape the many definite questions presented by the possession of the territory newly acquired from Mexico. The Wilmot Proviso and the bill to organize the territory of Oregon had already aroused both sections and had given occasion for Webster and Calhoun to state their respective views upon the constitutional questions involved. The three weeks' contest over the election of a speaker in the House of Representatives, in December 1849, emphasized the sectional passions already engendered. Under the circumstances the first message from President Taylor was awaited with great interest. While advising Congress to "abstain from the introduction of those exciting topics of sectional character which have hitherto produced painful apprehensions in the public mind," he favoured the admission of California as a free state, and counselled the legislators to await the action of the people of New Mexico and Utah upon the slavery question. As he had already encouraged California to form the state government it desired, and later took a strong position against the efforts of Texas to possess itself of part of New Mexico, it was apparent that he was less inclined to favour the radical pro-slavery programme than his previous career had seemed to promise. This was still further emphasized by his marked friendship for William H. Seward and his contemptuous reference to the territorial portion of Clay's compromise measures as the "Omnibus Bill." This situation militated greatly against that leader's cherished policy, and led him to a bitter criticism of the president on the floor of the Senate. Such was the situation when the president, early in July 1850, was stricken by the disease to which he succumbed on the 9th. His remains were temporarily interred at Washington, but afterwards removed to the family cemetery near Louisville.

The only son that survived him, RICHARD TAYLOR (1826–1879), popularly known as "General Dick," graduated at Yale in 1845, entered the Confederate army at the beginning of the Civil War, was commanding officer in Louisiana, and under Kirby Smith helped to administer the western half of the Confederacy, after the fall of Vicksburg. He won the victory of Sabine Cross Roads over the Union expedition under Gen. N. P. Banks on the 8th of April 1864. He finally surrendered to Gen. E. R. S. Canby on the 4th of May 1865. He wrote *Destruction and Reconstruction* (1879).

H. Montgomery's *Life* (Auburn, 1850) and John Frost's *Life* (New York and Philadelphia, 1847) are almost wholly devoted to President Taylor's military career, and are excessively laudatory in character. A better biography is that (New York, 1892) by Maj.-Gen. O. O. Howard, in the "Great Commanders" series. There is much material about Taylor in the general histories of M'Master, Von Holst, and Rhodes. (I. J. C.)

TAYLOR, a town in Williamson county, Texas, U.S.A., about 35 m. N.E. of Austin. Pop. (1890) 2584; (1900) 4211 (1260 negroes); (1910) 5314. It is served by the International & Great Northern and the Missouri, Kansas & Texas railways. It is in a region especially devoted to the growing of cotton and grain and to poultry raising, and an annual county fair is held here. In the city are machine and car shops of the International & Great Northern railway, and cotton-compresses, and there are manufactures of cotton-seed oil, &c. Taylor, named in honour of Gen. Zachary Taylor, was founded in 1876, and was incorporated in 1882.

TAYPORT, a police burgh of Fifeshire, Scotland. Pop. (1901) 3325. It is situated on the Firth of Tay, here about 1 m. wide, opposite to Broughty Ferry, with which there is communication by means of a ferry, 5½ m. N. of Leuchars Junction by the North British railway. Its older alternative name of Ferry Port on Craig has reference both to its uses and its site. Its industries include manufactures of linen and jute, spinning mills, engineering works, timber-yard and salmon fishery. In other respects it is a residential quarter for Dundee. A mile S.W. is the estate of Scotscraig, which belonged to Archbishop Sharp (1613–1679), of whose mansion there are still some traces. Two miles and a half W. by S. is the police burgh of NEWPORT (pop. 2869), with stations at Easter and Wester Newport, on the North British Railway Company's loop line from Leuchars Junction to Wormit. It lies on the Firth of Tay opposite to Dundee, with which there is communication by means of a ferry, as well as by rail via the Tay Bridge. Even to a greater extent than has Tayport, it has practically become a suburb of Dundee. Its small harbour was designed by Telford. Two and a quarter miles S.W. of Wormit, the nearest railway station, close to the southern terminus of the Tay Bridge, is the village of BALMERINO (Gaelic, "Town on the seashore"). Its once considerable shipping trade has declined, but some fishery is still carried on. In 1227 Ermengarde, widow of William the Lion, and her son Alexander II. founded a Cistercian Abbey here, but in 1604 the Abbey estates were converted into a temporal lordship in favour of James Elphinstone, created Lord Balmerino.

TAYUG, a town of the province of Pangasinan, Luzon, Philippine Islands, near the Agno river, 33 m. E. of Lingayen, the capital. Pop. (1903) 10,400. The river furnishes water for irrigating the low fields in the vicinity. The town's inhabitants are farmers, and rice is the principal crop. Pangasinan and Ilocano are the languages spoken.

TAZZA (Ital., cf. Fr. *tasse*, Ger. *Tasse*, cup; all from Persian *tas*, goblet), a word generally adopted by archaeologists and connoisseurs for a type of drinking vessel. It is a shallow saucer-like dish either mounted on a stem and foot or on a foot alone.

TCHERNAIEV, MIKHAIL GREGORJOVICH (1828–1898), Russian general, a member of a noble family, was born on the 24th of October 1828. Educated at the Nicholas Staff College, he entered the army in 1847, and distinguished himself in the Crimean war and in the Caucasus. After serving as divisional chief of the staff in Poland, he went to Orenburg in 1858 as assistant to the commander of the line of the Syr-Darya, and the following year commanded an expedition to support the Kirghiz tribes on the borders of the Sea of Aral against the Khivans. He did duty on the staff of the army of the Caucasus for a time, and returned to Orenburg as chief of the staff. In 1864, having reached the rank of major-general, he made his famous march with 1000 men across the steppes of Turkestan to Chimkent in Khokand, to meet another Russian column from Semipalatinsk, in Siberia, in conjunction with which he successfully stormed Chimkent, and then unsuccessfully attacked Tashkent, 80 miles farther south. Wintering at Chimkent, he captured Tashkent the following year. This was contrary to his instructions, and although he was received in St Petersburg with enthusiasm, and presented with a sword of honour by the emperor, he was not again employed in the military service, and retired from it in July 1874. He bought, and edited with great success, the *Russkiy Mir* in Slavonic interests, devoting himself to the Panslavic idea. In the summer of 1876 he was appointed commander-in-chief of the Servian army, but on entering Turkey was driven back by Osman Pasha, who followed him into Servia, defeating him at Zayechar and Yavor in July, and the campaign in Servia proved disastrous. He rashly proclaimed Milan king of Servia in September, and in October Aleksinats and Deligrad were in the hands of the Turks, and the road open to Belgrade. An armistice was concluded, and Tchernaiev resigned his command. In 1877 he visited Austria in connexion with his propaganda, but was expelled, and lived for a time in France. In 1879 he organized a Bulgarian rising, but was arrested at Adrianople and sent back to Russia. He succeeded Kaufmann (*q.v.*) as governor of Turkestan in 1882, but his aggressive policy led to his recall two years later, when he was appointed a member of the council of war at St Petersburg. In 1886 his opposition to the Central Asian Military railway caused him to lose his seat in the council. He died on the 16th of August 1898, at his country seat in the province of Mogilev.

TCHIHATCHEFF, PIERRE ALEXANDROWITSCH DE (1812–1890), Russian naturalist and geologist, was born at Gatchina, near St Petersburg, in 1812. He entered the diplomatic service and was (1842–44) attached to the embassy at Constantinople; whence he visited Asia Minor, Syria and Egypt. In 1844, he was charged with a scientific mission to the Altai mountains. He died at Florence on the 13th of October 1890 (N.S.).

His publications include: *Voyage scientifique dans l'Altai oriental et les parties adjacentes de la frontière de Chine* (with atlas, 1845); *Asie Mineure; description physique, statistique et archéologique de cette contrée* (4 vols. with 3 atlases, 1853–69); *Le Bosphore et Constantinople* (1864, another ed. 1877); *Considérations géologiques sur les Îles Océaniques* (1878); and *Espagne, Algérie et Tunisie* (1880).

TEA (Chinese *cha*, Amoy dialect *tê*), the name given to the leaves of the tea bush (see below) prepared by decoction as a beverage The term is by analogy also used for an infusion or decoction of other leaves, *e g.* camomile tea; and similarly for the afternoon meal at which tea is served.

Historical.—The early history of tea as a beverage is mainly traditional. The lack of accurate knowledge regarding the past of the Chinese Empire may possibly some day be supplied, as European scholars become more able to explore the unstudied stores in the great Chinese libraries, or as Chinese students ransack the records of their country for the facts of earlier periods. It may then be learnt who made the first cup of tea, who planted the earliest bushes, and how the primitive methods of manufacture were evolved. In the meantime knowledge on the subject is mingled with much that is obviously mythical and with gleanings from the casual references of travellers and authors.

According to Chinese legend, the virtues of tea were discovered by the Emperor Chinnung, 2737 B.C., to whom all agricultural and medicinal knowledge is traced. It is doubtfully referred to in the book of ancient poems edited by Confucius, all of which are previous in date to 550 B.C. A tradition exists in China that a knowledge of tea travelled eastward to and in China, having been introduced 543 A.D. by Bodhidharma, an ascetic who came from India on a missionary expedition, but that legend is also mixed with supernatural details. But it is quite certain, from the historical narrative of Lo Yu, who lived in the Tang dynasty (618–906 A.D.), that tea was already used as a beverage in the 6th century, and that during the 8th century its use had become so common that a tax was levied on its consumption in the 14th year of Tih Tsung (793). The use of tea in China in the middle of the 9th century is known from Arab sources (Reinaud, *Relation des Voyages*, 1845, p. 40). From China a knowledge of tea was carried into Japan, and there the cultivation was established during the 9th century. Seed was brought from China by the priest Miyoye, and planted first in the south island, Kiushiu, whence the cultivation spread northwards till it reached the high limit of 39° N.

It is somewhat curious that although many of the products of China were known and used in Europe at much earlier times, no reference to tea has yet been traced in European literature prior to 1588. No mention of it is made by Marco Polo, and no knowledge of the substance appears to have reached Europe till after the establishment of intercourse between Portugal and China in 1517. The Portuguese, however, did little towards the introduction of it into Europe, and it was not till the Dutch established themselves at Bantam early in the 17th century that these adventurers learned from the Chinese the habit of tea drinking and brought it into Europe.

The earliest mention of tea by an Englishman is probably that contained in a letter from Mr Wickham, an agent of the East India Company, written from Firando in Japan, on the 27th June 1615, to Mr Eaton, another officer of the company, resident at Macao, and asking for "a pot of the best sort of *chaw*." How the commission was executed does not appear, but in Mr Eaton's subsequent accounts of expenditure occurs this item—"three silver porringers to drink chaw in."

It was not till the middle of the century that the English began to use tea, and they also received their supplies from Java till in 1686 they were driven out of the island by the Dutch. At first the price of tea in England ranged from £6 to £10 per lb. In the *Mercurius Politicus*, No. 435, of September 1658, the following advertisement occurs:— "That excellent and by all Physitians approved China Drink called by the Chineans *Tcha*, by other nations *Tay*, *alias Tee*, is sold at the Sultaness Head, a cophee-house in Sweetings Rents, by the Royal Exchange, London." Thomas Garway, the first English tea dealer, and founder of the well-known coffee-house, "Garraway's," in a curious broadsheet, *An Exact Description of the Growth, Quality and Virtues of the Leaf Tea*, issued in 1659 or 1660, writes, "in respect of its scarceness and dearness, it hath been only used as a regalia in high treatments and entertainments, and presents made thereof to princes and grandees." In that year he purchased a quantity of the rare and much-prized commodity, and offered it to the public, in the leaf, at fixed prices varying from 15s. to 50s. the lb, according to quality, and also in the infusion, "made according to the directions of the most knowing merchants and travellers into those eastern countries." In 1660 an Act of the first parliament of the Restoration imposed a tax on "every gallon of chocolate, sherbet and tea, made and sold, to be paid by the maker thereof, eightpence" (12 Car. II. c. 23).

Pepys's often-quoted mention of the fact that on the 25th September 1660, "I did send for a cup of tee, a China drink, of which I never had drunk before," proves the novelty of tea in England at that date. In 1664 we find that the East India Company presented the king with 2 lb and 2 oz. of "thea," which cost 40s. per lb, and two years afterwards with another parcel containing 22¾ lb, for which the directors paid 50s per lb. Both parcels appear to have been purchased on the Continent. Not until 1677 is the Company recorded to have taken any steps for the importation of tea. The order then given to their agents was for "teas of the best kind to the amount of 100 dollars." But their instructions were considerably exceeded, for the quantity imported in 1678 was 4713 lb, a quantity which seems to have glutted the market for several years. The annals of the Company record that, in February 1684, the directors wrote thus to Madras:— "In regard thea is grown to be a commodity here, and we have occasion to make presents therein to our great friends at court, we would have you to send us yearly five or six canisters of the very best and freshest thea." Until the Revolution no duty was laid on tea other than that levied on the infusion as sold in the coffee-houses. By 1 William and Mary, c. 6, a duty of 5s. per lb and 5 per cent. on the value was imposed. For several years the quantities imported were very small, and consisted exclusively of the finer sorts. The first direct purchase in China was made at Amoy, the teas previously obtained by the Company's factors having been purchased in Madras and Surat, whither it was brought by Chinese junks after the expulsion of the British from Java. During the closing years of the century the amount brought over seems to have been, on the average, about 20,000 lb a year. The instructions of 1700 directed the supercargoes to send home 300 tubs of the finer green teas and 80 tubs of bohea. In 1703 orders were given for "75,000 lb Singlo (green), 10,000 lb imperial, and 20,000 lb bohea." The average price of tea at this period was 16s. per lb.

As the 18th century progressed the use of tea in England rapidly increased, and by the close of the century the rate of consumption exceeded an average of 2 lb per person per annum, a rate in excess of that of to-day of all people except those of Mongol and Anglo-Saxon origin. The business being a monopoly of the East India Company, and a very profitable one, the company at an early stage of its development endeavoured to ascertain whether tea could not be grown within its own dominions. Difficulties with China doubtless showed the advisability of having an independent source of supply. In 1788 Sir Joseph Banks, at the request of the directors, drew up a memoir on the cultivation of economic plants in Bengal, in which he gave special prominence to tea, pointing out the regions most favourable for its cultivation. About the year 1820 Mr David Scott, the first commissioner of Assam, sent to Calcutta from Kuch Behar and Rangpur—the very districts indicated by Sir Joseph Banks as favourable for tea-growing—certain leaves, with a statement that they were said to belong to the wild tea-plant. The leaves were submitted to Dr Wallich, government botanist at Calcutta, who pronounced them to belong to a species of *Camellia*, and no result followed on Mr Scott's communication. These very leaves ultimately came into the herbarium of the Linnean Society of London, and have authoritatively been pronounced to belong to the indigenous Assam tea-plant. Dr Wallich's attribution of this and other specimens subsequently sent in to the genus *Camellia*, although scientifically defensible, unfortunately diverted attention from the significance of the discovery. It was not till 1834 that, overcome by the insistence of Captain Francis Jenkins, who maintained and proved that, called by the name *Camellia* or not, the leaves belonged to a tea-plant, Dr Wallich admitted "the fact of the genuine tea-plant being a native of our territories in Upper Assam as incontrovertibly proved." In the meantime a committee had been formed by Lord William Bentinck, the governor-general, for the introduction of tea culture into India, and an official had already been sent to the tea districts of China to procure seed and skilled Chinese workmen to conduct operations in the Himalayan regions. The discovery and reports of Captain Jenkins led to the investigation of the capacities of Assam as a tea-growing country by Lord William Bentinck's committee. Evidence of the abundant existence of the indigenous tea-tree was obtained; and the directors of the East India Company resolved to institute an experimental establishment in Assam for cultivating and manufacturing tea, leaving the industry to be developed by private enterprise should its practicability be demonstrated.

In 1834 the monopoly of the East India Company was abolished and an era of rapid progress in the new industry began. In 1836 there was sent to London 1 lb of tea made from indigenous leaves; in 1837 5 lb of Assam tea were sent; in 1838 the quantity sent was 12 small boxes, and 95 boxes reached London in 1839. In 1840 there were grown, and offered at public auction in Calcutta early the following year, 35 packages, chiefly green teas, stated to have been manufactured by a chief of the Singpho tribe aided by the government establishment. In the same auction catalogue were included 95 packages, "the produce of the Government Tea Plantation in Assam," many of which bore the Chubwa mark, one well known to this day. This auction is most interesting as being the first of British-grown tea, and it included about 6000 lb. It is of interest also for the reference to the Singpho tribe, who are even now in small numbers in the same district, where they still produce in a primitive manner tea plucked from the indigenous trees growing in their jungles.

In January 1840 the Assam Company was formed to take over the early tea garden of the East India Company, and this, the premier company, is still in existence, having produced up to 1907 no less than 117,000,000 lb of tea and paid in dividends £1,360,000 or 730 per cent. on capital. It is no longer the first company in extent of yield, as the Consolidated Tea and Lands Company produced in 1907 about 15,000,000 lb of tea, besides other products. The introduction of Chinese seed and Chinese methods was a mistake, and there seems little reason to doubt that, in clearing jungle for tea planting, fine indigenous tea was frequently destroyed unwittingly in order to plant the inferior China variety. The period of unlearning the Chinese methods, and replacing the Chinese plants, had to be lived through. Vicissitudes of over-production and inflation came to interfere with an even course of success, but the industry developed and has increased enormously. From its point of origin in Assam, it has gradually spread to other districts with varying commercial success. The aggregate total of capital of the tea-producing companies in India and Ceylon now amounts to about £25,000,000.

The Dutch were rather earlier than the English in attempting to establish tea growing in their eastern possessions. A beginning was made in Java in 1826, but probably because of the even more marked influence of Chinese methods and Chinese plant, the progress was slow and the results indifferent. Of late years, however, by the introduction of fine Assam seed and the adoption of methods similar to those in use in India, a marked improvement has taken place, and there seems little reason to doubt that, with the very rich soil and abundant cheap labour that the island of Java possesses, the relative progress there may be greater in future than in any other producing land.

Somewhere about 1860 the practical commercial growing of tea was introduced into the island of Formosa. The methods of cultivation and manufacture followed there differ in many ways from those of the other large producing countries, but the industry has been fairly successful throughout its history.

Attempts were repeatedly made to introduce tea culture in Ceylon, under both Dutch and British authority. No permanent success was attained till about 1876, when the disastrous effects of the coffee-leaf disease forced planters to give serious attention to tea. Since that period the tea industry has developed with marvellous rapidity, and now takes first rank in the commerce of the island.

Several plantations have been successfully put out both by the Russian government and private enterprise in the Caucasus, but it is doubtful whether they could exist long but for the high rate of duty on tea entering Russia from foreign countries. Natal has now about 5000 acres under tea giving a fairly large yield, but of quality not highly esteemed outside of South Africa, where it benefits to the extent of 4d. per pound of protection in the tariff. A small plantation exists in South Carolina under circumstances not conducive to financial success on a large scale of production. Attempts at tea growing have been made in the West Indies, Brazil, Australia, Nyassaland, Mauritius, the Straits Settlements, Johore, Fiji and at San Miguel in the Azores without marked success. In addition to favourable conditions of soil and climate, abundant cheap labour is an absolute necessity if satisfactory commercial results are to be obtained.

Botany.—The tea bush or tree is a member of the natural order Ternstroemiaceae and is closely allied to the well-known ornamental shrub the camellia. As cultivated in China it is an evergreen shrub growing to a height of from 3 to 5 ft. The stem is bushy, with numerous and very leafy branches; the leaves are alternate, leathery in texture, elliptical, obtusely serrated, strongly veined and placed on short channelled footstalks. The flowers are white, axillary and slightly fragrant,—often two or three together on separate pedicels. The calyx is small, smooth and divided into five obtuse sepals. The corolla has from five to nine petals, cohering at the base. The stamens are short, numerous and inserted at the base of the corolla; the anthers are large and yellow, and the long style ends in three branches. The fruit is a woody capsule of three cells, each containing one large nearly spherical seed, which consists mainly of two large hemispherical cotyledons.

As is commonly the case with plants which have been long under cultivation, there has been some doubt as to specific distinctions among the varieties of tea. The plant was originally described by Linnaeus as one species, *Thea sinensis*. Later Linnaeus established two species, viz. *Thea Bohea* and *Thea viridis*, and it was erroneously assumed that the former was the source of black teas, while *Thea viridis* was held to yield the green varieties. In 1843, however, Mr Robert Fortune found that, although the two varieties of the plant existed in different parts of China, black and green tea were produced from the leaves of the same plant by varying the manufacturing processes.

Sir George Watt (*Journal of the Royal Horticultural Society*, vol. xxxii.) describes with ample illustrations the recognized varieties, placing all of them under *Camellia Thea*, with the following subdivision:—

A. Variety Viridis:—races
1. Assam Indigenous.
2. Lushai.
3. Naga Hills.
4. Manipur.
5. Burma and Shan.
6. Yunnan and Chinese.

B. ,, Bohea.
C. ,, Stricta.
D. ,, Lasiocalyx.

Of the foregoing, the teas of commerce are derived almost entirely from the varieties Viridis and Bohea. The Assam Indigenous, in its two sub-races of Singlo and Bazalona, and the Manipur, originally found wild in the jungles of the native state of that name, have, with various intermixtures and crossings, been used to cover the greatest areas of all the more modern planting in India, Ceylon and Java. The great size of leaf when fully developed (4 to 9 ins. in length and 2 to $3\frac{1}{2}$ in breadth) has made them in demand because of the heavy yields. From the variety Bohea, or from hybrids of descent from it, came the China teas of former days and the earlier plantings in India grown from imported China stock. The

FIG. 1.—Bohea variety.

leaves of this variety are generally, roughly speaking, about half the size of those of the Assam Indigenous and Manipur sorts. The bush is in every way smaller than the Assam types. The latter is a tree attaining in its natural conditions, or where allowed to grow unpruned in a seed garden, a height of from 30 to 40 ft. and prospering in the midst of dense moist jungle and in shady sheltered situations.

FIG. 2.—Bohea Tea-leaf, full size.

The Bohea variety is hardy, and capable of thriving under many different conditions of climate and situation, while the indigenous plant is tender and difficult of cultivation, requiring for its success a close, hot, moist and equable climate. In minute structure it presents highly characteristic appearances.

The under side of the young leaf is densely covered with fine one-celled thick-walled hairs, about 1 mm. in length and ·015 mm. in thickness. These hairs entirely disappear with increasing age. The structure of the epidermis of the under side of the leaf, with its contorted cells, is represented (×160) in fig. 3.

A further characteristic feature of the cellular structure of the tea-leaf is the abundance, especially in grown leaves, of large, branching, thick-walled, smooth cells (idioblasts), which, although they occur in other leaves, are not found in such as are likely to be confounded with or substituted for tea. The minute structure of the leaf in section is illustrated in fig. 4.

Constant controversy has existed as to what is the actual original home of the tea-plant, and probably no one has given to the subject more careful study than Professor Andreas Krassnow, of Kharkoff University. By order of the Russian government, he visited each of the great tea-growing countries, and the results of his observations were published in a book entitled *On the Tea-producing Districts of Asia.* He holds the opinion that the tea-plant is indigenous, not to Assam only, but to the whole monsoon region of eastern Asia, where he found it growing wild as far north as the islands of southern Japan. He considers that the tea-plant had, from the remotest times, two distinct varieties, the Assam and Chinese, as he thinks that the period of known cultivation has been too short to produce the differences that exist between them.

Chemistry.—What may be termed the chemistry of production, viz., that relating to soils, manures, manufacturing processes, &c., has of recent years received great attention from the scientific

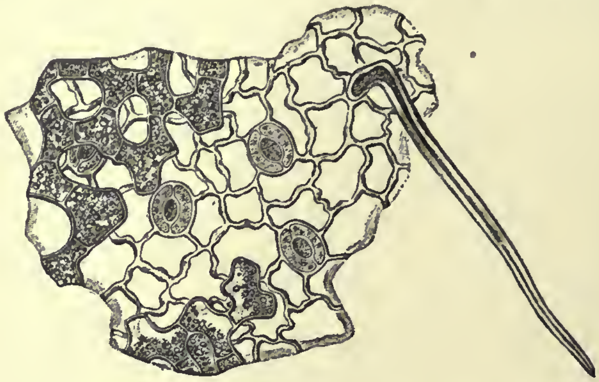

FIG. 3.—Epidermis of Tea-leaf (under side). ×160.

experts appointed in India and Ceylon to assist and guide the tea planters. The chemistry of the completed teas of commerce does not appear to have been subjected to adequate scientific study. There cannot be said to be any standard or recognized analysis. Many such have been made, and they may be found in chemical text-books of high authority, but they are defective because of the lack of commercial knowledge in association with the chemical skill. More attention seems to have been given to the matter in the United States of America and in Germany and Russia than in England, but the infinite variety of samples known to the commercial expert, and the impossibility of standardizing those in such a manner as to make readily recognizable what the chemist has treated, renders most of the recorded analyses of uncertain value. There seems to be no relationship between the commercial value and the analysis, the arbitrary personal methods of the expert tea-taster being controlled by factors that chemistry does not appear to deal with. One reason may be that analyses are generally made of tea liquors produced by distilled water, which is the very worst possible from the point of view of the commercial expert or in domestic usage.

FIG. 4.—Section through Tea-leaf.

The principal chemical constituents of tea of practical interest are: caffeine, tannin and essential oil, on which depend respectively the physiological effects, the strength and the flavour. The commercial value appears to depend on the essential oil and aroma, not on the amount of caffeine, tannin or extract.

The following is suggested as a typical analysis of an average sample of black tea:—

	Per cent.
Albuminous matters	24
Gummy matters	4
Cellulose	20
Chlorophyll and wax	2
Caffeine	3
Tannin	10
Essential oil	0·75
Resin	3
Mineral matter (ash)	6
Moisture	7
Extractive matter	20·25
	100

Also a trace (·1 to ·2 per cent.) of boheic acid, a vegetable acid peculiar to tea. The amount of tannin found in green teas appears to be about half as much again as in black, and the former always yield less moisture, doubtless because of the harder fibre produced by the method of manufacture and the frequent use of a facing medium. A large percentage of moisture found in any sample would indicate improper condition. At the stage of final firing, tea is supposed to be desiccated as completely as possible, and it is then sealed up to exclude air entirely. It is, however, most liable to absorb moisture upon subsequent exposure. Caffeine (formerly known as theine) is the alkaloid of tea, and is identical with that of coffee, guarana, mate and kola nut. It is closely allied to theobromine, the alkaloid of cocoa, and also to uric acid. In large quantities it is a poison, but in smaller quantities it acts as a stimulant. It exists in greater percentage in Indian and Ceylon teas than in those from Java, and is lowest in China and Japan teas. Tannin is a hardening and astringent substance, and in large quantities impairs digestion. Prolonged infusion increases the amount extracted. The essential oil of tea is of a citron yellow colour; it is lighter than water and possesses the distinctive odour of tea. Extract varies from 26 to 40 per cent., and is no guide to quality. Ash averages 5·7 per cent., about half of which is soluble in water. About 8 per cent. of ash is proof of adulteration.

Commercial.—There is probably no article of large consumption the commerce in which has been so revolutionized during a single generation. In 1877, except to the initiated, tea meant China tea. India and Java were producing a little, but practically for use only in Great Britain and Holland. Formosa and Japan were beginning to attract attention in America, but China supplied the world, and almost entirely through the medium of the London market. The days of sailing ships from China had not entirely passed, and the steamers of the period were built for rapidity of transit to London. The Australasian colonies got their supplies direct, and part of the Russian supplies went by the caravan routes.

By 1907, however, the greatly increased production in India and Ceylon, with the willingness of many nations to drink such teas, in preference to those of China, had left to her Russia as a customer for nearly half her export of the article, a proportion rapidly diminishing, as that country too turned in the direction of using the stronger varieties.

China and Japan have hitherto been regarded as the chief producers of tea, and the reputed large domestic consumption of those Mongolian peoples has led to assumptions of vast internal productions. There exist absolutely no data, and it is doubtful whether such can ever be gathered, for forming trustworthy estimates. In both of those countries tea is grown principally in a retail manner, and much of it simply for family consumption. The country cultivator has, as a rule, only a small area—perhaps a corner of his farm or garden—planted with tea, the produce of which is roughly sun-dried and cured in a primitive manner. Any surplus not needed for the family is sold in its sun-dried state to the collector, who takes it to the hong, where it is fired, blended and packed for exportation. Excluding therefore from any record the quantities produced for internal consumption in China and Japan (that from the former alone has been estimated at a total of 2,000,000,000 lb), the following are the acreage and production of the world as taken from the latest recorded statistics available in 1908:—

	Acreage under tea.	Production. lb	
China	...[1]	188,371,000	quantities exported only.
„ . . .	(Brick tea for Tibet)[1]	19,000,000	
Japan	121,202[2]	39,778,000	
Formosa . . .	79,858	20,300,000	
India	531,808	240,411,000	
„ (Burma) .	1,498[2]	3,249,000	
Shan States .	(mostly pickled tea)[1]	16,000,000	
Ceylon	390,000	170,527,000	
Java	45,000	26,215,000	
Natal	5,000	2,750,000	
		726,601,000	

The quantity from China includes about 16,000,000 lb imported from India, Ceylon and Java, and worked up with China teas into bricks and tablets.

China. The modern developments of production and consumption have rendered the subject of China tea one of subordinate interest, except to students of commercial evolution. In several of the earlier editions of this work very ample details are furnished regarding the same, with many interesting pictorial illustrations of the processes of production. The conservative tendencies of the Chinese people have prevented them adopting the modern methods of extensive cultivation based on scientific principles, and the manipulation of crops by machinery in place of hand labour. Consequently, their export trade has been for many years a diminishing one. Of the exported quantity referred to above, only 81,000,000 lb were the ordinary black tea known to the English consumer (collectively described in the United States of America and Canada as "English Breakfast

China black tea.

[1] Areas unascertained. [2] Official figure, but accuracy doubtful.

Tea"). Out of that total, Great Britain consumed only about 5,000,000 lb, against a consumption of 126,000,000 lb of China tea in 1879. Green tea is represented by 28,000,000 lb, and this went chiefly to the United States of America, to Central Asia and to North Africa. The remainder, 80,000,000 lb, is brick and tablet tea sent entirely to Asiatic and European Russia. The method of compressing tea into tablets or bricks is unfamiliar in western Europe. It doubtless arose from the necessity of reducing bulk to a minimum for conveyance by caravan across the great trade routes of Asia, and now that the railway and the steamship have supplemented more primitive methods of transit, the system is still continued to meet the wants of the consumer who would not recognize his tea in any other shape. The preparation of the tea in the requisite form has, however, largely left Chinese hands. The Russians have themselves established several important factories at Hankow, which is the chief seat of this industry, and to which place they import in large quantities tea-dust and small broken tea from India, Ceylon and Java. Those are freely used in the preparation of small tablets, compressed to such a condition of hardness as to resemble wood or stone, and commonly passed round as currency in certain districts of Russia. Of a somewhat different nature is the brick tea prepared chiefly at Ya-chou in the province of Ssu-chuan for overland transit to Tibet, to investigate the commerce in which Mr James Hutchison, M.A., was sent in 1906 as a special commissioner for the Indian Tea Cess Committee. This tea is mostly prepared from exceedingly rough leaf, including even bush prunings, which would not be plucked for manufacturing purposes in India or Ceylon. It is "panned," rolled, fermented and divided into various classes or qualities. It is then steamed and placed in a moulding frame of wood to compress it into the size and shape of brick wanted. The bricks are wrapped in paper bearing hong marks, or some writing in Tibetan. For transit they are packed twelve together in hides sewn up while moist, which contract to make a strong tight package of 60 to 70 lb weight. These bales are carried on the backs of coolies for great distances across very high passes into Tibet, and the trade is estimated at an average of 19,000,000 lb per annum, of which 8,000,000 is a subsidy from the emperor of China to the Tibetan monasteries.

China green tea. ***Bricks and tablets.*** ***Brick tea for Tibet.***

The Japanese production is almost entirely green tea for North American use. It is prepared in two distinctive classes named by the final process of manufacture applied in each instance, viz. basket-fired, *i.e.* dried over a hot stove in a basket, and pan-fired, *i.e.* in machine-made pans. The industry is a declining one, because of change in the American taste, and the area under cultivation has diminished by nearly 20 per cent. in the ten years since 1896. The mulberry leaf for the more profitable silk trade has taken its place. The export production of the island of Formosa is limited to a particular class of tea termed Oolong, practically all produced for the United States of America. It is scarcely known in England save by experts. The Tea Cess Committees of India and Ceylon have both sent representatives in recent years to study the manner of growth and production, but in neither country has there been so far any successful attempt to produce commercially tea of the class. A radical difference exists in connexion with the method of growth, in that the plants are never grown from seed, but are always propagated from layerings. Soil, situation and climatic conditions have doubtless much influence on the peculiar character of the tea produced. The manufacturing methods are elaborate and careful, and the produce has in its choicest qualities a particular delicacy and bouquet possessed by no other variety of tea.

Japan. ***Formosa Oolong.***

As the planting, productive and manufacturing processes of India may be taken to be generally representative of Ceylon and Java also, and therefore of the tea of modern commerce in most lands outside of China and Japan, the methods followed will be described with some fullness.

Indian tea trade.

A rich and exuberant growth of the plants is a first essential of successful tea cultivation. This is only obtainable in warm and moist localities where rains are frequent and copious. The climate indeed which favours tropical profusion of jungle growth—still steaming heat—is that most favourable for the cultivation of tea, and such climate, unfortunately, is often trying to the health of Europeans. It was formerly supposed that comparatively temperate latitudes and steep sloping ground afforded the most favourable situations for planting, and much of the disaster which attended the early stages of the tea enterprise in India is traceable to this erroneous conception. Tea thrives best in light friable soils of good depth, through which water percolates freely, the plant being specially impatient of marshy situations and stagnant water. Undulating well-watered tracts, where the rain escapes freely, yet without washing away the soil, are the most valuable for tea gardens. Many of the original Indian plantations were established on hill-sides, after the example of known districts in China, where hill slopes and odd corners are commonly occupied with tea-plants.

Climate.

The methods described hereafter are those generally followed in India and Ceylon in the manner of the most modern application, but variations must take place according to district and elevation. Propagation is from seed only. The seed is rather larger than a hazel nut, with a thicker and darker shell and perfectly spherical shape. When ripe (about the month of November) the seeds are placed a few inches apart in carefully prepared nurseries, which are watered, shaded and weeded till the regular rains of May and June admit of the shading being removed. The seedlings should then be 6 ins. to 8 ins. high and ready to plant out in the fields. These are prepared by cutting down and burning the jungle, which is afterwards hoed, lined and staked in parallel rows running both ways. The intervals of planting vary, but 4½ ft. by 4½ ft. is a very common distance. Pits 15 ins. to 18 ins. deep are dug for each plant, and refilled loosely—then the seedlings are carefully placed in them. With favourable weather they should be 15 ins. to 18 ins. high by the end of the first year. Sometimes the plants are grown in the nursery for a whole year or more and put out during the cold weather. After two years' growth the bushes should be 4 to 6 ft. high. They are then cut down to about 8 ins. and are allowed to grow again up to 2 or 3 ft. before, towards the end of their third year, being plucked regularly. The object of this cutting down is to cause the bushes to spread out and cover the ground area usually allowed to each plant, *i.e.* about 20 sq. ft. The yield in the third year is small, probably less than ½ oz. finished tea per bush. At 7 to 10 years old, when in full bearing, 4 to 5 oz. would be considered a good return. The annual production per acre from matured plants was in 1906 in the principal producing districts of India:—

Planting out.

Darjeeling	317 ℔
Assam	402 „
Travancore	452 „
Sylhet	515 „
Cachar	542 „
Dooars	569 „

Individual estates of large area gave as much as 1280 ℔ per acre. In Ceylon the average yield per acre was 440 ℔, but there are verified records of 996 ℔ per acre within the year from an estate of 458 acres. On the same property an area of 100 acres gave 1100 ℔ per acre on the average over a period of 18 years.

Cultivation.

Cultivation in the northern parts of India is done by digging over the soil—locally termed hoeing—once in the winter quarter and six times in the nine months of the harvesting season. To keep an estate clean and in good cultivation it requires to be gone over every six weeks. The labourers being barefooted, a spade is useless, so a "khodalee" or hoe (much like a very heavy and long-bladed garden Dutch hoe) is used. It is raised well over the head and dropped forcibly into the ground, then pulled towards the wielder to turn over the soil. In southern India and Ceylon clean hand-weeding is the method of cultivation, almost no hoeing being done. In northern India the plucking season begins in April. During the first flush (*i.e.* the breaking out of young green shoots after pruning and the rest of winter) the bush is encouraged to grow by leaving 3 or 4 fully developed leaves after removing the tip of the shoot. It takes about 6 weeks to remove entirely the whole of the first and succeeding flushes, going round the estate once a week. In the second flush two leaves only are left. In the third and fourth flushes only one large leaf, and after that—say during October, November and part of December—no soft leaf growth is left that can be harvested in good order. In northern India, where the weather in the winter months is cold and dry, growth practically ceases, and then the whole area is pruned and cut down to about 16 ins. high all over, but in Travancore and Ceylon it grows continuously and is only pruned when found expedient at intervals of 15 months to 2 years. In certain cases of high-lying estates, where the growth is slow, it is allowed to run 3 years from pruning. The finest teas are produced at high elevations in Darjeeling and Ceylon and in the plains of Assam, but the quality from individual estates varies much from season to season, and even from week to week. There are at times marked differences between the produce of adjoining estates, with apparently identical conditions of soil and situation. Tea grows and thrives from about sea-level in the tropics to 7000 ft. in more temperate conditions. The life of a well-cared-for bush has been estimated at 50 years, in spite of its numerous enemies. Those include mites, termites (or white ants), thread blight, grey blight, caterpillars (naked or in bags) and caterpillars armed with stinging hairs to protect them, and borers, red and black, some of which eat the core out of the wood, while others content themselves with eating only the bark.

During recent years in India a new development has taken place in planting tea upon what are termed "bheels,"—lands resembling to a great extent the peat bogs of Ireland and Scotland. When opened up by an elaborate and complete system of drainage, they have been found to possess the power of producing enormously heavy yields, and it is from such estates that the greatest yields in India have come.

In Ceylon, and to some extent in India, the careful and systematic application of chemical manures, compounded on scientific lines, has been found to increase largely the yield of leaf, and much interplanting of nitrogen-producing growths has been done with a view to restoring to the soil the most necessary constituents.

Manufacture.

In the early days an attempt was made to copy the Chinese methods, and the various processes were manual. Now, from the plucking stage onwards, almost everything is done by machinery. During the season of yield the flushes are plucked every 7 to 10 days, and, as a rule, in India the opening bud and two leaves below it are plucked. To take more than this would be considered coarse and less would be fine plucking. These are of course quite immature, the longest rarely being one inch in length. The lower leaves on the young shoots are too old and hard to manufacture into tea. The plucking is done by women and children, and is now practically the only part of the work where the tea is touched by hand. The plucking season continues in some districts of India till December. As they are plucked, the green leaves are thrown into baskets, and twice daily the pluckings are taken into the factory. They are then spread out thinly on trays or racks made of bamboo, canvas or wire netting, under cover, for some 18 or 30 hours (according to the temporary weather conditions) to wither, after which they are in a soft, flaccid condition ready for rolling. On a successful wither the amount of the tea ferment or enzyme is dependent. The object of rolling is to crush the leaves and to break their cells so as to liberate the juices. The leaves are passed repeatedly through a machine driven by steam or other power giving a rotary motion, the operation occupying about 40 to 60 minutes. The next process is familiarly termed fermentation, but is really an oxidation of the leaves. Should the leaf be intended to be cured as green tea, the fermenting process is omitted and some other processes applied, but in India very little green tea is manufactured. Many people still cherish the antiquated belief that black and green teas are grown upon different varieties of the tea-plant, which is quite a mistake, the difference being merely one of preparation. After being rolled, the leaves are spread out in layers of 1 to 2 ins. thick in a cool house, and left to undergo the chemical action resulting from their condition. This process is checked after from 2 to 3 hours, according to climatic conditions. A further brief rolling to close up the open leaves is followed by the first firing, which is effected by subjecting the leaves to the gradual action of hot air up to a temperature of 240° F. Various applications of the same system are in use, but the most popular is to place the leaves on trays of wire network in a high temperature for about twenty minutes, after which they are firm and crisp. Up to this point of the manufacture the leaf has been in the stalk, the leaves and bud being unseparated. They are now broken apart and sorted by mechanical sifters into the various grades or qualities, which are described as Orange Pekoe, Pekoe, Pekoe Souchong and Souchong, each of which names represents approximately the leaf-bud and the three lower leaves. In addition to these four classes, out of each are sifted all the smaller fragments of leaf broken in the process of manufacture, which are termed *Broken* Orange Pekoe, &c. These broken grades are frequently objected to by the consumer, under the impression that they are inferior in quality, but in the opinion of experts, the more the leaf is broken up, the better is the liquor upon infusion. Upon completion of the sifting, the tea is again fired, and while warm it is packed tightly into lead-lined chests, and the lead covers completely soldered over it, so that it may be kept perfectly air-tight until required for use.

Machinery.

The machinery in use is very varied in character, and it has been evolved principally by practical planters of a mechanical turn. Many estate superintendents have begun their careers as engineers, and it is not unusual for a large estate, or group of estates, to have one member of the European staff who is a qualified engineer. The motive power is generally a steam engine, but the greater economy and facility of oil engines have led to their fairly wide adoption. Where water power is available, turbines of a variety of types are in use. The machines to be driven are air-fans, rollers, roll-breakers, sifters, cutters and packers, and there are besides numerous types of driers or desiccators. The names associated with the most successful and widely used machines are those of the Messrs Jackson (makers, Marshalls of Gainsborough) and Mr S. C. Davidson, of the Sirocco Works, Belfast. The production of the empty boxes for packing, called chests or half-chests, is in itself a large industry. The heavy old-fashioned country-made packages are rapidly being replaced by light-tared boxes made from several thicknesses of veneer pressed closely together, most of which come from Russia.

Green tea.

A production temporarily in excess of the world's demand of several years ago, led to the offering of bonuses for the production in India and Ceylon of green teas, with a view to lessening the black tea output. The methods adopted were successful, and after some vicissitudes a satisfactory business has been established, especially with the United States of America and Canada. The methods of producing this tea are not so complicated as those followed in China and Japan. The principal difference from the manner described of making black tea lies in the omission of the withering and fermenting, and the substitution for those of a steaming or panning process. The effect of either is to destroy the possibility of fermentation by subjecting the leaf, as soon as it is plucked, to a brief period of great heat. This completely destroys the ferment or enzyme, and renders it possible to conserve the tea in what is really nearer its natural form than the black tea that is so well known to the consumer.

Tea Consumption.—The following table gives particulars relative to the principal consuming countries, from which it will be seen that Great Britain and its English-speaking dependencies are the great consumers:—

Tea Consumption of Chief Consuming Countries in 1906.

China . . . . Unknown
Japan . . . . ,,

	Total per Annum.	Rate per Person of Population.	Rate of Duty per lb.
	lb		
United Kingdom . . .	269,503,000	6·17	5d.
Russia	135,400,000	0·94	Certain kinds free for Asiatic Russia or over Asiatic frontier —others 2¾d. to 1s. 11½d.
United States of America	84,842,000	0·89	Free.
Dominion of Canada. .	23,969,000	4·34	,,
Commonwealth of Australia.	27,959,000	6·88	,,
Dominion of New Zealand	6,141,000	6·5	,,
Germany	6,354,000	0·11	(If British grown) 1·35d.
France	2,428,000	0·06	9d. (surtax 2¾d. if not direct import).
Holland	7,874,000	1·45	2½d.
South Africa	7,572,000	1·4	4d. (Natal tea free)
Argentine Republic . .	2,870,000	0·49	4½d.
Tibet.	19,000,000	13½ lb	High, but uncertain.
India (estimated) . . .	7,240,000	?	Free.
Burma (average about).	19,000,000	?	,,
Persia (average about) .	6,000,000	?	4½d. to 7d.
	626,152,000		

The countries of smaller consumption absorbed about 25,000,000 lb, but there is a considerable excess in the returns of production over those of consumption. This arises partly from the latter relating in certain instances to an earlier period, and partly from the fact that much of the yield of 1906 was afloat or undespatched at the close of that year.

The following table gives the approximate rates of duty per English lb during 1907 in places not referred to above:—

Austria and Hungary . . . . 9¾d. imported by sea, by land 11d.
Bahamas . . . . . 6d.
Barbados . . . . . 3d. and 20% ad val.
Belgium . . . . . Free.
Bermuda . . . . 6¼% ad val.
Brazil . . . . 50% ad val.
British E. Africa . . . . . 10% ad val.
British Guiana . . . . 8d.
Bulgaria . . . . . 4½d. plus 4½d. excise and octroi 1½d.
Chile . . . . 9d.
Cyprus . . . . . . 4d.
Denmark . . . . 4d.
Ecuador . . . . . 2½d.
Egypt . . . . 8% ad val.
Fiji . . . . 6d.
Gibraltar . . . . Free.
Greece . . . . . . 1½d.
Grenada . . . . . 6d.
Honduras . . . . 2½d.
Italy . . . . 11d.
Jamaica . . . . . 1s.
Lagos . . . . 1d.
Malta . . . . Free.
Mauritius . . . . 3d.
Mexico . . . . . . 6d.
Morocco . . . . . 10% ad val.
Newfoundland 33% ad val.
Nigeria . . . . . . 10d.
Norway . . . . . 1s.
Peru . . . . 65% ad val. and 10%.
Portugal . . . . . 2s. 0½d.
Rumania . . . . 3½d. and 4½d. excise.
Sierra Leone . 10% ad val.
Spain . . . . 6½d. (if transhipped in a European port 1s. 7½d. cwt. additional).
St Helena . . . . Free.
Straits Settlements . . . . . Free.
Sweden . . . . . 3d.
Switzerland . . In receptacles weighing less than 5 kilos. 1¾d. over 1·10d.
Tobago and Trinidad . . . 6d.
Turkey . . . . . . 11%.
Uganda . . . . . 10%.
Uruguay . . . . . 5¾d.
Venezuela . . . 6d.

The rate per head of population within the United Kingdom has not increased much during recent years, and in the Australasian colonies it has apparently fallen greatly as compared with recorded averages of 12 lb per head in Victoria and 9 lb in New South Wales in 1884. The modern statistics of the commonwealth may be more accurately kept, and there may be less waste in use, but it is not supposed that there is any diminution in the free use of the beverage which has always characterized the antipodean colonist. One important factor in keeping down the amount per person is the substitution in use, which for a generation has been in progress, of the stronger teas of India and Ceylon for the old-fashioned weaker produce of China. The progressive increase in the consumption of tea in Great Britain and Ireland during 50 years from 1836 to 1886 is shown in the table below. The dotted line represents the average monthly consumption in each year; the fluctuations in price of good sound China congou are traced by the black line; and the years in which reduced customs duty came into operation are indicated along the base. From 1860 onwards, the amount of Indian tea entered for home consumption is shown in monthly average by a black column. This column brings out the remarkable fact that the Indian tea alone consumed in 1886 equalled the consumption of all kinds in 1860, and was double the quantity of all kinds in 1836. The table, however, shows merely the general development of consumption, but a similar one on next page, bringing the figures up to 1907, shows the gradual and almost total displacement of China tea by that grown in the English dependencies. In both, the price fluctuations and fiscal changes are shown that their effect upon consumption may be judged. The prices below are the annual averages for all Indian teas sold in the London public auction market during the years stated. Lowness of price has not been the only factor in increasing the rate of consumption. The lean years and the fat years of the general labour market always tell, and the low range

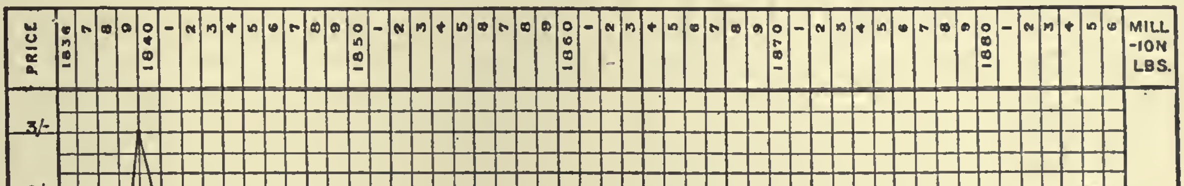

FIG. 5.

of prices for sugar during recent times has undoubtedly assisted in increasing the amount available for expenditure on tea. In Russia tea costs more to the consumer than in any country where modern transit by railway and steamer exists. The reason is the enormous proportion of the retail selling price which is exacted by the government by way of duty. But in return the government, with a paternal care for its people, makes absolutely certain that the tea reaches their hands as pure and unadulterated as when it first entered the country. Russian tea has always had a high reputation—largely a sentimental one, however. The quantity taken by the country is very large, but when spread over the enormous population the rate of consumption per person is not great. The extreme poverty of the great body of the people and the high price doubtless explain this. The method of use differs much from that followed in England. The samovar, or urn for boiling the water, is always much in evidence. Tea that makes a dark, strong liquor is preferred—not that such liquor is used, but that the greatest possible quantity of tea-coloured water may be drained from the teapot by refilling it over and over again from the samovar. The tea is generally drunk from glasses and while very hot, with a liberal addition of sugar and a flavouring of lemon. The method of use is

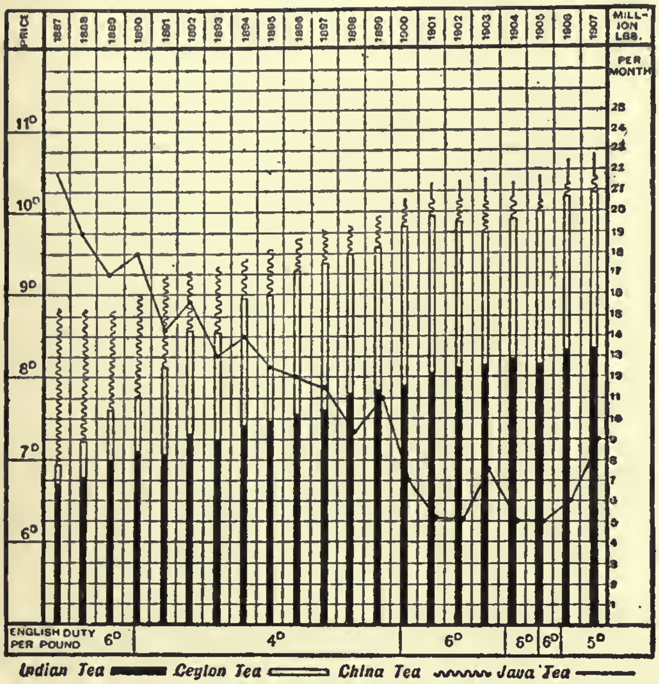

FIG. 6.—Diagram showing the alterations in the relative proportions of different growths of tea consumed during the 21 years ended the 31st of December 1907; the variations in the London average prices for Indian teas, and the changes in the English rate of duty. Vertical lines show the average monthly consumption in Great Britain and Ireland in millions of pounds. The diagonal line shows the average price per ℔ of all Indian tea sold in the London public auctions.

probably a more healthy one than that followed in many parts of the United Kingdom, where strong infusions of powerful teas are indulged in too frequently.

The United States of America and the great colonial dependencies follow generally the English way of using the beverage.

France, considering that it is England's nearest neighbour, has a remarkably small tea consumption: ·06 ℔ per person per annum, or about $\frac{1}{100}$th only of the English rate. The increase in consumption there has been so small that it probably arises mainly from the increasing number of English and English-colonial visitors that spend portions of each year in the country.

Germany, and the Germanic peoples, take slightly more per person, but the statistics are rather indefinite. Holland, in Europe, comes next to England, and uses principally the product of her dependency Java. The other nations of Europe are very small consumers. Some of the peoples of eastern Europe take their tea with an admixture of rum. In Morocco and generally throughout North Africa there is a considerable demand for green tea, which is drunk hot out of glasses, the liquor being almost saturated with sugar and strongly flavoured with mint.

In China and Japan tea is generally drunk without any other qualifying or flavouring addition. Exceedingly delicate teas can therefore be used unimpaired. In Japan the ceremony of serving tea has, among the better classes, been raised to a high art, which the girls have to study at school for protracted periods.

In Mongolia and other parts of Central Asia tea is made into a kind of soup, somewhat on the lines of the following written regarding tea in Tibet by Colonel Waddell in his book *Lhasa and its Mysteries*. Writing of the Tibetan he states: "As a beverage he drinks, all day long, cupfuls of hot buttered tea, which is really a soup or broth made by boiling tea-leaves with rancid butter and balls of dough, and adding a little salt, and straining—a decoction which was invariably nasty to our taste, though no doubt it is wholesome; for it is not merely a stimulating hot drink in the cold, but overcomes the danger of drinking unboiled water in a country where the water supply is dangerously polluted."

Geography of Tea.—The successful commercial production of tea on a large scale is confined to a strictly limited area enclosed by about 40° of latitude (5° S. to 35° N.) and about 73° of longitude (67° to 140° E.), while the consumption shows itself to a large extent to have strictly geographical limitations. The southern hemisphere ranks lightly in the matter of consumption, the only other country worth mentioning there besides the Australasian and Cape dependencies being Argentina. A straight line of latitude runs through all of these. In the northern hemisphere (excluding the races who consume their own produce) the material consumption of tea is in regions lying 40° N. and above it, but here there is an interesting subdivision to be made. In the United States of America and Canada, in some portions of Europe and of Asia, and along the north of Africa, there is a free use made of green or unfermented teas with pale, pungent infusions. The demand for such, as a general rule, lies principally in lower latitudes, while the farther north the consumer lives he seems to require more of the black or fermented tea of India, Ceylon or China, with the dark, thick, heavy liquor its infusion produces.

Transportation.—In the early part of the 19th century the tea shipped to England was destined to supply many countries, as London was then, and until comparatively recent times, the common warehouse and central market for the world, and England the common carrier. Throughout that century fairly steady and rapid progress was shown—especially in its earlier periods—in the trade from China, which reached its maximum in 1879. And it is here that some of the romance of commerce comes in. As the trade grew in importance, the advantages of rapid transit for the tea of new season's production began to be appreciated, and the slow and stately progress of the old East Indiaman became out of date. A type of vessel, specially designed for the rapid carrying of tea from China to England via the Cape of Good Hope, was introduced, known as the "China Clipper," and the competition was always keen as to which ship should make the most rapid passage. This culminated in the year 1866, when nine ships sailed almost simultaneously from Foochow, three of them crossing the bar in company. These three were all built by the same builders in Greenock, and came in ahead of all the others, making the long voyage of fully 16,000 m. in 99 days. They each docked in a separate dock in London upon the same day, and all within two hours of each other. The two leading ships had not seen each other for 70 days and met off the Lizard, from which point they ran a neck-and-neck race before a strong westerly wind, with every rag of canvas set.

The opening of the Suez Canal in 1869 soon changed the course of all trade with the East, and in a few years the sending of tea per sailing ship round the Cape of Good Hope was a thing of the past. Romance was no more, although there was extreme competition in building steamers with great power and speed to land their cargoes rapidly by the new route. This reached its height in 1882, when the s.s. "Stirling Castle" made the phenomenal run, for those times, of 28 days from Woosung to London.

But England, which formerly supplied almost everything to her own colonies and to many foreign countries besides, has, under the modified conditions of abundant steam tonnage everywhere, become less and less of a distributive country. Consequently, direct shipments are made now from the countries of production to those of consumption. America gets its tea largely through its western seaboard from China, Japan, Ceylon and India, while not a little is reaching it of recent years by steamers running direct from those countries via the Suez Canal to New York. The Australian demand is fed by steamers from Calcutta and Colombo, with some additions direct from China and Java.

The extensive Russian trade is now largely conducted over the Siberian railroad, and this, next to the transit to London, represents the largest volume of tea traffic passing in one channel. This route has displaced much of the protracted caravan business through Manchuria and Mongolia. A most interesting and adventurous episode in connexion with Russian trade was the effort repeated over several successive years by the late Captain Wiggins to convey tea entirely by sea from Chinese ports around the North Cape and through the Kara Sea to the Obi and Yenisei rivers. When successful, the journey, although about seven times the mileage of the old direct caravan route, took four months instead of eighteen, and was of course much less expensive.

The only protracted camel or mule caravan journeys remaining in connexion with the tea trade are those in Persia and Morocco, where the conservatism of race delays the introduction of even wheel roads, not to mention railways.

Tea Adulteration.—In the earlier days of the tea trade, adulteration, especially prior to importation, was frequent, because the prices obtainable made it remunerative. Now, intentional adulteration is practically non-existent, chiefly because of the fact that in the places of production the price obtainable is so low that any possible adulterant would be too costly to collect. Most countries have a close check upon this at the time of importation, and the customs authorities in Great Britain submit to analysis all samples of a doubtful character. Impure teas are not permitted to pass into consumption, but the quantity condemned after analysis as unfit for food in the year 1906 was 41 packages, out of a total of 317,000,000 lb.

Effect on Health.—The effect of the use of tea upon health has been much discussed. In the days when China green teas were more used than now, the risks to a professional tea-taster were serious, because of the objectionable facing materials so often used. In the modern days of machine-made black tea, produced under British supervision, both the tea-taster and the ordinary consumer have to deal with a product which, if carefully converted into a beverage and used in moderation, should be harmless to all normal human beings. There has been constant controversy as to whether China tea is better than that of other growths, but the verdict first of all of Great Britain, and subsequently of all the other large consuming countries, has relegated the produce of the Celestial Empire to a very subordinate position. A limited section of medical opinion has recommended China tea for reasons of health, and undoubtedly the inferior strength it possesses reduces the risk arising from improper use, but it also reduces the stimulating and comforting effects the ordinary tea-drinker hopes to experience. Next to water, tea is the beverage most widely in use throughout the world as regards the number of its votaries as well as the total liquid quantity consumed.

Bibliography.—The statistics given are taken as far as possible from official returns, and where such are unavailable they have been carefully compiled from reliable data.

The literature of tea is very copious, but scattered in pamphlet form to a great extent. In addition to the books quoted in the text, the following may be mentioned:—Bontekoe, *Tractat van het excellenste Kruyd Thee* (The Hague, 1679); Sylvestre Dufour, *Traités Nouveaux et Curieux du Café, du Thé, et du Chocolat* (2nd ed., Lyons, 1688; translation of 1st edition by John Chamberlayne, London, 1685; translations also in Spanish and Latin); J. G. Houssaye, *Monographie du Thé* (Paris, 1843); Robert Fortune, *Three Years' Wanderings in China* (London, 1847); Id., *A Journey to the Tea Countries of China* (London, 1852); S. Ball, *Tea Cultivation in China* (London, 1848); J. J. L. L. Jacobson, *Handboek voor de Kultuur en Fabrikatie van Thee* (3 vols., 1843); S. A. TEA-CADDY, a box, jar, canister or other receptacle for tea. The word is believed to be derived from *catty*, the Chinese pound, equal to about a pound and a third avoirdupois. The earliest examples that came to Europe were of Chinese porcelain, and approximated in shape to the ginger-jar. They had lids or stoppers likewise of china, and were most frequently blue and white. The English kilns at first imitated them, but speedily devised forms and ornament of their own, and there was hardly a ceramic factory in the country which did not compete for the supply of the new fashion. But tea-caddies were not for long confined to procelain or faïence. They were presently made in a great variety of materials, and in an equal variety of shapes. Wood, pewter, tortoise-shell, brass, copper and even silver were employed, but in the end the material most frequently used was wood, and there still survive vast numbers of Georgian box-shaped caddies in mahogany, rosewood, satinwood and other choice timbers, often mounted in brass and delicately inlaid, with knobs of ivory, ebony or silver. Although many examples were made in Holland, principally of the earthenwar of Delft, the finer varieties enamelled, enriched with ciphers, and emblazoned with heraldry, the tea-caddy was a typically English product. As the use of the jar waned and that of the box increased, the provision of different receptacles for green and black tea was abandoned, and the wooden caddy, with a lid and a lock, was made with two and often three divisions, the centre portion being reserved for sugar. Chippendale's caddies in Louis Quinze fashion were delightful, with their claw and ball feet and exquisite finish. On the whole the mahogany or rosewood caddy of the latter part of the 18th and the early years of the 19th century was, from the artistic point of view, the most elegant and satisfying. The wood was rich and well-marked, the inlay simple and delicate, the form graceful and unobtrusive. Even when it took the shape of a miniature sarcophagus, imitated from the massive wine-coolers of the Empire period, with little claw feet and brass rings, it was a decidedly pleasing object. The larger varieties were known as tea-chests. As tea grew cheaper it became less important that it should be kept constantly under the mistress's eye, and the tea-caddy gradually fell into desuetude. It has, however, never gone entirely out of use, though handsome examples are now most commonly regarded as ornaments or preserved in collections.

TEACH [Thatch or Thach], **EDWARD** (d. 1718), English pirate, popularly known as Blackbeard, is believed to have been born at Bristol. He is said to have gone out to the West Indies during the war of the Spanish Succession, to have engaged in privateering, and after the declaration of peace (1713) to have turned pirate, but he is not actually heard of in this capacity till the end of 1716. The following year he captured a large French merchantman, rechristened her "Queen Anne's Revenge," and converted her into a warship of forty guns. His robberies and outrages in the Spanish main, the West Indies, and on the coasts of Carolina and Virginia, quickly earned him an infamous notoriety. He made his winter quarters in a convenient inlet in North Carolina, the governor of which colony was not above sharing in the proceeds of his crimes, but the governor of Virginia at last despatched two sloops, manned from the British warships on the station, to cut him out. On the 22nd of November 1718 Lieutenant Maynard, commanding the attacking forces, boarded Teach's sloop, after a sharp fight, and himself shot the pirate dead. Teach seems to have been an ignorant ruffian. His personal appearance was remarkable. His nickname was due to his habit of tying up the ends of his long and bushy black beard with ribbon and curling them back over his ears. Johnson in his *General History of the Pyrates* gives his name as Teach, but according to the official records it was really Thatch or Thach.

TEAK,[1] the most valuable of all known timbers. For use in tropical countries it has no equal, and for certain purposes it is preferable to other woods in temperate climates also. Its price is higher than that of any other timber, except mahogany.[2] Great efforts have been made to find substitutes, but no timber has been brought to market in sufficient quantities combining the many valuable qualities which teak possesses.

The first good figure and description of the tree was given by Rheede,[3] the best modern picture being that given by Brandis.[4] The younger Linnaeus called it *Tectona grandis*. It is a large deciduous tree, of the natural order Verbenaceae, with a tall, straight but often buttressed stem, a spreading crown, and the branchlets four-sided with large quadrangular pith. It is a native of the Indian peninsula, Burma and Siam, and is also found in the Philippine Islands, in Java and elsewhere in the Malay Archipelago. In India proper its northern limit is 24° 40′ on the west side of the Aravalli Hills, and in the centre, near Jhansi, in 25° 30′ N. lat. In Burma it extends

[1] The Sanskrit name of teak is *saka*, and it is certain that in India teak has been known and used largely for considerably more than 2000 years. In Persia teak was used nearly 2000 years ago, and the town of Siraf on the Persian Gulf was entirely built of it. *Saj* is the name in Arabic and Persian; and in Hindi, Mahratti and the other modern languages derived from Sanskrit the tree is called *sag*, *sagwan*. In the Dravidian languages the name is *teka*, and the Portuguese, adopting this, called it *teke*, *teca*, whence the English name.

[2] The rate in the London market since 1860 has fluctuated between £10 and £20 per load of 50 cub. ft.

[3] *Hortus Malabaricus*, vol. iv. tab. 27, 1683.

[4] *Forest Flora of North-West and Central India*, Ill. t. 44.

to near Myitkyina, in lat. 25° 30′. In Bengal or Assam it is not indigenous, but plantations have been formed in Assam as far as the 27th parallel. In the Punjab it is grown in gardens to the 32nd.

Teak requires a dry tropical climate, and the most important forests are found in those districts of India where, during the summer months, heavy rains are brought by the south-west monsoon, the winter months being nearly rainless. In the interior of the Indian peninsula, where the mean annual rainfall is less than 30 in., teak is more scarce, and it thrives best with a mean annual fall of more than 50 in. The mean annual temperature which suits it best lies between 75° and 81° Fahr. Near the coast the tree is absent, and inland the most valuable forests are on low hills up to 3000 ft. It grows on a great variety of soils, but there is one indispensable condition—perfect drainage or a dry subsoil. On level ground, with deep alluvial soil, teak does not always form regularly shaped stems, probably because the subsoil drainage is imperfect.

During the dry season the tree is leafless; in hot localities the leaves fall in January, but in moist places the tree remains green till March. At the end of the dry season, when the first monsoon rains fall, the fresh foliage comes out. The leaves, which stand opposite, or only whorled in very young specimens, are from 1 to 2 ft. in length and from 6 to 12 in. in breadth. On coppice shoots the leaves are much larger, and not rarely from 2 to 3 ft. long. In shape they somewhat resemble those of the tobacco plant, but their substance is hard and the surface rough. The small white flowers are very numerous, on large erect cross-branched panicles, which terminate the branches. They appear during the rains, generally in July and August, and the seed ripens in the succeeding January and February. On the east side of the Indian peninsula, the teak flowers during the rains in October and November. In Java the plantations are leafless in September, while during March and April, after the rains have commenced, they are clothed with foliage and the flowers open. During the rainy season the tree is readily recognized at a considerable distance by the whitish flower panicles, which overtop the green foliage, and during the dry season the feathery seed-bearing panicles distinguish it from its associates. The small oily seeds are enclosed in a hard, bony, 1–4-celled nut, which is surrounded by a thick covering, consisting of a dense felt of matted hairs. The fruit thus formed is further enclosed in the enlarged membranous calyx, in appearance like an irregularly plaited or crumpled bladder. The tree seeds freely every year, but its spread by means of self-sown seed is impeded by the forest fires of the dry season, which in India generally occur in March and April, after the seeds have ripened and have partly fallen. Of the seeds which escape, numbers are washed down the hills by the first heavy rains of the monsoon. These collect in the valleys, and it is here that groups of seedlings and young trees are frequently found. A portion of the seed remains on the tree; this falls gradually after the rains have commenced, and thus escapes the fires of the hot season. The germination of the seed is slow and uncertain; a large amount of moisture is needed to saturate the spongy covering; many seeds do not germinate until the second or third year, and many do not germinate at all. Where the teak tree is associated with dense clumps of bamboo, natural reproduction is almost absent, except when the bamboo flowers and dies, and even then, if the dry bamboos and the resultant bamboo seedlings are not burnt, such young teak as may germinate are likely to be smothered at once.

The bark of the stem is about half an inch thick, grey or brownish grey, the sapwood white; the heartwood of the green tree has a pleasant and strong aromatic fragrance and a beautiful golden-yellow colour, which on seasoning soon darkens into brown, mottled with darker streaks. The timber retains its aromatic fragrance to a great age. On a transverse section the wood is marked by large pores, which are more numerous and larger in the spring wood, or the inner belt of each annual ring, while they are less numerous and smaller in the autumn wood or outer belt. In this manner the growth of each successive year is marked in the wood, and the age of a tree may be determined by counting the annual rings.

The principal value of teak timber for use in warm countries is its extraordinary durability. In India and in Burma beams of the wood in good preservation are often found in buildings several centuries old, and instances are known of teak beams having lasted more than a thousand years.[1] Being one of the most durable of Indian timbers, teak has always been used for buildings, particularly for temples, and in India it has been the chief timber employed for shipbuilding. When iron commenced to be extensively used for the last-named purpose, it was supposed that the demand for teak would decrease. This, however, was not the case, for the wood was for long very largely used in shipbuilding, and though its employment in war-vessels has diminished, it is still in very great demand for "liners" and similar ships. It is also used for furniture, for door and window frames, for the construction of railway carriages, and for many other purposes. White ants eat the sapwood, but rarely attack the heartwood of teak. It is not, however,

Teak (*Tectona grandis*).

proof against the borings of the teredo, from whose attacks the teak piles of the wharves in the Rangoon river have to be protected by a sheathing of metal.

Once seasoned, teak timber does not split, crack, shrink, or alter its shape. In these qualities it is superior to most timbers. In contact with iron, neither the iron nor the teak suffers, and in this respect it is far superior to oak. It is not very hard, is easily worked, and takes a beautiful polish. It has great elasticity and strength, and is not very heavy. The average weight of perfectly seasoned wood fluctuates between 38 and 46 ℔ per cub. ft.[2] Its weight, therefore, is a little less than that of English oak. Green teak timber, however, is heavier than water, so that,

[1] In one of the oldest buildings among the ruins of the old city of Vijayanagar, on the banks of the Tungabhadra in southern India, the superstructure is supported by planks of teakwood 1½ in. thick. These planks were examined in 1881; they were in a good state of preservation and showed the peculiar structure of teak timber in a very marked manner. They had been in the building for 500 years (*Indian Forester*, vii. 260). In the wall of a palace of the Persian kings near Bagdad, which was pillaged in the 7th century, two Americans found in 1811 pieces of Indian teak which were perfectly sound (Ouseley, *Travels in Various Countries of the East*, ii. 280, n. 67). In the old cave temples of Salsette and elsewhere in western India pieces of teak have been found in good preservation which must have been more than 2000 years old.

[2] At 44·8 ℔ per cub. ft. a load of 50 cub. ft. weighs a ton (2240 ℔), hence in the Burma ports a ton of teak timber is taken as equivalent to a load of 50 cub. ft.

unless thoroughly seasoned, the wood cannot be floated. In Burma, therefore, where the rivers are used to float the timber to the seaports, the method of seasoning teak by girdling has been practised from time immemorial. Girdling consists in making a deep circular cut through bark and sap into the heartwood, so as completely to sever communication between bark and sapwood above and below the cut. In teak, as in oak and other trees with well-marked heartwood, the circulation of the sap only takes place in the sapwood, and the girdled tree therefore dies after a few days if the operation has been effectually performed. But if even the smallest band of sapwood is left connecting the outer layers of wood above and below the girdle, the tree is not killed, and often recovers completely. The girdled tree is allowed to stand one or two years, and longer if a very large-sized tree. Being exposed to the wind and to the action of the sun, the timber of a girdled tree seasons more rapidly and more completely than that of a tree felled green. The teak produced in the presidencies of Madras and Bombay and in the Central Provinces is as a rule felled green, and even when dry it generally is a little heavier than the timber from Burma.[1] For a long time to come, the rivers of Burma and Siam will continue to afford the most convenient and most economical routes for the extraction of teak timber from those countries. Indeed, the forests drained by the Salwin and its feeders are not likely ever to be worked otherwise than on the present plan, under which the logs are floated singly over the rapids and are caught and rafted lower down, at the kyodan or rope station, 70 miles above Moulmein.

As already mentioned, teakwood contains an aromatic oil, which gives it a peculiarly pleasant smell and an oily surface when fresh cut. To this oil may probably with justice be ascribed its great durability. In Burma the oil is extracted from the timber on a small scale, to be used for medicinal purposes, by filling an earthen pot, which is placed inverted upon another, with chips of wood, and putting fire round it, upon which the oil runs down into the lower vessel.

According to the colour and texture of the wood, several varieties of teak are distinguished in India, Burma and Java; in the timber trade, however, these distinctions are of no importance. Teak, as well as other trees, when standing isolated, forms side branches far down the stem, and the wood of such trees is more knotty and wavy, and generally heavier and darker-coloured than that of trees which have grown close together in a dense forest. Apart from the manner in which the tree had grown up in the forest, soil, elevation and climate have a great influence upon the grain and the mechanical qualities of teak as of other timbers. Most of the larger logs brought to market have an irregular crack or hollow in the centre, which commences at the butt and often runs up a long way. There is little doubt that this is generally due to the action of the fires, which scorch and often destroy the bark of young trees. Such external injuries are apt to induce decay in the wood. Moreover, most teak seedlings which come up naturally are cut down to the ground by the fires of the hot season; some are killed, but many sprout again during the rains, and this is generally repeated year after year, until a sapling is produced strong enough to outlive the fire. Such saplings have a very large pith, which dries up, causing a hollow in the heart; or a piece of the old shoot killed by the fire is enclosed by the new wood, and this also is apt to give rise to a hollow.

The leaves of the teak tree contain a red dye, which in Malabar was formerly used to dye silk and cotton. Natives of Burma use the leaves as plates, to wrap up parcels, and for thatching.

In its youth the tree grows with extreme rapidity. Two-year-old seedlings on good soil are 5 to 10 ft. high, and instances of more rapid growth are not uncommon. In the plantations which have been made since 1856 in Burma, the teak has on good soil attained an average height of 60 ft. in 15 years, with a girth, breast high, of 19 in. This is between 16° and 18° N. lat., with a mean annual temperature of 78° F. and a rainfall of 100 in. In the Burma plantations it is estimated that the tree will, under favourable circumstances, attain a diameter of 24 in. (girth 72 in.) at the age of 80. Timber of that size is marketable, but the timber of the natural forests which is at present brought to market in Burma has grown much more slowly, the chief reason being the annual forest fires, which harden and impoverish the soil. In the natural forests of Burma and India teak timber with a diameter of 24 in. is never less than 100 and often more than 200 years old. In future, the timber grown in plantations and in forests under regular management may be expected to be much faster grown; and there is no ground for anticipating that rapidly grown timber will be less valuable than that of slow growth, which is at present brought to market.

Like the other trees of the dry deciduous forest, teak does not attain any extraordinary size. The trees are not generally more than 100 to 150 ft. high, even under the most favourable circumstances, and stems more than 100 ft. to the first branch are not often found. Exceptionally tall trees were measured in 1861 in the Gwaythay forest in Pegu, east of the Sitang river, on gneiss. The stems had 106 to 114 ft. to the first branch, with a girth, at 6 ft. off the ground, from 7 to 16 ft. Larger girths, up to 25 ft., are not uncommon.

The teak tree does not usually form pure forests. It is associated with bamboos and with a great variety of other trees, which have little market value, and, as a rule, thrives best in such company. Hence in the plantations established in Burma the object has been to raise forests of teak mixed with bamboos and other trees.

Most of the teak timber produced in India is used in the country. The produce of the forests of Travancore, Cochin, the Madras presidency, Coorg, Mysore, Bombay, Berar and the Central Provinces is all so consumed. Formerly there was a considerable export from the ports of the western coast—Malabar, Kanara, Surat and Broach—but the country at present requires all the teak which its forests can produce; indeed the demand is in excess of the supply, and considerable quantities are imported from Burma to Calcutta, Madras, Bombay and other Indian ports. Small quantities are still exported from the ports of the western coast to Arabia and the coast of Africa. The chief export is from Burma, principally from Rangoon and Moulmein. Of the other teak-producing countries, Java exports a little; there have also been exports from Saigon; and since 1882 Bangkok has sent considerable quantities to Europe. But the Burma coast is the chief source of supply at present. Rangoon was for a long time an important place for shipbuilding, teak being the chief timber used: between 1786 and 1825 111 European vessels were built at Rangoon, aggregating 35,000 tons. At the same time timber was exported, and, when the country was taken by the British in 1852, teak was the chief article of export. Moulmein became British territory at the close of the first Burmese war in 1826. At that time the place was a large fishing village, and it was mainly through the export of teak timber and the shipbuilding trade that it attained its present importance. From 1829 to 1841 upwards of 50,000 loads of teak timber were exported, and, in addition, 68 vessels were built during that period, aggregating 15,680 tons, and estimated to have required for their construction 24,000 loads of teak timber. The forests from which Moulmein first derived its supplies are situated on the Attaran river, a feeder of the Salwin. In 1836, however, timber began to come down from more distant forests, and in 1841 one-fourth only of the supply was brought from the Attaran forests.

The increase in the export of timber from the Burma ports was slow at first, but has gone on rapidly since Rangoon became a British port. Since that time the timber brought to the Burma ports has come from the following sources:—(1) from the forests in the British coast provinces, Pegu and Tenasserim; (2) from the forests in the former kingdom of Burma, floated to Rangoon down the Sitang and Irrawaddy rivers; (3) from the forests in the Shan states formerly tributary to Burma, from the Karenni country, and from western Siam, whence it is floated to Moulmein by the Salwin river.

The following table shows the figures of the imports and exports of British India for the years 1901–2 to 1905–6:—

	Imports.		Exports.	
	Cub. Tons.	Value Rs.	Cub. Tons.	Value Rs.
1901–2....	17,842	13,03,968	60,671	71,53,855
1902–3....	32,081	24,96,317	57,500	68,67,879
1903–4....	34,588	30,55,695	73,913	91,45,605
1904–5....	46,915	42,46,190	46,912	60,05,383
1905–6....	71,676	62,17,331	52,768	70,41,660
1906–7....	61,696	60,71,557	44,202	61,48,291
Average..	44,133	38,98,483 =£259,899	55,994	70,60,445 =£470,696

Nearly the whole of the imports came from Siam, and of the exports four-fifths were from Burma. The balance of the imports consisted of timber from Java, that of the exports of supplies sent from peninsular ports. Two-thirds of the exports went to the United Kingdom, the other chief markets being ordinarily Germany, Ceylon and Australia. The recent great increase in the general teakwood trade is evidenced by the fact that the imports increased in six years from 17,842 tons to 61,696 tons. But it is noticeable that, whereas in 1901–2 the timber exported very largely exceeded the imports, in 1905–6 and 1906–7 the imports were larger than the exports, evidence of the great increase in Indian demand for teak timber; and, in all probability, of the steady regular outturn of the Indian forests, in comparison with increased imports from Siam, where the forests are not, like those in Burma, under regular working plan, designed to give a permanent annual yield and avoid any danger of exhaustion of the forests.

In British India, including Burma, a large portion of the teak-producing tracts have since 1856 been placed under conservancy management with the object of preventing overcutting and maintaining a permanent and gradually increasing supply. This is the object of the working plans referred to. The area of teak forest

[1] It has been erroneously stated that the tree in Burma is tapped for its oil before felling.

available in India and Burma is considerable, and every endeavour is made to conserve it and increase its production. Similar measures have been taken in Siam under the advice of officers borrowed from British India; and in the teak-producing native states in the peninsula the necessity for careful management is now well understood. The teak plantations in Java had come into bearing by 1908 and it was expected that the teak areas in the Philippine Islands would be similarly developed. (D. Br.; J. S. Ga.)

TEAL (O.E. *tele*), a variety of duck, whose name is of uncertain origin, but doubtless cognate with the Dutch *Taling* (formerly *Talingh* and *Telingh*), and this apparently with the Scandinavian *Atteling-And* (Brünnich, *Ornithol. Borealis*, p. 18) and *Atling*. It seems impossible not to connect the latter with the Scottish *Atteile* or *Atteal*, to be found in many old records, though this last word (however it be spelt) is generally used in conjunction with teal, as if to mean a different kind of bird; and commentators have shown a marvellous ineptitude in surmising what that bird was.

The Teal is the *Anas crecca* of Linnaeus, *Nettion crecca* of modern ornithology, and the smallest of the European *Anatidae*, as well as one of the most abundant and highly esteemed for the table. It breeds in many parts of the British Islands, making its nest in places very like those chosen by the Wild Duck, *A. boscas*; but there is no doubt that by far the greater number of those that are taken in decoys, or are shot, during the autumn and winter are of foreign origin. While the female presents the usual inconspicuous mottled plumage of the same sex in most species of *Anatinae*, the male is one of the handsomest of his kind. His deep chestnut head and throat are diversified on either side by a line of buff, which, springing from the gape, runs upward to the eye, in front of which it forms a fork, one prong passing backward above and the other below, enclosing a dark glossy-green patch, and both losing themselves in the elongated feathers of the hind-head and nape. The back and sides of the body appear to be grey, an effect produced by delicate transverse pencillings of black on a dull white ground. The outer lanceolate scapulars have one-half of their webs pure white, forming a conspicuous stripe along the side of the back. The breast is of a pale salmon or peach-blossom colour, each feather in front bearing a roundish dark spot, but these spots lessen in number and size lower down, and the warm tint passes into white on the belly. The tail coverts above and below are velvety black, but those at the side are pale orange.

The teal inhabits almost the whole of Europe and Asia,—from Iceland to Japan,—in winter visiting Northern Africa and India. It occasionally occurs on the western shores of the Atlantic; but its place in North America is taken by its representative, *A. carolinensis*, the male of which is easily to be recognized by the absence of the upper buff line on the side of the head and of the white scapular stripe, while he presents a whitish crescentic bar on the sides of the lower neck just in front of the wings.

Species more or less allied to these two are found in most other parts of the world, and among such species are some (for instance, the *N. gibberifrons* of the Australian region) in which the male wears the same inconspicuous plumage as the female. But the determination of the birds which should be technically considered "Teals," and belong to the genus *Nettion*, as distinguished from other groups of *Anatinae*, is a task not yet successfully attempted, and much confusion has been caused by associating with them such species as the Garganey (*q.v.*) and its allies of the group *Querquedula*. Others again have not yet been discriminated from the Wigeons (*q.v.*), the Pintail-Ducks, *Dafila*, or even from the typical form of *Anas* (see Duck), into each of which genera the Teals seem to pass without any great break. In ordinary talk "Teal" seems to stand for any Duck-like bird of small size, and in that sense the word is often applied to the members of the genus *Nettopus*, though some systematists will have it that they are properly Geese. In the same loose sense the word is often applied to the two most beautiful of the family *Anatidae*, belonging to the genus *Aex* (commonly misspelt *Aix*)—the Carolina Duck of North America, *Ae. sponsa* (not to be confounded with the above-named *Anas carolinensis* or *Nettion carolinense*), and the Mandarin-Duck of China, *Ae. galericulata*. Hardly less showy than these are the two species of the subgenus *Eunetta*,—the Falcated Duck, *E. falcata*, and the Baikal Teal, *E. formosa*,—both from Eastern Asia, but occasionally appearing in Europe. Some British authors have referred to the latter of these well-marked species certain Ducks that from time to time occur, but they are doubtless hybrids, though the secret of their parentage may be unknown; and in this way a so-called Bimaculated Duck, *Anas bimaculata*, was for many years erroneously admitted as a good species to the British list, but of late this has been properly discarded. (A. N.)

TEANO (anc. *Teanum Sidicinum*), a town of Campania, Italy, in the province of Caserta, 21 m. N.W. of that town on the main line to Rome from Naples, forming conjointly with Calvi an episcopal see. Pop. (1901) 6067 (town); 13,505 (commune). It stands at the S.E. foot of an extinct volcano, Rocca Monfina (3297 ft.), 643 ft. above sea-level. The cathedral dates from 1530, but has many columns obtained from the ruins of the ancient town. There is a feudal castle built by the dukes of Sessa in the 15th century. Below the town on the S.E. is the old church of S. Paride.

The ancient Teanum Sidicinum (there is a Teanum Apulum, *q.v.*, in Apulia) was the capital of the Oscan tribe of the Sidicini which drove the Aurunci from Rocca Monfina. They probably submitted to Rome in 334 B.C. and their troops were grouped with those of Campania in the Roman army. Thus the garrison of Regium, which in 280 attacked the citizens, consisted of one cohort of Sidicini and two of Campanians. Like Cales, Teanum continued to have the right of coinage, and, like Suessa and Cales, remained faithful to Rome in both the Hannibalic and the Social wars. Its position gave it some military importance, and it was apparently made a colony by Claudius, not by Augustus. Strabo speaks of it as the most important town on the Via Latina, and only coming after Capua among the towns in the interior of Campania. It lay on the Via Latina, here joined by a branch road from Suessa, of which remains still exist, and which continued E. to Allifae. Remains of a theatre and an amphitheatre still exist, and some extensive baths, containing several statues, and some Roman dwellings, both some way below the modern town, were excavated in 1908. A tomb with a Christian mosaic representing the visit of the three kings to Bethlehem was found in 1907 (V. Spinazzola in *Notizie degli Scavi*, 1907, 697; E. Gabrici, *ibid.*, 1908, 399).

TEANUM APULUM, an ancient town of Apulia, Italy, on the road between Larinum and Sipontum, 18 m. E. of the former, at the crossing of the Fortore near the modern village of S. Paolo di Civitate. It was called Teate in earlier times, as appears from its numerous coins, which have Oscan legends. It submitted to Rome in 318 B.C., being then the chief town of Apulia. It was afterwards known as Teanum Apulum, and was a *municipium*. Some ruins and an old bridge over the Fortore still exist.

TEA-POY (Hindustani *tēpāī*), a small table, supported upon a tripod, or even upon four legs, for holding a tea-service or an urn. The word was also sometimes applied to a large porcelain or earthenware tea-caddy, and more frequently to the small bottles, often of Battersea enamel, which fitted into receptacles in the caddy and actually contained the tea.

TEAR, a drop of the liquid secretion of the lachrymal gland, constantly produced in a certain quantity and flowing through the nasal duct without notice, but, when stimulated by pain, emotion or artificial excitation, increasing so that it flows over the eyelids and runs down the cheeks and is the visible result of crying or weeping (see Eye). The O.E *teār*, *taer*, is represented in other Teutonic languages by Dan. *taar*; Swed. *tår*; Goth. *tagr*, &c. The O.H.G. was *zahar*; the mod. Ger. *Zähre* was formed from the M.H.G. plural *Zahere*. The commoner word in Ger. *Thräne*, cf. Du. *traan*, is closely allied. The original root is seen in Gr. δάκρυ, Lat. *lacrima*, *lacruma*, for *dacruma*, whence Fr. *larme*, and It., Sp., and Port. *lagrima*.

The generally accepted Indo-Germ. root is *dak-*, to bite, cf. Gr. δάκνειν, and Skt. *daç*, to bite, tears being "biting" or "bitter" things. The Du. *traan*, in the sense of tear-drop, was particularly applied to the blubber of whales reduced to oil by boiling, whence has come the tautological English "train-oil," often identified with the lubricant used for the wheels of railway trains. For the so-called "tear-vessels," which are properly small vases containing unguents, see LACRYMATORY.

"Tear" (O.E. *teran*), to pull apart violently, to rend, is, of course, a distinct word; it is cognate with Gr. δέρειν, to flay, pull off, and the root is seen in Gr. δέρμα, skin, whence "dermatology," "epidermis," &c.

TEASEL. Wild teasel is a common plant of the English copses and hedges, with a tall, stout, rigid, prickly stem, bearing large spreading opposite leaves, the midrib of which is prickly, and conspicuous oblong heads, the purplish flowers in which are subtended by very long, narrow, stiff, upright bracts. The plant is known botanically as *Dipsacus sylvestris*. Fuller's teasel, *D. Fullonum*, in which the bracts are hooked, is probably a cultivated form of the wild species; the dry heads are used to comb up the nap on cloth. The genus *Dipsacus* gives its name to the family *Dipsaceae*, to which also belongs the Scabious (*Scabiosa*), represented in Britain by several species.

TEATE MARRUCINORUM [mod. Chieti, *q.v.*], the chief town of the Marrucini, the whole of whose territory was placed under its municipal jurisdiction by the Romans, after the "Social War." It was thus a town of some importance. Under the church of SS. Pietro e Paolo and the adjoining houses are extensive substructures (in *opus reticulatum* and brickwork) of the 1st century A.D., belonging to a building erected by M. Vectius Marcellus (probably mentioned by Pliny, *H.N.*, II., 199) and Helvidia Priscilla. There are also remains of large reservoirs and of a theatre.

TEBESSA (the Roman Theveste), a town of Algeria in the department of Constantine, 146 m. S.E. of Bona by rail and 12 m. W. of the Tunisian frontier, on a plateau 2950 ft. above the sea. Pop. (1906) 5722. The modern town, which is within the walls of the Byzantine citadel, boasts nothing of interest save a church built out of the ancient ruins. The Byzantine walls, pierced by three gates, are in tolerable preservation. They are strengthened by numerous square towers. One of the gates is formed by the quadrifrontal arch of Caracalla, a rare form of construction. The arch, erected about A.D. 212, is in good preservation. A pair of monolithic columns, disengaged, flank each façade. An inscription on the frieze gives the history of its construction; it was built by two brothers as a condition of inheriting the property of a third brother. The most important ruins are those of the great basilica. This building, one of the finest Roman monuments in Algeria, bears evidence of having been built at various epochs; the earlier portions probably date from not later than the beginning of the 2nd century A.D. The basilica was partially destroyed by the Berbers in the 5th century, and was rebuilt in A.D. 535 by the Byzantine general Solomon, who surrounded it with a wall about 25 feet high, still standing. The main building, consisting of a nave with apsidal end and two aisles, was approached through a peristyle, which was surrounded by an arcade. Many of the columns of the basilica have fallen, but the bases of all are in their original positions. A quatrefoil chapel on the east side of the basilica is a Byzantine addition. The tessellated pavement which covers the basilica proper is in almost perfect condition. It is kept covered, for purposes of preservation, by a layer of earth. Next the basilica (and within the same enclosing walls) are the ruins of the forum, converted into a monastery in the 4th or 5th century, and regarded by Sir R. Lambert Playfair as the oldest known example of the *monasteria clericorum*. The whole of the basilica and its dependencies have been cleared and are kept in order by the *Service des Monuments historiques*, the principal work having been accomplished by Héron de Villefosse. Noteworthy among the buildings within the ancient citadel is a small tetrastyle temple, variously ascribed to Jupiter and Minerva, the portico supported by six monolithic columns of cippolino, four being in front. After the French occupation in 1842, the building was used successively as a soap factory, a prison, a canteen, a parish church, and, lastly, as a museum.

Theveste was founded towards the close of the 1st century A.D. In the succeeding century it was connected with Carthage by a great highway. In the 5th century, under Vandal dominion, it declined in importance. Refounded by the Byzantines in the 6th century, the city disappeared from history at the time of the Arab conquest of the country in the 7th century. In the 16th century the Turks placed a small garrison of janissaries in the place, but Tebessa continued to be but a small village until the establishment of French rule.

Nine miles from Tebessa are the extensive phosphate quarries of Jebel Dyr, where is also an interesting megalithic village.

See Sir R. Lambert Playfair, *Handbook for Travellers in Algeria and Tunis* (London, 1895), pp. 233–40, *Guides-Joanne, Algérie et Tunisie* (Paris, 1906).

TECHNICAL EDUCATION. The term now generally adopted to designate the special training of persons in the arts and sciences that underlie the practice of some trade or profession, is called "technical education." Schools in which this training is provided are known as technical schools. In its widest sense, technical education embraces all kinds of instruction that have direct reference to the career a person is following or preparing to follow; but it is usual and convenient to restrict the term to the special training which helps to qualify a person to engage in some branch of productive industry, and the instruction so provided is generally known as "technological instruction." This specialized education may consist of the explanation of the processes concerned in production, or of instruction in art or science in its relation to industry, but it may also include the acquisition of the manual skill which production necessitates.

General theory.

The terms "technical" and "technological" (Gr. τέχνη, art or craft) as applied to education, arose from the necessity of finding words to indicate the special training which was needed in consequence of the altered conditions of production during the 19th century. Whilst the changed conditions of production, consequent mainly on the application of steam power to machinery, demanded a special training for those who were to be engaged in productive industry, the prevalent system of education was not adapted to the requirements of these persons, and schools were wanted in which the necessary instruction could be obtained. Other circumstances resulting mainly from the application of steam power to machinery rendered technical education necessary. Production on a large scale led to a great extension of the principle of the division of labour, in consequence of which it was found economical to keep a man constantly engaged at the same kind of work, since the more he practised it the quicker and more skilful he became. Thus employed, the workman learned little or nothing of the process of the manufacture at which he assisted, or of other departments of the work than the particular one in which he was engaged, and his only opportunity of acquiring such knowledge was outside the workshop or factory in a technical school. The economy effected by the division of labour led to the extension of the principle to other industries than those in which machinery is largely employed. There are many trades in which manual skill is as necessary now as ever, but even in these the methods of instruction prevailing under the old system of apprenticeship are now almost obsolete.

Changed conditions of production.

In many industries, including trades in which machinery is not as yet extensively employed, production on a large scale has increased the demand for unskilled labour, numbers of hands being required to prepare the work to be finished by a few skilled artisans. Rapidity of execution is attained by keeping a workman at the same work, which after a time he succeeds in mechanically performing and continues to do until some machine is invented to take his place. In most trades, as formerly practised, the master

Apprenticeship.

employed a few apprentices who assisted him in his work, and who learnt from him to understand the details of their craft, so that, when the term of their apprenticeship was over, they were competent to practise as journeymen. But now the master frequently has neither time nor opportunity to instruct young lads, and the old relation of master and apprentice is changed into that of manufacturer and workman. In consequence of these altered relations between employer and employed, there has arisen an acknowledged want of properly trained workmen in a number of trades in which skilful hand work is still needed; and in these trades a demand has arisen for technical schools, or some other substitute for what was formerly done by apprenticeship, as a means of suitably training workmen and foremen. The ever-increasing competition in production has led to the employment, in many trades, of children to do work of a mechanical kind requiring little skill; but, whilst thus employed, these young people have little opportunity of learning those parts of their trade in which skill and special knowledge are needed; and when they are grown up, and seek higher wages, they are dismissed to make room for other children. Numbers of young people are thus thrown upon the labour market, swelling the percentage of the unemployed, who are competent to do nothing more than children's work, and to earn children's wages, and who know no trade to which they can apply their hands. To remedy this, by creating some substitute for the old apprenticeship, is one of the objects of a system of technical education; though in suitable trades an independent movement for reviving apprenticeship (*q.v.*) under improved conditions has also made some way.

A complete system of technical education should provide the necessary instruction for the different classes of persons engaged in productive industry. It is usual to divide these persons into three classes:—(1) workmen or journeymen; (2) foremen or overseers; (3) managers or masters.

Classes of workers. The industries in which they are employed may be grouped under four heads:—(1) those involving the use of extensive machinery, such as iron and steel manufacture, machine-making, the textile industries, and some of the chemical trades; (2) those which mainly require the use of hand tools, as cabinet-making, brick-work, plumbing, and tailoring; (3) those depending on artistic skill, as wood and stone carving, metal-chasing, enamelling, decorative work, and industrial designing generally; (4) agriculture in all its branches, and forestry. These industries will be referred to as manufactures, handicrafts, art industries and agriculture. The foregoing classification comprises groups which necessarily, to some extent, overlap one another. Every factory contains a carpenter's and smith's shop, and handicraftsmen of group (2) are required in every manufacturing concern. Whilst the industries in which hand labour is exclusively employed are becoming fewer and fewer, there are many trades which, owing to the frequent invention of labour-saving appliances, are passing gradually from the class of handicrafts to that of manufactures. In these trades, of which watch- and clock-making and boot- and shoe-making may be taken as examples, there is still a demand for goods largely if not entirely produced by hand work. In such trades, owing to the absence of facilities for instruction in the ordinary shops, there is a want of skilled hand labour which there is an increasing difficulty in satisfying, and to supply this want technical schools of different kinds have been established. Then, again, there are many branches of manufacturing industry which greatly depend for their success upon the designer's art, and it is necessary that the industrial designer should possess a knowledge of the processes of the manufacture in which his designs will be utilized, as well as of the properties and capabilities of the material to which they will be applied. Indeed, it is the possession of this knowledge which mainly distinguishes the industrial designer from the ordinary artist. To determine the best training for such designers is one of the problems of technical education. There are many trades, too, in which the handicraftsman and the designer should be united. This is the case in such industries as silversmith's and goldsmith's work. In these and other trades the true artisan is the artist and handicraftsman combined.

Manufactures and handicrafts. In order to reconcile some of the different views which are held as to the objects of technical education, it is necessary to keep in mind the broad distinction, above referred to, between the conditions of production on a large scale, as in those industries in which goods are manufactured by the use of extensive labour-saving machinery, and in those trades in which hand work is chiefly employed. Much of the diversity of opinion regarding the objects of technical education is due to the difference of standpoint from which the problem is regarded. The volume of the trade and commerce of Britain depends mainly on the progress of its manufacturing industries. It is these which chiefly affect the exports and imports. The aim of manufacturers is to produce cheaper and better goods than can be produced by other manufacturers at home or abroad; and technical education is valuable to them, in so far as it enables them to do so. It also helps to widen the area of productive industry, and to encourage varieties of activity which the free and unfettered conditions of competition tend unduly to restrict. On the other hand, the artisan engaged in hand industries looks to technical education for self-improvement, and for the means of acquiring that general knowledge of the principles and practice of his trade, which he is unable to obtain in the commercial shop. Hence the artisan and the manufacturer approach the consideration of the question from different sides. To the spinner or weaver who almost exclusively employs women to tend his machinery, or to the manufacturing chemist whose workpeople are little more than labourers employed in carrying to and fro materials, knowing little or nothing of the scientific principles underlying the complicated processes in which they are engaged, the technical education of the workpeople may seem to be a matter of little moment. What such manufacturers require are the services of a few skilled engineers, artistic designers or scientific chemists. From the manufacturer's point of view, therefore, technical instruction is not so much needed for the *hands* he employs in his work as for the *heads* that direct it. But in trades in which machinery plays a subsidiary part, technical teaching supplies the place of that instruction which, in former times, the master gave to his apprentice, and the workman is encouraged to attend technical classes with a view to acquiring that knowledge of the theory and practice of his trade, on the acquisition of which his individual success greatly depends. In the former class of industries, technical education is needed mainly for the training of managers; in the latter, for the training of workmen. Hence has arisen a double cry,—for the teaching of art and of the higher branches of science, with a view to their application to manufacturing industry, and for the specialized instruction in drawing, and in the scientific facts which help to explain the processes and methods connected with the practice of different crafts and trades. This double cry has led to the establishment of technical universities and of trade schools.

Foremen and managers. Owing to the conditions under which manufacturing industry is now carried on, it is difficult to select competent foremen from the rank and file of the workmen. The ordinary hands gain a very limited and circumscribed acquaintance with the details of the manufacture in which they are engaged, and have little opportunity of acquiring that general knowledge of various departments of work, and of the structure and uses of the machinery employed, which is essential to the foreman or overseer. It is in evening technical classes that this supplementary instruction, which it is the workman's interest to acquire and the master's to encourage, can be obtained; and it is from the more intelligent workmen who attend these classes that masters and employers will select as foremen those students who are found to possess the essential qualifications. The history of invention shows how frequently important improvements in machinery are made by the workman or minder in charge of it, and adds weight to the arguments already adduced for giving technical instruction to persons of all grades employed in manufacturing industry. To these advantages of technical education, as affecting the workmen themselves as well as the progress of the industry in which they are engaged, must be added the general improvement in the character of the work produced, resulting from the superior and better-trained intelligence of those who have had the benefit of such instruction.

It will be seen from the foregoing that a complete system of technical education must make provision for the training of those who are to be occupied as journeymen or foremen in different branches of trade or industry, and also for those who aim at becoming managers or masters or heads of manufacturing firms, scientific advisers or professional engineers. As technical education necessarily implies specialized teaching, the curriculum and methods of instruction adopted in the elementary and secondary schools, where students receive their preliminary training, are matters closely related to any scheme of technical instruction, and the trend of educational opinion is in favour of associating the general instruction given in those schools with the specialized teaching of the technical institutions. Indeed, it is daily becoming more difficult to draw any hard-and-fast line between professional and general education. It is now universally recognized that the foundations of technical instruction must be laid in the elementary and the secondary schools, and many of the changes which have been made in the organization of those schools had their origin in the requirements of technical institutions.

Professional and general education.

A short survey of the methods adopted in different countries to provide the specialized teaching applicable to different pursuits, and of its relation to the general school system of those countries, will serve as a fitting introduction to the consideration of the legislative and other changes which have gradually been made in the British school system with a view to modern industrial conditions. The study of foreign systems of education is serviceable, as showing the relation of such systems to the industrial needs of each country and to the genius and character of the people. In the organization of technical education in England, full advantage has been taken of foreign experience, although no attempt has been made to imitate too closely foreign methods. Detailed information as to what has been done abroad is found in the published reports of the several English commissions which have been appointed to inquire into the subject, and in the valuable series of special reports issued from the Board of Education. From these reports, which show how varied have been the attempts to adapt school training to modern industrial requirements, certain general principles may be inferred, which are equally applicable to the conditions under which the trade and commerce of different countries is now carried on.

Study of foreign systems.

These general principles may be briefly enunciated as follows:—

1. The education of all persons who may expect to be occupied in some form of productive industry may be considered as consisting of two parts, (*a*) general, (*b*) special.

General principles.

2. The general education is the preliminary training provided in elementary and secondary schools, and the curriculum of those schools should be varied so as to have some reference to the future pursuits of the pupils.

3. The special or supplementary instruction should be adapted to the requirements of different grades and classes of workers, and to different trades or occupations as practised in different localities.

A complete system of technical education would afford facilities of training adapted to every kind and grade of industry; but, owing to the complexity of the problem, such a system is nowhere to be found. In every country the scheme of education and method of instruction have varied from time to time, as the conditions regulating trade and industry have changed. But recently in all civilized countries, the effort has been made to provide a general and specialized education adapted to different pursuits for each of these great classes of workers: (1) operatives, (2) foremen and overseers, (3) masters and managers.

1. *Workmen.*—Many attempts have been made to provide a substitute for apprenticeship, but hitherto with no great success. Two classes of workpeople have to be considered—(1) those engaged in manufacturing industries, and (2) those engaged in handicraft industries. The education of all classes of workpeople begins in the public elementary schools; and, in view of the future occupation of the children, it may be taken for granted that primary instruction should be practical, and should include drawing and elementary science. It should indeed be closely associated with manual training, consisting of workshop exercises and field work in the case of boys in urban and rural schools respectively, and of instruction in the domestic arts in the case of girls. The lessons in drawing and in elementary science should form part of the manual training, and the school curriculum should be unified so that all the subjects of instruction should be grouped together as parts of an organized system. The desired diversity should be found in the different kinds and grades of manual work. Reading, writing and arithmetic would be taught incidentally in close connexion with the practical exercises. In nearly every country of Europe, and in the United States, the trend of education practice is in this direction. In France, Belgium, Holland and Sweden handicraft instruction is generally included in the curriculum of elementary schools. Rudimentary science is also taught in nearly all the primary schools of Europe. Modelling is taught both to boys and girls in many Continental schools; and in Sweden "sloyd" (Sw. *slöjd*, manual dexterity, cf. Eng. "sleight"), a system of manual training, in which simple and useful articles, especially of wood, are constructed with the fewest possible tools, is taught with considerable success to children of both sexes.

Elementary education.

In Germany and Switzerland, there exists an excellent system of evening continuation schools, known as *Fortbildungs-* or *Ergänzungs-Schulen*, in which the instruction of the children who leave school before fourteen, and of those who leave at that age, is continued. In all these schools drawing is taught with special reference to local industries. In England great progress has been made in recent years in developing evening classes in which the pupils' elementary instruction is continued with a view to the specialized teaching provided in the technical school. The teaching in these continuation schools is generally varied according as the pupil is occupied in trade or office work, and the practice is becoming general of requiring him to pass a qualifying examination to secure admission to classes in technology. It will be seen, therefore, that the training of most workpeople, and of nearly all those who are engaged in manufacturing industry, consists of:—(1) primary teaching in elementary schools; (2) practice in the factory or shop, supplemented by further elementary teaching; (3) evening instruction in technology.

Continuation schools.

In all the principal towns throughout Europe evening classes have been established for teaching drawing, painting and designing, and the elements of science in their application to special industries. The instruction, however, is less practical than that provided in the corresponding schools in England. The classes abroad are mainly supported by the municipalities, by the chambers of commerce, by industrial or trade societies, by county boards, and in some cases by the fees of the pupils. They receive little or no support from the state. They are well attended by workpeople of all grades, who are encouraged by their employers to profit by these opportunities of instruction. In England evening technical instruction is more systematically organized than in any other country. It is under the general direction of the Board of Education, and of the City and Guilds of London Institute.

The Board of Education prescribe the conditions under which grants are paid to schools providing technical instruction. In former years these grants were paid on the results of the examination of individual students; but this method of apportioning state aid has been almost entirely abandoned. The Board still hold annual examinations in science and art and in certain branches of applied science; but the more specialized examinations in technology and trade subjects are held annually by the City and Guilds of London Institute, through its department of technology. These latter examinations are utilized by the Board, and the certificates granted on the results are recognized in the appointment of teachers. The technical schools in which these classes are held are under the direct control of the local educational authorities, and are largely supported by grants from local rates. Year by year a larger share of responsibility is being thrown upon the local authorities, with a view to encouraging greater variety of instruction and further adaptation of the teaching to local needs. The Board continue, however, to indicate the range of subjects to be taught in preparation for their annual examinations, and the City and Guilds of London Institute issues each year a programme containing suggested courses of training in nearly a hundred trade subjects.

Evening technical classes.

In the evening classes in science, art and technology, which have been established throughout the United Kingdom, the workman or foreman engaged in any manufacturing industry has the opportunity, by payment of a very small fee, of studying art in all its branches, science theoretically and practically, and the technology of any particular industry. Provided his early education enables him to take advantage of this instruction, no better system has been suggested of enabling workmen, whilst earning wages at an early age, to acquire manual skill by continuous practice, and at the same time to gain a knowledge of the principles of science connected with their work and explanatory of the processes of the manufacture in which they are engaged.

For those engaged in handicraft trades this evening instruction is equally valuable, and not only in England, but equally in other parts of Europe, there exist evening trade schools in which the workman is able to supplement the "sectional" practice he acquires in the shop by more general practice in other branches of his trade. In Vienna, for example, and elsewhere in Austria, there are found practical evening classes for carpenters, turners, joiners, metal-workers and others. Throughout Europe schools for weaving, with practical work at the loom and pattern-designing, have existed for many years.

Trade schools. To provide a training more like the old system of apprenticeship, schools have been established in many parts of Europe and in the United States which are known as professional, trade or apprenticeship schools (*écoles professionelles, écoles des apprentis, Fachschulen*). The object is to train workmen; and the pupils, after completing their course of instruction in such a school, are supposed to have learnt a trade. The school is the substitute for the shop. In such a school the pupils have the advantage of being taught their trade systematically and leisurely, and production is made subsidiary to instruction. Under such an artificial system of production, the pupil is less likely to acquire excellence of workmanship and smartness of habit than in the mercantile shop, under the strain of severe competition. Moreover, the cost of maintenance of these schools renders it impossible to look to them as a general substitute for apprenticeship. By sending into the labour market, however, a few highly trained workmen, who are absorbed in various works and exert a beneficial influence on other workmen, these schools serve a useful purpose. Schools of this kind have been tried with more or less success in different countries. In Paris there is the well-known École Diderot for the training of mechanics, fitters, smiths, &c.; and similar schools have been established in other parts of France. For many years a society of Christian Brethren has directed a large school situated in the Rue Vaugirard, Paris, in which different trades are taught. All the secular and general instruction is given gratuitously by the brothers, and in the several shops attached to the school skilled workmen are employed, who instruct the pupil apprentices, and utilize their labour. This system combines many of the advantages of shop work and school work, but it depends financially for its success upon the religious spirit which actuates its promoters and supporters. The Artane school, near Dublin, is conducted on somewhat similar principles, but is intended for a lower class of children. In Austria, particularly in the rural districts, there are numerous day schools for the training of carpenters, joiners, turners, cabinetmakers, workers in stone and marble, in silver and other metals, &c. Schools of the same class are found in Germany, Italy and Holland, and schools very similar in character have been organized to a limited extent in England. The demand that called them into existence in other parts of Europe and in America has been felt in the United Kingdom. The difficulty of securing for apprentices in a commercial shop systematic training in handicraft has led to the establishment of a few trade schools which receive children from the elementary school about the age of thirteen for a three years' course of instruction. In these schools the time is about equally divided between ordinary school subjects and the practice of some handicraft, such as cabinet-making, upholstery, waistcoat-making, millinery. Parents are encouraged to allow their children to receive this further education by the offer of free teaching and maintenance grants. Such schools, however, must be regarded as educational experiments, to be superseded if found necessary by reason of changes in the conditions under which the trade is practised. Any system of technical education, however, should be sufficiently elastic to permit of such experiments and of the introduction of types of instruction to meet special and even temporary needs. It is only in certain cases that apprenticeship schools can be said to answer satisfactorily the purpose for which they have been established. Where a new industry, especially in rural districts, has to be created; where decaying industries need to be revived; where machinery is superseding hand work, and, owing to the demands for ordinary hands, there is a dearth of skilled workmen; where through the effects of competition and other causes the trade is carried on under conditions in which competent workmen cannot be properly trained in the ordinary shop,—in these cases, and in various art industries, an apprenticeship school may prove to be the best means of training workmen and of advancing particular trades. Generally, an apprenticeship school should be looked upon as a temporary expedient, as a form of relief applied at the birth of a new industry or to meet some special conditions under which a trade is practised. The proper training school for workmen is the factory or shop.

In the United States there are only a few schools which have been specially organized with a view to the training of workmen for special trades. The line between technical and general education is not very clearly defined in any of the states' schools. It is also difficult to give any such general review of the system of education in America as can be presented in connexion with France or Germany or Italy, owing to the fact that each separate state has its own organization, over which the Federal government exercises no direct control. In none of the states is technical education differentiated by class distinctions to the same extent as in continental countries. The ambition of every workman is to become a master, and this general ambition gives rise to an enthusiasm for education among all classes, which does not exist to the same extent in any other country. In the United States are found evening technical schools and schools of design for those who have passed from the common schools into commercial work; but the desire for further instruction is so marked that many of those who have received only an elementary education endeavour, by working during the vacations, or by other means, to save enough money to attend the higher technical schools, and so acquire the necessary skill and knowledge to improve their position in the factory or workshop.

Training of foremen. 2. *Foremen.*—The foreman must be familiar with the various branches of work he is to overlook; and the training which the workman receives in the factory or shop affords him but scanty opportunities of obtaining this general knowledge. The foreman needs also a generally superior education. How then are foremen to be trained? The problem is somewhat easier than that of training workmen, because the number required is fewer. The variety of schools in Europe devoted to this purpose is very great. There are three distinct ways in which foremen are being trained.

(*a*) The evening technical classes in Britain and on the continent offer to ambitious workmen an opportunity of acquiring a knowledge of other departments of the trade than those in which they are engaged, as well as of the scientific principles underlying their work. These classes serve the double purpose of improving the workpeople and of affording a means of discovering those who are best fitted to occupy higher posts.

(*b*) Special schools have been established for the training of foremen. There are many schools of this kind in which selected boys are received after leaving the higher elementary or secondary school. The best known are those at Châlons, Aix, Nevers, Angers and Lille in France. These schools are intended for the training of foremen in engineering trades. They are state institutions, in which practical mechanical work in the shops is supplemented by theoretical instruction. The first of these schools was founded in 1803. The course lasts three years, and the students spend from six to seven hours a day in the workshop, and are trained as fitters, founders, smiths and pattern-makers. As in all such schools, saleable goods are produced, but, as production is subordinated to instruction, the school does not bind itself to deliver work at a given date, and therefore does not compete with any manufacturing establishment. The students on leaving these schools are competent at once to undertake the duties of foremen and draughtsmen. At Komotau, Steyr, Klagenfurt, Ferlach and many other places schools have been established on somewhat similar principles. In Germany there are special schools for the training of foremen in the building trade, which are chiefly frequented in the winter, and numerous schools are found in all parts of the continent for the training of weavers. At Winterthur in Switzerland a school has been established the main purpose of which is the training of foremen. In Italy there are numerous technical institutes, the object of which is to train young men for intermediate posts in industrial works. In London, the Finsbury technical college of the City and Guilds of London Institute has a day department, the main purpose of which is the training of youths as foremen, works managers, &c.; but in this school the character of the instruction deviates considerably from that given in French schools, and aims rather at preparing youths to learn, than at teaching them their trade.

(*c*) A third method adopted for the training of foremen is by encouraging selected children of the ordinary elementary schools to continue their education in schools of a higher grade of a technical character. It is thought that, by developing to a higher degree the intelligence and skill of those children who show aptitude for scientific and practical work, they will be able, when they enter the shop, to learn their trade more quickly and more thoroughly, and to acquire that general knowledge of their work, and to exhibit those special aptitudes, which may qualify them for the position of foreman or overseer. The education given in these schools, although having some bias towards the future career of the pupil, is disciplinary in character, and consists of the subjects of primary instruction further pursued,—of drawing, modelling, science, mathematics and manual exercises. The curriculum is varied according to local requirements, the technology of the staple industries forming in many cases part of the instruction. Such schools, under varied forms, have been established in most European countries, some of the best examples of them being found in Paris, Lyons, Reims, Rouen, and in other towns of France. One of the oldest of these schools is the École Martinière at Lyons. The school was founded in 1820 by a bequest from Major-General Martin, who had fought against the English under Tippoo Sahib. In this school, in which the education is gratuitous, as in nearly all the higher elementary schools of France, instruction is given in drawing, modelling, chemistry, mechanics and physics, in the working of wood and iron, and in German and English in addition to the subjects of an ordinary school education. Surveying is also taught to some of the pupils, and the instruction generally is of a very practical character. The students visit factories under the guidance of the masters, and on their return write out full descriptions of their visits. The school hours are from seven till eleven in the morning and from one till seven in the afternoon. The boys from this school rapidly obtain places in the commerical and industrial houses of Lyons, and many of them, after a time, succeed in obtaining high positions. A very similar school, on more modern lines, has been established at Reims, and is accommodated in a building especially adapted to the purpose. In this school instruction is directed towards the staple industries of the district, namely, weaving, dyeing and engineering. There are many other similar schools in France, the object of which is to give the children of artisans and small shopkeepers a higher practical education in order to fit them to occupy the posts of foremen, overseers and superior clerks in manufacturing and commercial firms. In Germany the *real* schools, in which Latin is not taught, known as *Ohnelatein Realschulen*, have very nearly the same objects as the higher elementary schools of France. The instruction in these German schools is not so practical as in the schools of France. Drawing is always well taught, and the schools generally contain good chemical laboratories, as well as collections of physical apparatus and museums. From the pupils of these schools the ranks of foremen are largely recruited. They receive no special trade instruction, but the general training is so arranged as to qualify them for higher posts in industrial works. The cost of this higher education seldom exceeds £3 per annum. In Bavaria there is found a type of school called *Industrie-Schule*, which serves very well for the training of engineers and industrial chemists, who aim at occupying intermediate posts, and desire to enter upon commercial work at an earlier age than students attending a university or technical college. The instruction in these *Industrieschulen* is largely practical, but is combined with some amount of literary and linguistic training. Some of the students proceed to the technical university, but the majority find posts as foremen or overseers soon after completing their school course. In most of these schools, as well as in the chief intermediate commercial schools, the exit certificate exempts a lad from two of the three years' compulsory military service, and this regulation, to which nothing corresponds in England, is an incentive to parents to allow their children to receive higher instruction, which operates very forcibly in largely increasing the number of well-educated youths in Germany.

Manual training schools in U.S.

A special feature of the education provided in the United States is what is known as the "manual training" school. This is a school admirably adapted for the training of foremen, although not especially intended for any particular industrial class. The manual training school is a secondary school in which a large part of the time is given to workshop exercises. The whole subject of manual training is more scientifically developed in some of the states of America than in any European country. The school is pervaded by the kindergarten spirit, and leads up, without break of continuity, to courses of instruction given in the higher technical colleges. The movement in favour of manual training in the United States is general and extends even to the private schools where youths are prepared for the university. At the same time, the purely practical teaching is invariably combined with scientific and literary instruction. In these, as in other schools, the principle is fully recognized that the primary aim of education is to make citizens and not tradesmen. It is difficult to take any one manual training school as typical of others, seeing how the curriculum varies in different states. The practical work includes exercises in carpentry, joinery, wood-turning, wood-carving, forging, foundry-work, machine fitting, stonework, and weaving and appropriate exercises for girls. The general idea underlying the scheme of instruction in these schools is that the teaching must be educative till the age of fifteen, and should then, and only then, develop into specialized and professional training.

Training of managers and masters.

3. *Masters.*—Some of the best schools for the training of future masters, managers, engineers, manufacturers and industrial chemists are found in Germany and Switzerland, and are known as technical high schools. Schools of a similar character are found in other countries.

In Germany the *technische Hochschule* or Polytechnicum is an institution of university type in which the education has special reference to industrial purposes. In many respects the teaching coincides with that given in the universities. The chief distinction consists in the arrangement of courses of instruction in the several departments, in the admission of students having a non-classical preliminary training, and in the absence of certain faculties found in the university and the addition of others. It is not correct to say that the technical high school is a professional school as distinguished from the university; for the faculties of law, medicine and theology give to the university as distinctly a professional character as the faculty of engineering gives to the technical high school. Nor can it be said that the scientific studies at the universities are less practical than at the technical high school. For, whilst workshops for instruction in the use of tools are found in very few of the German high schools, the laboratories for the practical study of chemistry and physics are as well equipped at some of the German universities as at the technical high schools. At the same time, engineers of every description, architects and builders, besides a great number of manufacturing chemists, find in the technical high school the scientific and special training which the future lawyer or physician, and in many cases the industrial chemist, seeks in the university.

German universities and technical high schools.

In some of the large cities—in Berlin, Vienna and Munich, for instance—the two institutions co-exist; and in certain cases, in which a very special training is required to fit a youth for his career, the German student, after spending three or four years at a technical high school, passes on to another institution, such as a dyeing school, in which his studies are further specialized with a view to his future work.

Taking the technical high school of Munich as a type of other similar institutions, we find that it consists of seven departments:—(1) the general; (2) the civil engineering; (3) the building; (4) the mechanical engineering; (5) the industrial chemical; (6) the agricultural, and (7) electrical technology. In other institutions there are architectural, pharmaceutical and mining schools. The programme of the Munich school gives a list of about 200 different courses of instruction distributed over the several departments. A separate professor is engaged to lecture on that particular subject with which he is specially conversant, and the number of such professors attached to a technical high school is very large. In the engineering department there are several distinct courses of lectures under the direction of professors who are experts in their special subject. The largest of all these institutions is that of Berlin, which was completed in 1884 at a cost of about £450,000. It is situated in what was a suburb of Berlin, and is generally known as the Charlottenburg Institution. It includes departments for the highest specialized instruction in nearly all branches of technology. Other schools in Germany are less complete, but most of them have one or more departments which are specially organized with a view to the highest grade of technical instruction. Both in the universities and in the technical high schools facilities for scientific research are provided, and the students are encouraged to undertake original investigations. The technical high schools are now placed on the same educational platform as the universities and have the power to confer the degree of Doctor of Engineering on students fulfilling the required conditions.

Higher technical training in France.

In France, the institutions in which the highest technical instruction is given are concentrated in the capital. There are a large number of provincial colleges such as the École Centrale at Lyons, the École des Mineurs at St Étienne and the Institut du Nord at Lille, where the education is somewhat more practical, but where the mathematical and scientific teaching is not carried to so high a point. Several of the French provincial colleges in which the higher forms of technical instruction are well developed became in 1898, under the law of 1896, separate universities. The École Centrale of Paris, in which the majority of French engineers who are not employed in the government service are trained, is a rare instance of an institution for higher technical instruction which is self-supporting and independent of government aid. Other special institutions in Paris, some of which are associated with the university of Paris, are the École des Mines, the École des Ponts et Chaussées, and the Collège de France, an old foundation in which facilities are afforded for the highest scientific research.

In Switzerland and elsewhere.

In Switzerland the federal polytechnic of Zurich is in many ways similar to the schools of Germany and Austria. Italy has three superior technical institutes—one at Milan, one at Turin and one at Naples, in which technical education is given on the same lines as in German polytechnic schools. Holland has an excellent institution at Delft, which was opened in 1864. In each of the state universities of Belgium there is a faculty of applied science, and degrees are granted on a course of training in science and technology; and in Russia the imperial technical school at Moscow is a high-class engineering school in which the theoretical studies are supplemented, to a greater extent than in the German schools, by workshop practice. It will be seen, therefore, that in nearly all European countries, instruction in engineering in all its branches and in chemical technology has become a recognized part of a university course, and that the faculty of applied science has been so enlarged as to provide technical education of the highest grade.

Some of the best schools for the higher technical instruction—for the training of masters and of those who are to occupy the position of managers in engineering and industrial works—are found in the United States. On leaving the secondary school, the American student may go at once into business: or he may proceed to a college, with a four years' course of general instruction; or he may enter a professional or technical school. Some students prolong their education by taking the general course before proceeding to the technical institution. As in the lower, so in the higher grades of instruction, the distinction between general and technical education is not very clearly defined. There are some institutions devoted almost exclusively to professional training; whilst in others the engineering faculty exists side by side with other faculties of university rank. The general interest in higher education which is shown by the desire of students of all classes to obtain it, in many cases at considerable individual sacrifice, and by the value which masters and employers attach to a college-trained youth, is partly due to the large proportion of pupils from the ordinary schools who proceed to the secondary or high schools. It is estimated that the pupils between the ages of fourteen and eighteen in attendance at these schools constitute at least one per cent. of the entire population of the United States. In several of the American institutions known as colleges, but not easily distinguishable from the universities, courses of general or technical instruction are provided of all intermediate grades, but above that given in the high schools. In addition to these there are some well-known institutions which provide courses of professional and general instruction of the highest grade under professors of eminence and distinction, and facilities for research which are not surpassed in any German university or technical high school. To the foundation and maintenance of these schools wealthy citizens have given or bequeathed enormous sums of money, and they further enjoy the proceeds of the sale of lands which were set apart under the Morrill Act of 1862 to give assistance to institutions providing instruction in agriculture and the mechanical arts. Several colleges whose work was mainly literary took advantage of this act to establish scientific and technical courses in order to secure the income to be obtained by compliance with its provisions.

Higher technical training in United States.

Without entering into great detail, it may be said that the schools providing advanced technical instruction may be grouped under three headings: (1) those which are free from state or government control and are maintained from funds arising out of endowments and students' fees, such as the Massachusetts Institute of Technology and the Stevens Institute of Technology, Hoboken; (2) schools which form part of, or are affiliated to, the universities, which are equally independent of public control, such as Columbia University, New York, and the Sibley College of Mechanical Arts, Cornell University; (3) schools and colleges attached to state universities, receiving grants from the state, such as the universities of Illinois and Michigan.

Contributions from private sources towards the establishment and equipment of these institutions are far in excess of those in any other part of the world. Between the years 1890 and 1901 these contributions amounted to about £23,000,000.

The American universities, with which the technical institutions are in many cases closely associated, differ from those in the United Kingdom in their examinations for degrees. In this respect they have adopted the practice of the German and other continental universities. The examinations are almost uniformly conducted by the teachers. The external examiner is practically unknown. This system allows considerable freedom to the teacher, and is said by competent judges to be attended with excellent results. In many of the states, particularly in the east, even the matriculation, or entrance examination, is being superseded by a system known as the "accrediting" system of the secondary or high schools, where the students receive their general education. According to this system, the schools are inspected by the professors of the university, and those in which the equipment, the courses of instruction, and the method of teaching are found to be satisfactory, are included in a list of "accredited" or approved schools, and the pupils of such schools, who produce a certificate of having satisfactorily attended the prescribed course of study, are admitted to the university without passing any entrance examination. An advantage of this system is that it brings the professors of the university into direct relationship with the schools in which the students receive their preliminary training, and closely connects the instruction provided in the school with the higher and more specialized teaching of the university.

The widespread appreciation of the advantages of the higher education among all classes of the American people, and the general recognition among manufacturers, engineers and employers of labour, of the value to them, in their own work, of the services of college-trained men, has largely helped to increase the number of students in attendance at the universities and technical institutions, and to encourage in every state the foundation of schools for advanced professional training.

The institutions in which the highest technical instruction is provided are those devoted to the teaching of engineering in all its branches, including mining engineering, and of chemistry in its application to manufacturing industry; besides schools of agriculture and forestry and schools of design.

Of these the Massachusetts Institute of Technology at Boston is the most typical. It was founded in 1859 with a view to supplying a complete system of industrial education, supplementary to the general training of other institutions. In 1861 an act was passed incorporating a body of persons for the purpose, *inter alia*, of aiding in the advancement of science in its application to the arts, agriculture, manufactures and commerce. The institute offers thirteen distinct courses. Of these, eight are devoted to engineering, including naval architecture; four to chemistry, physics, biology and geology, and one to preparation for professional teaching. In 1904 there were 183 instructors on the permanent staff of this institution. As indicating the practical character of the teaching in this and in other similar schools, it should be noted that the railway companies co-operate in making provision for tests on a large scale, and in permitting the use of locomotives on their line for the purpose of giving practical training to the students.

At Columbia University, New York, the school of applied science was established in 1864, and consists of a fairly complete school of technology with a four years' course of instruction. An interesting department at Columbia is the professorial school for the study of education and the training of teachers. The importance of manual training is recognized by the fact that the professor of this subject has a seat in the faculty of applied science. Two schools of observation and practice are maintained—the Horace Mann School and the Experimental School. The former comprises three departments, a kindergarten, an elementary and a high school. The experimental school is under the immediate direction of the professor of the theory and practice of teaching. The facilities provided for the professorial and technical training of teachers are one of the most valuable features in the educational system of the United States.

Higher technical instruction in Britain.

In England there is a growing tendency to associate technical with secondary education. The central technical college of the City and Guilds of London Institute, was an institution established exclusively for the purpose of providing the highest grade of engineering education. In this respect it compared more nearly than any other institution with the technical high schools of Germany. The Royal School of Mines, connected with the Royal College of Science, was a similar institution, providing the highest teaching for mining engineers. In Birmingham, Leeds and Sheffield, schools of applied science were established under the names respectively of the Mason College, the Yorkshire College of Science, and Firth College, which gradually developed into technical colleges to which a literary side was attached with provision for advanced humanistic studies. The oldest of these colleges was the Owens College, Manchester, which combined the curriculum of a university with that of a technical high school. Its school of applied chemistry was, for many years, one of the most flourishing in the country. In 1882 a somewhat similar school was founded in Liverpool as a university college, and the Yorkshire College of Science similarly widened its curriculum. To this college, a textile school, including a department for dyeing and design for textiles, was added by the munificence of the Clothworkers' Company of London. This department soon developed into one of the best-equipped institutions in the country for the study of the technology of textile manufacture. The three colleges at Manchester, Liverpool and Leeds were incorporated in the year 1885 into the federal Victoria University. Other textile schools for day students, providing a full course of advanced instruction, were founded at Bradford, Huddersfield, Halifax, Bolton, and in other parts of Yorkshire and Lancashire. In 1903 University College, Manchester, received a royal charter as the Victoria University of Manchester, and the University College of Liverpool became a separate university. In the following year the Yorkshire College received a charter of incorporation as the University of Leeds. These three universities provide full courses of instruction in engineering and in the industrial applications of science. Charters of incorporation as universities were also granted to the colleges at Birmingham and Sheffield. The Birmingham University, covering an area of over twenty-five acres, contains blocks of buildings devoted to the teaching of mining and engineering, and at Sheffield there is a special school dealing with the metallurgy of iron and steel.

The University of Manchester soon after its incorporation entered into arrangements with the municipal school of technology in that city, by which the faculty of technology was in part carried on in the well-equipped buildings of the municipal school, the largest institution of the kind in Great Britain. It was publicly opened in the year 1902. In these new universities ample provision is made for the teaching of electrical engineering and electro-technics generally, and the laboratories provided for this purpose are well equipped with machinery and apparatus, and compare not unfavourably with some of the most recently erected in Germany. Schools for mining engineers have been established at Wigan and Camborne and Redruth. In Wales, at different times, local colleges of university rank were opened in Cardiff, Bangor and Aberystwith, and those three colleges were subsequently united in the University of Wales. In all these local universities the technical instruction forms part of the ordinary university courses in which degrees are granted.

Other colleges outside London, besides those named, which participate in the government grant allocated to universities and colleges, giving higher grade instruction of a technical character, are University College, Bristol; Armstrong College, Newcastle-on-Tyne; and the university colleges at Nottingham, Reading and Southampton.

The University of Cambridge has a school of engineering with well-equipped laboratories for the teaching of pure and applied sciences. The universities of Edinburgh and Glasgow recognized at an early date, as part of a university course, the teaching of science in its application to engineering; and at University College, Dundee, there is a good school for the teaching of the technology of spinning and weaving, more particularly with reference to the manufacture of jute and linen.

The University of London.

In London, University College and King's College fulfilled for many years the function of a university and technical high school. Soon after the reorganization of the University of London in 1901, by which that institution was changed from an examining body into a teaching university, University College and King's College, which were named in the charter as schools of the university, transferred their funds, buildings, &c., to the university and became incorporated therein. The East London College, originally founded as a technical school in connexion with the People's Palace at Mile End, was admitted in 1907 as a school of the university, and under the statutes of the university certain teachers in the Polytechnic institutes became recognized teachers, and their students were admitted to graduation as internal students. Most of the students so admitted graduate in the faculty of engineering. For several years it was apparent that the work of the City Guilds Central College and that of the Royal College of Science and School of Mines overlapped to some extent, and that the teaching in each separate institution was incomplete and needed to be supplemented by that provided in the others. A departmental committee was accordingly appointed by the president of the Board of Education in the year 1904 to consider the working of the government College of Science and the School of Mines and their relation to other similar schools, and as a result of the report of that committee, published in 1906, a charter of incorporation was granted in 1907 to a new institution under the name of the Imperial College of Science and Technology, in which the teaching given in the three schools would be co-ordinated under a new governing body, consisting of members appointed by the Crown, the Board of Education, the City and Guilds of London Institute, the University of London and the principal engineering societies, with power to negotiate with the university for the transfer to the new institution of the engineering departments of University College and of King's College. The Exhibition Commissioners of 1851 agreed to grant unoccupied sites of land at South Kensington for the extension of, and the addition of new departments to, the existing colleges, and large annual endowments were promised by the government and the London County Council in addition to sums of money from private sources. The new Imperial College of Science and Technology is constituted by charter a school of the university, and is intended to provide the highest instruction in engineering and applied science, with facilities for advanced research work. The scheme was intended, when complete, to supply the metropolis with a technical school of the highest grade, similar to some extent to the well-known institutions in Berlin (Charlottenburg) and Massachusetts, but adapted to the special industrial needs of the British empire.

Legislative Enactments.—The state organization of technical education in the United Kingdom is mainly the result of enactments passed in and after the year 1890. Before that date, however, as early as 1877, the Livery Companies of London, with a view to fulfilling the purposes for which by charter they were originally incorporated, began to consider how best they could initiate a national scheme of technical education, for which, owing to the depression of trade and the changed conditions under which British industries were conducted, a strong demand had arisen. They consulted leading manufacturers and some of the best-known scientific authorities, and in 1880 an association was formed of the City corporation and some of the wealthier City companies under the name of the City and Guilds of London Institute for the advancement of technical education. The scheme of the institute was to establish a central institution at South Kensington, somewhat on the lines of the high schools of Germany, and one or more technical schools of intermediate grade in London, and to encourage by means of grants of money and by examinations for certificates technical classes and trade schools in different parts of the United Kingdom. In March 1880, an organizing director and secretary was appointed to develop and give effect to the scheme. As indicating the importance of the movement King Edward VII., then prince of Wales, accepted the office of president of the institute, which thus led the way to the establishment, under the direction of the government and under the control of local authorities, of a national system of technical education. The successive steps by which the system was evolved, and how it was gradually incorporated into the general scheme of education, are matters of interest in the history of education. A definition of "technical instruction" applicable to the varied teaching of the United Kingdom was, in the first instance, fixed by act of parliament. The term included instruction in science, art, and technology, and also in manual training; and by "technology" was understood the practical application of different kinds of knowledge to a particular trade, or industry, or employment.

State organization of technical education in United Kingdom.

Action of Livery Companies of London.

The National Association.

The progress of technical education was very much helped by the formation of the "National Association for the Promotion of Technical Education," which was inaugurated at a meeting held on the 1st of July 1887 and dissolved when its objects had been fulfilled, in June 1907, after twenty years of useful work. The general objects of the association were to promote and watch legislation, to spread information, and to discuss and assist in giving effect to the recommendations of royal commissions appointed to inquire into educational methods and organization. To its activity the development of technical education in England had been largely due. The first legislative effort to give effect to the recommendations of the Royal Commission on Technical Instruction, whose report was published in 1884, was a bill introduced into parliament in July 1887. The purpose of this bill was to enable school boards and local authorities to provide out of the rates technical schools, or to contribute to their support. A special provision of the bill was that a poll might be demanded by fifty ratepayers before any action could be taken under the powers it conferred. Technical instruction was so defined as to include subjects aided or sanctioned by the Science and Art Department. The bill was read a second time on 9th of August 1887, but never reached the committee stage. In the following March a new bill was introduced on behalf of the "National Association." It empowered school boards to provide technical instruction in schools under their management, and to contribute to the maintenance of higher technical institutes. The definition of technical instruction was widened so as to include the use of tools, commercial subjects, modern languages, and any subjects sanctioned jointly by the Education Department at Whitehall and the Science and Art Department at South Kensington, which at that time were practically separate government departments. The bill gave very extensive powers to school boards. It was withdrawn without a second reading, in view of the avowed intention of the government to deal with the subject. On the 17th of May 1888 the government bill was introduced. It contained several new features which pointed in the direction of subsequent legislation. Whilst school boards were again empowered to provide technical instruction in their own schools, they were also required, under certain conditions, to aid in the supply of technical and manual training in voluntary schools. At the same time the local control of secondary technical instruction was placed in the hands of a separate authority, viz., the "authority empowered to carry out the Public Libraries Acts." Additional rates, limited in each case to 1d. in the £, might be levied. The bill bristled with difficulties. It aimed at placing the voluntary schools, as regards technical instruction, under the control of school boards, but set up a new authority for the control of technical instruction higher than elementary. There was a growing belief, however, that school boards were not the most suitable bodies for the direction or control of technical education. This belief arose from the difficulty of devising means for securing equal advantages to both classes of elementary schools, and from the general unwillingness to extend school board authority beyond the limits of elementary instruction.

Bill of 1888.

No reference was made to technical education in the Queen's Speech in opening the parliamentary session of 1889, but the subject had been fully discussed during the recess. The difficulties in the way of legislation on the lines previously attempted were now clearly understood, and it was recognized that separate and distinct measures would have to be adopted for providing technical instruction in elementary schools and in schools of a higher grade. During the year 1889 three bills were introduced by private members. Two only of these bills were considered: the one dealing with elementary education, and enabling school boards to give technical teaching in schools under their management; the other enabling local authorities to establish or contribute to technical schools and classes. The former bill was fully discussed, but in the absence of any practical settlement of the voluntary school difficulty the government withdrew its support, and the bill was dropped. About this time the passing of another legislative measure helped very considerably towards the solution of the difficulty. The Local Government bill, which became law in 1888, enacted that "a council shall be established in every administrative county . . . and be entrusted with the management of the administrative and financial business of that county." A number of new representative bodies known as county councils were thus created, with powers similar in character to those possessed by the old boroughs. To these newly constituted bodies were transferred all business previously conducted by the quarter sessions. The act conferred similar powers on certain boroughs, according to their population, which were known as county boroughs. By utilizing these county municipal bodies for educational purposes the necessity of entrusting technical instruction to school boards was avoided; and accordingly, on the 24th of July 1889, the government introduced into the House of Commons a bill conferring upon county and county borough councils, and also upon urban sanitary authorities, the power to levy a rate not exceeding 1d. in the £ for the purpose of promoting technical and manual instruction in their district. This bill met with serious opposition from school board authorities and their friends, who resented the limitations it imposed on their educational aspirations; but the government was resolved to pass it, and after much obstruction it became law on the 19th of August 1889, having passed through all its stages in the House of Lords in a single sitting. The bill marked an epoch in the history of education, being the first legislative enactment dealing with technical instruction in England.

Local Government Act, 1888.

The act (Technical Instruction Act, 1889) provided that:

> The expression "technical instruction" shall mean instruction in the principles of science and art applicable to industries, and in the application of special branches of science and art to specific industries or employments. It shall not include teaching the practice of any trade or industry or employment, but, save as aforesaid, shall include instruction in the branches of science and art with respect to which grants are for the time being made by the Department of Science and Art, and any other form of instruction (including modern languages and commercial and agricultural subjects), which may for the time being be sanctioned by that department by a minute laid before parliament, and made on the representation of a local authority that such a form of instruction is required by the circumstances of its district.

Although at first received with no great favour, the act proved useful, and is important as representing the outcome of a number of abortive attempts at legislation, occupying three years, and intended to give practical effect to some of the recommendations of the Royal Commission of 1884. The act definitely settled the question as to the local authority for technical instruction, and decided it against the school board. It contained no provision, however, for the supply of technical instruction to children in either voluntary or board schools, and even expressly excluded from any share in its benefits all scholars receiving instruction in the obligatory or standard subjects. A way was soon found, however, of providing for technical instruction in elementary schools without any fresh act of parliament, and the difficulty of reconciling the interests of voluntary and board schools, which had impeded previous attempts at legislation, was thus avoided.

London School Board Joint Committee.

Early in 1886 the School Board for London, finding that it was unable to expend on technical instruction any part of the school board rate, applied to the City and Guilds of London Institute for financial help. The application was favourably received, and in the following year a joint-committee was formed, consisting of representatives of the Board, of the Institute and of the Drapers' Company. With the funds supplied by the Company and the Institute the committee were enabled to try some interesting educational experiments. Six centres for workshop instruction were equipped, and children were received into the classes from voluntary and board school. A scheme of instruction was prepared with the object of bringing into prominence the disciplinary character of the teaching, and of distinguishing it from the rule-of-thumb methods adopted in the workshop of commerce; and the experience of foreign schools, especially those in France, was utilized. The fears of trade unions lest the action of the school board would have the effect of increasing the number of trade carpenters were minimized, and the real value of manual training as a part of general education was for the first time illustrated. The experiment proved so successful that H.M. inspectors reported most favourably on the usefulness of the teaching, and on the value of the instruction in improving the general intelligence of the pupils, and particularly in rendering them more skilful and observant. Indeed, it was found that their progress in ordinary school studies was quickened by the practical training of the shop. As the result of these experiments the "use of tools" was recognized in the government code of 1890 as a subject of school instruction on which grants were to be paid, and towards the cost of which the school board rate was applicable. Later, following further experiments by the joint-committee, laundry-work and housewifery were included in the curriculum, and the problem of introducing so-called technical teaching into elementary schools was solved without any special legislation. Since 1890 manual training has formed a part of the elementary school system. The instruction includes the use of wood-working and metal-working tools, but stops short of teaching any particular trade, and is thus differentiated from the teaching given in the municipal schools of Paris. The new code also provided for a more rational system of object-lessons and of rudimentary science teaching, encouraging practical exercises and experiments to be worked by the pupils themselves. The joint-committee having completed its work, ceased to exist in 1900.

Local Taxation Act, 1890.

The act of 1889 and the code of 1890 enabled local authorities and school boards to provide out of the rates technical instruction for the working classes. The rate available under the act was limited to one penny in the pound, and very gradually, and with some hesitation, certain local authorities put the act in force. The motive power required for promoting technical instruction, other than that in elementary schools, was, however, still wanting, and might have remained so for some time longer if it had not been for the accident that in the following year, during the discussion in parliament of the question of compensation relating to public-houses, the residue of the beer and spirit duty was found to be unappropriated, and was allocated to county and county borough councils and made available for the purposes of technical education. The Local Taxation (Customs and Excise) Act, which became law on the 18th of August 1890, was "an act for the distribution and application of certain duties of customs and excise," and it provided that the residue of the English share of these duties should be distributed between county and county borough funds, and made applicable "for the purposes of technical education within the meaning of the Technical Instruction Act, 1889." By the express terms of this act this disposition of the residue, which then amounted to £743,000 for England and Wales, was revocable by parliament, and the allocation of the fund to education was left to the discretion of the local authorities. The grant accordingly was not generally regarded as permanent, and local authorities hesitated to commit themselves to any definite educational schemes. Indeed, it was seriously doubted whether such a windfall was likely to be made a permanent annual contribution from the state to the purposes of technical education. But gradually small sums were provisionally voted in aid of existing schools; and when the then Chancellor of the Exchequer declared that, if the "whisky" money (as it was commonly called) were found to be well and carefully expended, no future Chancellor would be able to divert it to any other purpose, local authorities began to consider how the money that had fallen into their hands might be best employed to meet local educational needs. Special committees were accordingly formed, consisting in many cases not only of members of the county or county borough council, but also of other persons versed in educational matters, to whom the preparation of schemes of instruction suitable to the several districts was referred. The committees so constituted, known as technical instruction committees, were established in different parts of the country, and to these bodies was delegated, subject to periodic reports to the council, the responsibility of dealing with the moneys at their disposal. The technical instruction committees proceeded in nearly all cases to elect as secretary a gentleman of scholarly attainments and educational experience, capable of advising as to the organization of schools and classes in accordance with the terms of the act and the special requirements of the district. As a result of the acts of 1889 and 1890 local educational authorities altogether distinct from school boards came into existence, each with an organizing secretary acting as educational officer for the district. The creation of these educational authorities, with functions, however, limited to technical instruction, marks the most important step in the organization of education since the establishment of school boards.

Technical instruction committees.

By special minutes of the Science and Art Department new subjects were from time to time included under the term "technical," and the definition of technical education was gradually widened. Among the subjects first added to the list were those included in the "programme of technological examinations" of the City and Guilds of London Institute, and the teaching of technology, as distinct from science, was thus for the first time officially recognized and aided by grants from public funds. Later, commercial subjects and modern languages, the theory and practice of agriculture, and the arts and crafts underlying various cottage industries were accepted as branches of technical instruction; and whilst, on the one hand, the definition was so widened as to include nearly all that is comprised in the curriculum of a secondary school, the teaching of certain technological subjects approached so near to trade teaching that the provision excluding "the practice of any trade or industry or employment" from the teaching sanctioned by the act appeared likely to be overlooked. Practical instruction in engineering, weaving, printing, photography, plumbing, carpentry, brickwork, bookbinding and other subjects was encouraged by the City and Guilds Institute, acting as a central authority for education of a distinctly technological character; but notwithstanding the continued increase in the number of practical classes in different branches of technology, the teaching of technology as distinct from that of science and art received at this time no direct support by means of grants in aid from the state. Under the new conditions, however, of assessing the government grant, introduced into the Directory of 1901–02, instruction in technology received some form of recognition.

Curriculum.

The county of London remained for some time behind other counties in utilizing the provisions to the Technical Instruction Act of 1889, by devoting to educational purposes the funds placed at its disposal by the Local Taxation (Customs and Excise) Act, 1890. The funds applicable to London, which in the first instance amounted to about £163,000, but soon reached a total of about £200,000, were wholly employed for a period of two years in relief of the rates. The wants of London were not at first understood; and it was thought that sufficient funds for educational purposes might be obtained from other sources. A scheme for the utilization of a fairly large income arising from the City parochial charities had been under the consideration of the Charity Commissioners. It was first published in 1888, and, after some discussion and modification, was sanctioned by parliament. According to that scheme a capital sum of about £150,000, supplemented by a like amount obtained from the City companies and other sources, was made available for the building of technical and recreative institutions for the poorer classes of the working population of London, similar to the Polytechnic in Regent Street and the People's Palace in Mile End Road. The scheme created a central governing body for the general supervision of these institutions, and placed at its disposal an income of about £50,000 available for educational purposes, which, with the falling-in of leases, was certain to increase. Provision for the endowment of eight polytechnics and of other educational institutions was made in the scheme, and the Goldsmiths' Company undertook to erect and maintain from its corporate funds a ninth, which has since been presented by the Company to the University of London, and under the name of the Goldsmiths' College is used mainly as a school for the training of teachers. Since then other similar but somewhat smaller institutions have been established.

Schemes for London.

Before the erection of these new institutions was completed it was ascertained that the annual income at the disposal of the trustees for the purposes of maintenance and equipment was altogether inadequate; and a committee of inquiry having been appointed by the London County Council, an exhaustive report on the educational needs of the metropolis was prepared, which led to the formation of a Technical Education Board for London, consisting of members of the County Council, who formed the majority of the board, and also of representatives of the City Parochial Trustees, of the City and Guilds Institute, of the School Board, and of other bodies; and to the board so constituted the council entrusted the spending of the funds available under the Local Taxation Act, 1890. The board held its first meeting on the 28th of April 1893, but ceased to have a separate existence in 1903 on the passing of the London Education Bill. During those eleven years the board, with the assistance of its organizing secretary, succeeded in arranging a comprehensive and varied scheme of scholarships, which, among other benefits, enabled children from the elementary schools to continue their education in intermediate schools, and to pass on to the higher technical institutes and universities. It supplemented by large grants the income of the polytechnic institutions; it established or assisted in establishing new trade schools; it provided laboratories, and aided in the teaching of practical science in a large number of secondary schools; it encouraged the teaching of modern languages and commercial subjects; it assisted in founding a school of economics, which has become a constituent part of the new University of London, and utilized in nearly all instances with the best possible results the large annual income allocated by the County Council to technical education.

Work of the Technical Education Board, London.

The close connexion between technical and secondary education was clearly indicated in the comprehensive definition of the former term given in the act. But it soon became manifest that no great progress could be made in technical education unless further provision were made for secondary education and unless some improvement could be effected in the methods adopted in secondary schools. The cry of Matthew Arnold for the better organization of secondary education had, so far, met with no adequate response. There was still an insufficient supply of secondary schools, and a complete absence of advice or control by any central authority. The urgency of this need was recognized by the "National Association for the Promotion of Technical Education," which at a meeting held in July 1889 resolved to alter its title by the addition of the words "and Secondary" after "Technical." This verbal alteration represented a widespread conviction that technical and secondary education are of necessity closely associated, and that future efforts should be directed towards the improvement and organization of secondary education and the union of different grades and branches of education under a single government department. That the Technical

Connexion with secondary education.

Instruction Act would need to be followed by a Secondary Education Act was generally recognized. Accordingly, after much discussion, the government in the year 1896 introduced into parliament a comprehensive measure dealing with education as a whole and embodying the principal recommendation of the Royal Commission on Secondary Education. The bill was well received, and, if the government had persevered with it, would have passed into law, and the question would have been settled for a generation. It was wrecked owing to the difficulty of satisfying the aspirations of the smaller boroughs to be constituted as local education authorities. No further action was taken till 1898, when a new bill was introduced by the government, creating a Board of Education, and combining under one department the functions of the Education Department at Whitehall and of the Science and Art Department at South Kensington, with certain powers relating to the educational work of the Charity Commissioners. The bill was fully discussed during the recess, and in a slightly altered form it became law in the early part of the year 1899, and came into operation in April 1900. The Board of Education called into existence by the act thus became the central authority for elementary, secondary and technological instruction. Provision was made in the act for the creation of a consultative committee of educational experts to be appointed by the president, whose special duty was to prepare and keep a register of all qualified teachers. As then constituted, the board consisted of the secretary, responsible to the president for the administration of both primary and secondary education, of two principal assistant secretaries, and of subordinate officers. An assistant secretary for secondary and another for technological instruction were appointed, both under the direction of the principal assistant secretary at the South Kensington branch. With a view to co-ordinating the technological instruction to be carried on by the board with that undertaken by the City and Guilds of London Institute and other bodies, a departmental committee was appointed in November 1900 on which those bodies were represented. As a result of the recommendations of that committee arrangements were made for co-ordinating to some extent the work of the City and Guilds Institute with that of the Board of Education. In the regulations issued in 1902 for assessing the amount of state aid to be given by way of grants to technical schools it was provided that the whole instruction given in any school, in technology as well as in science and art, should be considered; formal recognition was given to the certificates issued by the Institute, and the Examination Board of the Technological Department of the Institute was strengthened by the addition of four members nominated by the Board of Education. The teaching of science and art, as applied to specific trades and industries, was thus brought under the direct supervision of the central educational authority.

Creation of Board of Education.

It was, however, the Education Act of 1902 which freed technical education from the restriction which had prevented its natural development. For some time the opinion had been gaining strength that all grades of education should be controlled by the same local authorities. The distinction between elementary and secondary education had been bridged over by various types of higher grade schools, and the difficulty of assigning to school boards the control of elementary schools, and to municipal bodies, also popularly elected, the control of education other than elementary, was found to be almost insuperable. A comprehensive measure of reform was regarded as indispensable. This necessity was emphasized by the fact that the managers of many voluntary schools, notwithstanding the state aid which they received as government grants, found the strain almost intolerable of meeting the ever-increasing requirements of the government as regards elementary education by means of private subscriptions. The new Education Act transferred to the local authorities, acting through education committees to be constituted by schemes to be approved by the authorities at Whitehall, the functions and duties of school boards, the separate existence of which, after a life of thirty-two years, was thus terminated. The same act threw upon the rates the burden of contributing to the support of voluntary schools, which, under certain conditions of management, were placed, as regards secular instruction, entirely under the control of the local authorities. School education of all grades was thus brought under the control of the same bodies, both as regards central and local administration, and the government and local authorities were free, under certain limitations imposed by the act, to prepare schemes for elementary, secondary and technical instruction, and for the award of scholarships enabling children to proceed from the elementary schools to the universities. By this act a national and unified system of education was effected for England and Wales.

Unification of education under Act of 1902.

In accordance with the act, which did not apply to London, municipal bodies were expected to appoint education committees from among their members and to co-opt a certain number of persons, including some women, versed in educational matters or representing educational interest. The London County Council, which had not regarded with favour the abolition of the school boards, showed no disposition to accept the aid of persons from outside who were not directly elected to represent the ratepayers, and although in 1903 an act was passed for the direction of education in London, the Board of Education reluctantly assented to a scheme prepared by the London County Council which vested the control of education in the hands of a committee consisting exclusively of members of the council with the addition of some women. At the municipal elections of 1907 the Progressives, who had hitherto formed the majority of the council, were defeated, and the Municipal Reformers reversed in this respect the policy of the previous council.

The London Act of 1903;

The Act of 1902 was strongly opposed by Nonconformists and by the Liberal party generally, and at the general election of 1906 a parliament was returned pledged to effect such changes in it as would give to the local authorities a more direct control over voluntary schools. Accordingly, one of the first measures introduced was a new Education Bill, which, after a protracted discussion, was passed by the House of Commons and amended in several particulars by the Upper Chamber. The amendments of the Lords were rejected *en bloc* and the bill was withdrawn. In the following year some of the less contentious clauses were embodied in the Education (Administrative Provisions) Bill, which received the royal assent, and among its clauses was one which widened the definition of education, so as to include any kind of training which might be pronounced by the board to be educational in character. By an administrative act of the board, a new department under a separate secretary, but responsible to the Minister of Education, was created for Wales, which thus, without any act of parliament, practically acquired independent control of its educational machinery.

The Bill of 1906.

The Act of 1907.

The foregoing statements refer more particularly to England and Wales, to which prior to 1907 all acts of parliament dealing with education subjects were generally applicable. In Scotland and in Ireland the organization of technical instruction proceeded on different lines. A Technical Schools Act, applicable to Scotland only, was passed in 1887. This act enabled school boards by means of the school funds to provide and maintain technical schools. The act has proved to be practically inoperative. In Scotland, however, school boards have been entrusted with much larger powers, and possess greater influence, than in England. Many of the secondary schools of Scotland are under the direction and control of school board authorities. The residue of the beer and spirit duties under the Local Taxation Act applicable to Scotland was much less, even relatively to the population, than in England, and was, moreover, divided directly among so many different authorities as to be in most cases of little or no real value for educational purposes. Recently attempts have been made to combine the funds distributed among different neighbouring authorities, so as to bring them under the control of a single body for the benefit of a larger area. In the year 1896–97 the Education Department of Scotland was entirely separated from that of England, and there was a consequent transfer of functions and grants from the latter to the former. By the passing of the Local Taxation (Scotland) Act, 1898, the residue grant was relieved of certain charges, and additional funds thus became available for technical education. No grants for science or art instruction are made to Scottish schools from the English Board of Education; but several of the technical schools avail themselves of the examinations of the board, and also of those of the City and Guilds of London Institute. Among the equipped technical colleges in Scotland may be mentioned the Heriot-Watt College of Edinburgh, the Glasgow and West of Scotland Technical College, Glasgow, the Robert Gordon College, Aberdeen, and the Technical College, Dundee. These do not differ in any essential points from corresponding schools in England. The system of instruction is very similar, and among the subjects taught will be found most of those included in the Regulations of the Board of Education and in the programme of the City and Guilds of London Institute. Special attention is given in some of these schools to the teaching of the principles and practice of the different branches of textile manufacture. Manual training forms an important part of the curriculum of primary and secondary schools, and the instructions to inspectors on science teaching issued by the Scottish Education Department show a just recognition by the department of the proper methods to be adopted in the teaching of science as a part of general education. Under the Scottish system leaving certificates are awarded on the results of examinations held at the close of the ordinary school course. These examinations cause the minimum of interference with the ordinary school work. At the universities of Edinburgh, Glasgow and Aberdeen the higher technical instruction in such subjects as engineering and naval architecture is well developed.

Scotland.

Ireland remained behind Great Britain as regards facilities for technical education. Although the Technical Instruction Act (1889) applied to Ireland as well as to England and Wales, very little use was at first made of its provisions. Moreover, the Irish share of the funds available under the Local Taxation Act is definitely allocated to intermediate education. A committee known as the Recess Committee published in 1896 some valuable and important recommendations, which led to the passing of the Agriculture and Technical Instruction (Ireland) Act of 1899. The reports of two commissions, one on manual and practical instruction in primary schools, and the other on intermediate education, contained suggestions which gave encouragement to the practical

Ireland.

teaching of technology and helped to promote a better system of instruction in Irish schools.

The work was successfully commenced under the direction of the newly constituted Department of Agriculture and Technical Instruction, consisting of an Agricultural Board, a Board of Technical Instruction, a Council of Agriculture, and a Consultative Committee of Education. The department had an endowment of £166,000 a year, which was distributed among the several branches. It took over the duties of several other administrative bodies, and the grant for science and art for Ireland, and the grant in aid of technical instruction in Ireland as defined by the Technical Instruction Act of 1889, previously administered from South Kensington, was transferred to the new department. Among the industries for which the department is now occupied in organizing courses of instruction are engineering, textiles (particularly linen manufacture), shipbuilding, agriculture and the fisheries. The operations of the department extend to all grades of schools, from the Royal College of Science, Dublin, organized as a Central Technical College, to the elementary and secondary schools which the department enters for the administration of the science and art grants to the evening technical classes conducted by local authorities. The first annual report of the department, published November 1901, showed that successful efforts had been made to improve science teaching as a part of general education, and to develop on correct lines manual training and technological instruction. The municipal school of technology at Belfast, opened in 1907, is an institution similar in many respects to those of Manchester and Birmingham, and providing technical instruction in connexion with a great variety of industries. There is also a large school at Dublin, and schools have been established in Cork, Limerick and elsewhere.

Results of Experience.—Experience has helped to establish certain principles as applicable to technical education. It is now generally admitted that whilst the age at which the ordinary school training should cease, and technical or professional education should commence, must vary for different classes of workers, the teaching special to any industry or employment should supplement, and not form part of, general education. The subjects entering into the school curriculum may be, and in certain cases should be, selected with reference to their applicability to certain callings, but they should be so taught as to become instrumental in the formation of mental habits and the development of character, the mere knowledge or skill acquired being of secondary importance. In the teaching of science there has been a marked change in method. Formerly the usefulness of the knowledge to be derived from the study of nature gave to physical science its chief claim to a place in the school curriculum, but it is now held that the real value of the study consists in the opportunities it affords of exercising the pupil in accurate observation, and of developing resourcefulness and powers of independent thought and reasoning. Whilst the opinion in favour of postponing as long as circumstances permit all specialized instruction has become of late years more pronounced, there has been a growing tendency, not only in England but also on the Continent and in the United States, to associate technical teaching more closely with workshop practice. The professional or trade teaching, which is supplementary to primary or secondary education, is more practical and less easily distinguishable by the ordinary observer from the training of the factory or workshop. This tendency is shown in all grades of technical education. The technical institutes established in London and in the large English manufacturing towns, attended mainly by evening students, are provided not only with expensive laboratory apparatus for the teaching of applied science, but also with tools and machines for the teaching of technology; and some of the departments of these schools are equipped so as to resemble a small factory. This is the case in the departments devoted to the teaching of mechanical and electrical engineering, weaving, and spinning, watch- and clock-making, boot and shoe manufacture, and the different branches of the building and printing trades.

Changes in the conception of what technical education should be.

So far, however, no attempt has been made, except in very special cases, to teach the practice of any special trade. The teaching of technology is distinct from trade teaching. In all the technical institutes of London, and in most of those of other towns, none but persons actually engaged in the industry, the technology of which they are desirous of studying, are admitted to the workshop classes. The instruction given in such classes is very different as regards method, and also in its aims and objects, from the training of apprentices in the factory or trade shop. The tools and appliances are the same, but they are used rather as a help to the teachers in illustrating principles than as a means of enabling the student to acquire that dexterity and skill which constant practice can alone secure. With the general cessation of apprenticeship, as formerly understood, it is only in the school workshop that the young artisan has any opportunity of learning the use, and the principles underlying the use, of the instruments and appliances connected with his trade; and in those industries in which automatic machinery is gradually displacing hand labour he is altogether dependent upon school teaching for any knowledge he may wish to acquire of the processes involved in the particular manufacture, in some small section of which he is exclusively engaged. Modern technological teaching is essentially practical, but it is nevertheless different in kind from the mechanical and sectional practice of the factory of commerce; and except in some few, mainly artistic, crafts, there is no entrance to a trade through the door of the school workshop. In other countries, particularly in France, the case is different. The school, in many branches of industry, is accepted as a substitute for the shop, and the lad is so trained that he acquires in the school not only a knowledge of the principles of the trade, but sufficient dexterity and skill to enable him, on leaving school, to take his place among wage-earning operatives. It is only in day schools, in which the pupils spend the greater part of their time in workshop exercises, that trade teaching can be so developed. There are schools in England in which manual training in wood and metal work is carried beyond the limits of mere educational discipline; but even in those schools no special trades are taught, and the experience of recent years has only tended to emphasize the principle, that the education given in the ordinary day schools, whether primary or secondary, should be formative and general, rather than technical or professional.

Relations with practical trade.

Owing partly to climatic conditions, and partly to the fact that the hours of labour are somewhat shorter in England than abroad, evening schools of technology are likely to occupy a permanent place in the English system of technical education. In these schools all grades of workmen will continue to receive their special supplementary instruction; and it is from among the workmen so trained that foremen and works managers will generally be selected. Some intermediate teaching, however, is necessary between that of the elementary school and the technical class as a preparation for technological instruction. A knowledge of workshop arithmetic and geometrical drawing is indispensable, and it is in the evening continuation classes that such knowledge may be best acquired. These classes supply the teaching which may be regarded as the connecting link between elementary and technological instruction, and attendance at such classes will gradually become a necessary condition of entry to a technological course.

By means of scholarships a large number of children from the elementary schools are now enabled to continue and complete their general education in day schools of a higher grade. Nearly every county has its scheme of scholarships, providing facilities for the further education of children who show special abilities and aptitudes. These scholarships are awarded under conditions which differ very widely in different localities. Pupils from the higher-grade schools enter industrial life at a later age than those from the elementary schools, and, by reason of the more advanced instruction they have received, are at once qualified to enter classes in technology. In these schools practical teaching is further developed, both in the laboratory and workshop, but as a part only of the ordinary school course; and it would be incorrect to describe such schools as *technical* in the strict sense of the term. The position of these higher-grade schools in the general educational scheme was the subject of an important action (*Rex* v. *Cockerton*, 1901) in which it was decided by the law courts that the school boards were unable to apply the rates to the support of such schools. They were accordingly withdrawn from the sphere of elementary education, and have since been treated as schools of a secondary type. The judgment on appeal was conclusive, that the school board rates could be employed only for the provision of elementary education for children, whether in the day or evening, and this decision paved the way for the dissolution of school boards, and to the transfer of their duties and functions to the county and borough councils under the Act of 1902.

Types of secondary schools. As regards secondary schools proper, in their relation to technical education, it is important that the curriculum of such schools should be sufficiently varied to afford a sound liberal and preparatory training for the different branches of professional work. It is generally admitted that at least three types or departments of schools are needed—(*a*) the classical, (*b*) the mathematical, and (*c*) the modern language type; and that each of these divisions should contain sub-departments. The first of these varieties would be available for the general training of students wishing to enter the legal, theological or literary professions; the second for those preparing for engineering, manufacturing or agricultural pursuits; and the third would be found best fitted as a preparation for a commercial calling. These schools would correspond to some extent to the three kinds of secondary schools found in Germany, and would be available for students preparing to enter one or other of the faculties of a modern university. The organization of different types of secondary schools, and the curriculum appropriate to each, are matters which continue to occupy the attention of educational experts. In accordance with the regulations for secondary schools issued by the Board of Education in 1907, substantial grants were made to secondary schools which conformed to certain conditions as regards local control and undenominational religious instruction, or the directive influence of the board as regards curriculum and management over all such schools was strengthened. At the same time, manual training and domestic science were made essential parts of the curriculum in boys' and girls' schools respectively.

The demand for technical education, which originally led to the formation of the City and Guilds of London Institute, directed attention to the methods of teaching science, drawing and other subjects, and to the necessity of including science in the curriculum of all grades of schools. The methods of science teaching have been greatly improved. Experimental work has become essential, and methods of investigation and research have been applied to the teaching of a number of subjects to which formerly they would have seemed inapplicable. A close connexion has thus been established between the workshop and the classroom, and practical instruction is now regarded as a necessary part of general education both elementary and secondary, and as no less disciplinary than the merely literary and oral teaching it has partly superseded. This change in the school curriculum and in the methods of instruction has narrowed the true significance of the term "technical" as applied to education. By the term "technical" as commonly used is now understood "technological" or "professional," and whilst technological instruction may supplement either primary or secondary education, it is necessarily distinct from either.

The conviction has been steadily gaining ground that success in manufacturing industry, in the higher walks of commerce, and in every pursuit requiring technical knowledge, depends very largely upon the thorough and complete training of those who are charged with the control of the different kinds of work in which the army of operatives are engaged. Intelligent and highly skilled workers are indispensable; but unless they are properly directed by efficient and expert officers they can effect but little. *German example.* It is undoubtedly due to the careful training of the masters and leaders of industry that the Germans have achieved so large a measure of success in different technical pursuits. The recognition of this fact is slowly but surely influencing educational thought and action in Great Britain; but Germany is still ahead in the facilities afforded for higher education, and in the advantage taken of the facilities that exist. The number of students in her universities and technical high schools is still in excess of those receiving a similar training in Great Britain. The establishment, however, of local universities and the schemes for the award of scholarships adopted by local education authorities, will tend year by year to lessen this disparity. Meanwhile, Germany has relaxed none of her former efforts, but is steadily occupied in the enlargement and improvement of her educational institutions. New schools have been erected, wherever and for whatever purpose they are needed, equipped with every modern appliance for scientific investigation and research. Each professional career has its corresponding high school or university department. The economy of a wise and liberal expenditure on higher education is a recognized fact in German statecraft.

For those who are intended to occupy the highest posts in industrial life, a sound secondary education, supplemented by appropriate university training, is the best preparation. It is only in the university or tertiary grade of education that specialized or technological training for the higher industrial posts should commence. At this stage of education, general and professional teaching are more closely associated, and the names of the faculties of the new universities in the United Kingdom will in future indicate the several branches of professional work to which the different courses of university study are intended to lead. Of late there has been a marked development of distinctly technical instruction in connexion with the colleges of university rank. The error of restricting university studies to a certain limited range of subjects, which led in Germany to the establishment of technical high schools as institutions distinct from the universities, has been avoided. Engineering, in the broadest sense of the term, has been recognized as a branch of university education of the same order as medicine or law. Laboratories and workshops have for many years formed part of the equipment of the principal university colleges. In the statutes of the university of London a separate faculty is assigned to engineering, and part of the work of the polytechnic institutes is correlated with that of the reconstituted university. A survey of the field of education shows that whilst the difference between technical and general education is well marked in the primary and secondary stages, it is the function of the university to liberalize professional teaching, and to afford opportunities for specialized study and research in the higher branches of knowledge applicable to the practical work of industrial life.

(P. M.*)

TECK, a ducal castle in the kingdom of Württemberg, immediately to the N. of the Swabian Jura and S. of the town of Kirchheim, crowning a ridge (2544 ft.) of the same name. It was destroyed in the Peasants' War (1525).

The duchy of Teck was acquired early in the 11th century by Berthold, count of Zähringen, whose great-grandson Albert, or Adalbert, styled himself duke of Teck. In 1381 it passed both by conquest and purchase to Württemberg. The title, which had lapsed with the extinction of the Zähringen line in 1439, was revived in 1495 by the German King Maximilian I., who bestowed it upon the dukes of Württemberg. The dignity was renounced by Duke Frederick William Charles upon his elevation to the rank of king in 1806. In 1863 the title "prince of Teck" was conferred by King William I. of Württemberg upon the children of Duke Alexander of Württemberg

(1804–1885) by his morganatic marriage with Claudine, countess Rhédey, ennobled as countess of Hohenstein; in 1871 Prince Francis, the eldest son of Duke Alexander, was created duke of Teck. His eldest son Adolphus (b. 1868) was in 1910 the holder of the title.

TECUCI (*Tecuciu*), the capital of the Tecuci department of Rumania, picturesquely situated among wooded hills, on the right bank of the river Bêrlad, and at the junction of railways from Bacau, Bêrlad and Galatz. Pop. (1900) 13,401. Tecuci has a large transit trade in grain, timber, cattle and horses, on their way from northern and eastern Moldavia to the Danubian ports. The neighbourhood of Tecuci was the scene of a fierce battle in 1476 between Stephen the Great and the Turks.

TECUMSEH, TECUMTHE, or TECUMTHA[1] (*c.* 1768–1813), American Shawnee chief, was probably born in the old Shawnee village of Piqua, near the site of Springfield, Ohio, between 1768 and 1780. While still a youth he took part in attacks on settlers passing down the Ohio and in widely extended hunting expeditions or predatory forays to the west and south; and he served in the Indian wars preceding the Treaty of Greenville in 1795. About 1800 his eloquence and his self-control made him a leader in conferences between the Indians and whites. After 1805 the Indians of the North-West became aroused by a series of treaties calling for new cessions of their territory and by the prospect of war between Great Britain and the United States. This presented to Tecumseh and to his brother Tenskwatawa (*i.e.* the Open Door), popularly called "the Prophet," the opportunity to put into operation a scheme which followed the ambitious dream of Pontiac. With some scattered Shawnee clans as a nucleus, the brothers proceeded to organize, first near Greenville, Ohio, and later on the White and Tippecanoe rivers in Indiana, "the Prophet's town," which was based on a sort of communism and was apparently devoted to peace, industry and sobriety, but their actual plan was to combine all of the Indians from Canada to Florida in a great democratic confederacy to resist the encroachment of the whites. Tribal organizations were to be disregarded, but all warriors were to be represented at periodical assemblages where matters of interest to all Indians were to be definitely decided. The twofold influence that was to dominate this league was the eloquence and political ingenuity of Tecumseh and the superstitious reverence aroused by "the Prophet." This programme alarmed the whites along the north-western border. In the course of the next three years Governor William Henry Harrison of Indiana held interviews with each of the brothers, and during one of these, at Vincennes in 1810, the respective leaders narrowly avoided a hostile encounter. Nevertheless "the Prophet" and Tecumseh reiterated their determination to remain at peace with the United States if the Indians were unmolested in their territory, and if all cessions beyond the Ohio were given up by the whites. The treaty of Fort Wayne in 1809, which called for the cession to the whites of some three million acres of land in central Indiana, was a direct challenge to this programme, and when, during Tecumseh's absence in the South, Harrison made a hostile move against "the Prophet's" town, the latter ventured to meet him, but was defeated on the 17th of November 1811 in the famous battle of Tippecanoe, which broke the personal influence of "the Prophet" and largely destroyed the confederacy built up by Tecumseh. Tecumseh still professed to be friendly toward the United States, probably because his British advisers were not ready to open hostilities, but a series of border outrages indicated that the fatal moment could not long be postponed. When, in June 1812, war broke out Tecumseh joined the British, was commissioned a brigadier-general in the British army, and participated in the skirmishes which preceded General William Hull's surrender at Detroit. He took an active part in the sieges of Fort Meigs, where he displayed his usual clemency toward his prisoners. After the battle of Put-in-Bay, when Colonel Henry Proctor began to retreat from Malden, Tecumseh bitterly reproached him for his cowardice and finally forced him to join battle with Harrison on the Thames river on the 5th of October 1813. In this battle Tecumseh was killed, as traditionally reported, by Colonel Richard M. Johnson of Kentucky, although this has never been fully substantiated. Like Pontiac, whom he doubtless imitated consciously, he had a wonderful eloquence and a power of organization rare among the Indians. His brother, "the Prophet," remained with a small band of Shawnees and died west of the Mississippi in 1834.

See Benjamin Drake, *The Life of Tecumseh and of his Brother the Prophet* (Cincinnati, 1841); and Homer J Webster, *Harrison's Administration of Indiana Territory* (Indianapolis, 1907).

[1] The name is said to mean "meteor," or "flying panther."

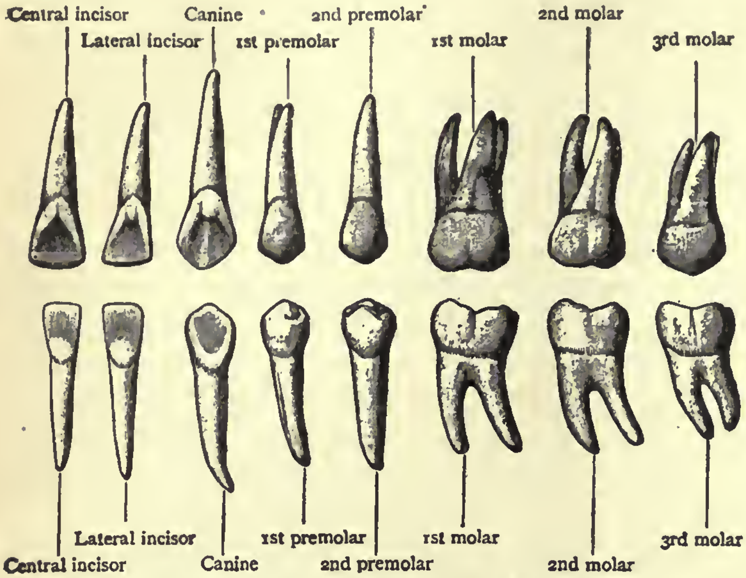
TEDDINGTON, an urban district in the Uxbridge parliamentary division of Middlesex, England, close to the Thames, 13 m. W.S.W. of St Paul's Cathedral, London, on the London and South-Western railway. Pop. (1901) 14,037. The district is residential and the town is a resort of visitors both to the river and to Bushey Park, which lies immediately south (see HAMPTON). The National Physical Laboratory, for making scientific investigations of industrial importance, and for mechanical testing, was opened in Bushey House in 1902.

TEES, a river of England, rising on the eastward slope of Cross Fell in the Pennine Chain, and traversing a valley about 85 m. in length to the North Sea. In the earliest part of its course it forms the boundary between the counties of Westmorland and Durham. The head of the valley, of which the upper portion is known as Teesdale, is not without desolate grandeur, the hills, exceeding 2500 ft. in height at some points, consisting of bleak moorland. A succession of falls or rapids, where the river traverses a hard series of black basaltic rocks, is known as Caldron Snout; and from a point immediately below this to its mouth the Tees forms the boundary between Durham and Yorkshire almost without a break. The dale becomes bolder below Caldron Snout, and trees appear, contrasting with the broken rocks where the water dashes over High Force, one of the finest falls in England. The scenery becomes gentler but more picturesque as the river descends past Middleton-in-Teesdale (Durham), the terminus of a branch of the North-Eastern railway from Darlington. In this locality lead and ironstone are worked. The ancient town of Barnard Castle, Eggleston Abbey, and Rokeby Hall, well known through Sir Walter Scott's poem, are passed; and then the valley begins to open out, and the river traverses in sweeping curves the rich plain east and south of Darlington. The course of the valley hitherto has been generally E.S.E., but it now turns N.E. and, nearing the sea, becomes an important commercial waterway, having on its banks the ports of Stockton-on-Tees, Thornaby-on-Tees and Middlesbrough, and forming an outlet for the rich ironworking district of Cleveland in the North Riding of Yorkshire. It is also navigable for barges up to High Worsall, 11 m. above Stockton. For the last five miles the course, below Middlesbrough, is estuarine. The drainage area is 708 sq. m. No important tributary is received.

TEETH (O.E. *teþ*; plural of tooth, O.E. *toþ*), the modified papillae or elevations of the mucous membrane of the mouth, impregnated with lime salts. Each tooth has a biting part or crown covered by enamel, a neck where the gum surrounds it, and one or more roots or fangs fitting into sockets (alveoli) in the jaw bone. For surgery of the teeth see DENTISTRY.

There are thirty-two permanent teeth in man, sixteen in the upper and sixteen in the lower jaw; they are also arranged in symmetrical sets of eight teeth on each side. The two teeth on each side of the mid-line in front are "incisors" and have chisel-shaped crowns. The mesial or central incisor of the upper jaw is broader than any of the others, consequently it bites against the central and lateral incisors of the lower jaw, and the same want of exact adaptation continues throughout the series, so that every tooth in the upper jaw except the last molar bites against its corresponding tooth of the lower jaw and the tooth behind that.

Next to the incisors comes the "canine tooth," the crown of which is somewhat peg-shaped, while behind this are the two "premolars" or "bicuspids," whose crowns are flattened from before backward and bear two cusps, the larger of which



From Ambrose Birmingham, in Cunningham's *Text-Book of Anatomy.*

Fig. 1.—The Permanent Teeth of the Right Side, Inner or Lingual Aspect.

The upper row shows the upper teeth, the lower row the lower teeth. The cingulum is distinct on the upper incisors and both canines, the lingual cusp on the upper lateral incisor and the upper canine.

is the external or labial cusp, while the smaller is the internal or lingual. As a rule there is a single root, though sometimes in the first upper premolar it is double.

The three "molars" are placed behind the premolars, and the upper and lower sets can be easily distinguished because the upper have three roots while the lower have only two. Of the three roots which the upper molars bear two are lateral or external and one mesial (see fig. 1), so that it is easy to tell the outer from the inner side of an upper molar. The front can, as a rule, be identified by the fact that the roots are generally bent a little backward at their tips, and this applies to other teeth than the upper molars. In the lower jaw, owing to the two fangs being anteroposterior, it is not possible to tell the lateral from the mesial surface of the molars by them, although the backward inclination of their tips shows the front from the back. When it is remembered that the upper teeth overlap the lower externally it is reasonable to expect that the lower molars would show some rounding due to wearing away of the edge of the crown on the outer side, and this is the case. The grinding surface of the crowns of the upper molars shows three or four cusps, while on that of the lower four or five are found.

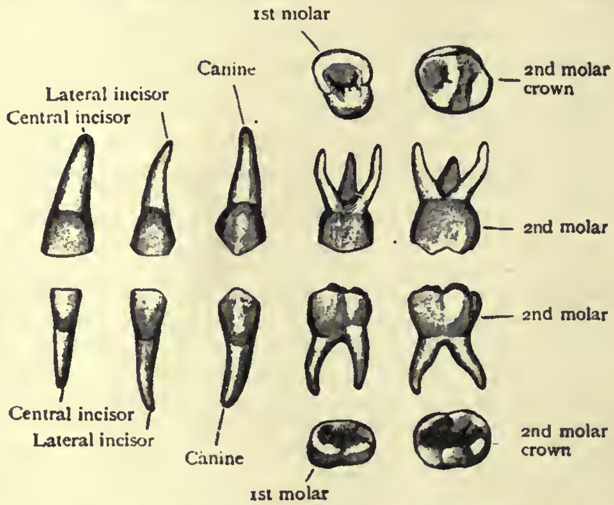
Of the three molars the first is the largest, and the third, or wisdom tooth, the smallest, while the upper wisdom tooth is smaller than the lower.

In the "milk teeth" or temporary dentition of the child there are only twenty teeth, ten in each jaw and five in each segment. They are two incisors, one canine, and two so-called molars. These molars occupy the position which the permanent premolars later on take, and it is held by many that the adult molars really belong to the milk dentition, although they cannot appear until the jaw has grown backward sufficiently far to make room for them. The temporary teeth differ from the permanent in their smaller size, their whiter colour, the greater constriction of their necks, and in the fact that the roots of the molars are widely splayed.

The dates at which the milk teeth are cut are very variable. The lower central incisors come first between the sixth and ninth month, or even later; then, after a few months, come the central and lateral upper incisors; again a few months' rest and the lower lateral incisors appear, followed closely by the first molars. After another rest of four or five months come the canines, the eruption of which is a slow process, while by about the end of the second year the second molars have appeared, and the milk dentition is complete. It will be seen from the above that the milk teeth are cut in batches with resting intervals between.

As C. S. Tomes points out, we do not know what causes the eruption of the teeth; the growth of the roots is not of itself enough to account for it. It is possible, however, that blood-pressure may be the determining cause. The first permanent tooth to be cut is the first molar, and this happens during or soon after the sixth year. It does not displace any of the milk teeth, but comes down behind the second milk molar. During the seventh year the central milk incisors fall out and their place is taken by the permanent ones; the shed teeth are mere shells of the crown, all the root having been absorbed, though not, as might be thought, owing to direct pressure of the succeeding tooth.

The lateral incisors succeed their milk predecessors at about eight years old, the first premolar takes the place of the first temporary molar about nine, the second premolar that of the second temporary molar about ten, the canine about eleven, while the second molar comes down behind the first about twelve, and so is known as the "twelve-year-old tooth." The third molar, or wisdom tooth, usually appears between eighteen and twenty, but may be much later, indeed it is sometimes never cut at all, and when it is, it often does not come down to a level with the other teeth. It is believed that man is gradually undergoing a suppression of his last molar teeth, which, if the process continue, will lead to our successors having a different dental formula from our own. It is interesting to notice that



From Ambrose Birmingham, in Cunningham's *Text-Book of Anatomy.*

Fig. 2.—The Milk Teeth of the Left Side.

The masticating surfaces of the two upper molars are shown above. In the second row the upper teeth are viewed from the outer or labial side. In the third row the lower teeth are shown in a similar manner; and below are the masticating surfaces of the two lower molars. In the specimen from which the first upper molar was drawn the two outer or buccal cusps were not distinctly separated, as is often the case.

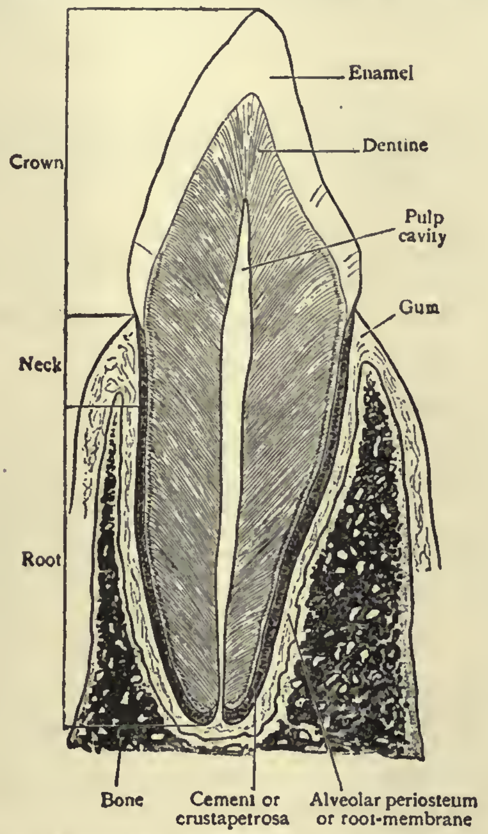
in some of the lower races of mankind the last molar tooth is nearly as large as those in front of it, and this is the case in the anthropoid apes. A. Keith and D. Braden Kyle have pointed out that the second and third molar teeth are successively formed in the posterior wall of the maxillary antrum and their crowns look backward. It is owing to the gradual growth backward of this antrum and the maxilla that they are rotated round a quarter of a circle and so at last look downward (see A. Keith, *British Journal of Dental Science*, vol. xlv., June 16, 1902).

Extra teeth are occasionally met with in the incisor, premolar and molar regions; their significance will be better realized after the embryology and comparative anatomy of the subject have been sketched.

For an accurate and detailed description of man's teeth see *A Manual of Dental Anatomy*, by C. S. Tomes, London, 1904.

Histology.

If a section be made vertically through a tooth all the exposed part or crown is seen to be covered with enamel, which, microscopically, is composed of a number of fine hexagonal prisms arranged at right angles to the surface of the tooth, and formed chiefly of calcium phosphate with small amounts of calcium carbonate, magnesium phosphate and calcium fluoride, but containing practically no organic matter. The enamel rests on the "dentine," of which hard yet elastic substance by far the greater part of the tooth is composed. It is made of the same salts as the enamel, but contains in addition a good deal of organic matter and forms a structureless mass through which the fine "dentinal tubes" run from the pulp cavity to the periphery.



From Ambrose Birmingham, in Cunningham's *Text-Book of Anatomy*.

Fig. 3.—Vertical Section of Canine Tooth, to illustrate its various parts, and its structure.

Surrounded by the dentine is the "pulp cavity," which is filled by the tooth pulp, a highly vascular and nervous mass of branched connective tissue cells, which, in a young tooth, has a layer of epithelial cells, the "odontoblasts," lying close against the wall of the cavity and forming new dentine. Slender processes ("Tomes's fibrils") project from these cells into the dentinal tubes, and are probably sensory. A nerve and artery enter the apex of the root of the tooth, but it is not understood how the nerve ends.

Surrounding the dentine where it is not covered by enamel is the "cement" or "crusta petrosa," a thin layer of bone which is only separated from the bony socket by the alveolar periosteum.

Embryology.

The lip is marked off from the rest of the mouth region by a "lip groove," which, in the case of the lower jaw, grows obliquely downward and backward, and the mass of ectodermal cells bounding it penetrates for some distance into the surrounding mesoderm below the bottom of the groove. This is known as the "tooth band."

On the under surface of this oblique tooth band (still taking the lower jaw), and close to its edge, appear ten thickenings, below each of which the mesoderm rises up into a "dental papilla," and so moulds the thickening into a cap for itself—the "enamel organ." The superficial cells of the dental papilla become the "odontoblasts" and manufacture the dentine, while those cells of the cap (enamel organ) which are on its concave surface and therefore nearest the dental papilla are called "ameloblasts," and form the enamel. The cutting or grinding part of the tooth is first formed, and the crown gradually closes round the dental papilla, so that at last, when the root is formed, the central part of the papilla remains as the pulp cavity surrounded by dentine except at the apex of the root. The roots, however, are formed slowly, and as a rule are not complete until some time after the tooth is cut. The mesoblastic connective tissue surrounding the developing tooth becomes condensed into a fibrous bag which is called the tooth-sac, and round this the lower jaw grows to form the alveolus. The crusta petrosa which covers the root is developed from the tooth-sac. It will therefore be seen that, of the various structures which make up a tooth, the enamel is derived from the ectoderm, while the dentine, pulp and crusta petrosa or cement are mesodermal.

So far only the milk dentition of the lower jaw has been accounted for.

Returning to the tooth band, it was noticed that the enamel organs were formed not at the extreme edge but a little way from it. From the extreme edge, which, it will be remembered, points inward toward the tongue, the permanent tooth germs are derived, and it is therefore clear that the permanent teeth must come up on the lingual side of their milk predecessors.

For further details and literature see *Dental Anatomy*, by C. S. Tomes, London, 1904; and *Development of the Human Body*, by J. P. McMurrich, London, 1906.

Comparative Anatomy.

The details of the teeth vary so greatly in different animals and groups of animals, and, on account of their being the most durable tissues of the body, are so important for classificatory purposes, that they are dealt with freely in the various zoological articles. All that can be done here is to give a broad general survey of the subject, taking the details of man's dentition, already set forth, as a point of departure.

In some fishes the teeth are continuous over the edges of the jaws with the scales on the surface of the body, and there is no doubt that teeth should be regarded as modified scales which have migrated into the mouth.

In the Cyclostomata (lampreys and hags) the teeth are horny cones, but beneath them there are papillae of the mesoderm covered with ectoderm which resemble the dental papillae and enamel organs although no calcification occurs except in Bdellostoma. In the Elasmobranchii (cartilaginous fishes) the teeth are arranged in several rows, and as those of the front row fall out the hinder row take their place; sometimes they are triangular and very sharp as in the sharks, sometimes flattened and arranged like a pavement for crushing as in rays. These teeth only represent the crowns of man's teeth, and they are not embedded in sockets except in the case of the teeth in the saw of the saw-fish (Pristis); moreover the dentine of which they are largely composed resembles bone and fills up the whole pulp cavity. From its structure it is known as *osteodentine*.

In the Teleostomi (teleostean and ganoid fishes) there is great variability; sometimes, as in the sturgeon, there are no teeth at all, while at others every bone bounding the mouth, including the branchial arches, bears teeth. As an example of a very full tooth armature the pike's mouth and pharynx may be instanced. Both in the pike and the hake hinged teeth occur; these bend backward during the passage of prey down the throat, but are re-erected by elastic ligaments. As a rule, the dentine of the Teleostomi is of the variety already described as osteodentine, but sometimes, as in the hake, it is vascular and is known as vasodentine.

In the Amphibia teeth are not so numerous as in the fishes, though like them they are not confined to the jaws, since vomerine teeth are very constant. The toad is edentulous, while the frog has no teeth in the lower jaw. An extinct order of tailed amphibians, the Stegocephali, are often called labyrinthodonts on account of the complex way in which the enamel is involuted into the interior of the teeth. Amphibians' teeth are usually anchylosed to the jaw, that is to say, directly united by bone.

In the Reptilia many and various arrangements of the teeth are found. In the Chelonia (turtles) there are no teeth, although the ectodermal ingrowth (dental band) from which they are developed in other animals is present in the embryo. The place of the teeth in these reptiles is taken by horny jaw-cases.

In the Ophidia the non-poisonous snakes have two rows of teeth in the upper jaw, one on the maxillae and another on the palatine and pterygoid bones, while in the lower jaw there is only one row. These teeth are sharp pegs anchylosed to the bones and so strongly recurved that one of these snakes would be unable, even if it wished to do so, to let any prey which had once entered its mouth escape. The poisonous snakes have a special poison fang in the maxilla of each side; these have a deep groove or canal running down them which transmits the poison from the poison gland. In the colubrine snakes, such as the cobra, the poison fang is always erect, but in the viperine, such as our own adder and the rattlesnake, there is a mechanism by which the tooth is only erected when the jaws are opened for striking. At other times the teeth lie flat in the roof of the mouth.

In the lizards or Lacertilia the teeth usually consist of a series of pegs in the upper and lower jaw, each resembling the one in front of it; sometimes, as in the chameleon, they are anchylosed by their bases to the bone, but at others, as in the iguana, they are fused by their sides to a ridge of bone which forms a low wall on their lateral surface. In the former case the dentition is spoken of as "acrodont," in the latter as "pleurodont."

In the Crocodilia the teeth are fitted into definite sockets as in mammals and are not anchylosed with the jaws. This arrangement is spoken of as "thecodont."

Existing birds are toothless, but palaeontology shows that they originally had teeth of a reptilian character.

In all these lower vertebrates, then, the teeth are similar or nearly similar in character; at least they are not divided into definite incisor, canine, premolar and molar regions. Their dentition is therefore known as "homodont." Another characteristic is that in almost all of them there is an arrangement for a continuous succession of teeth, so that when one is lost another from behind takes its place, and to this arrangement the term "polyphyodont" is applied. With a few exceptions a homodont dentition is also polyphyodont.

In the Mammalia the different groups of teeth (incisor, canine, &c.) already noticed in man are found, and these animals are characterized, with some exceptions, by having a "heterodont" as opposed to a homodont dentition. In the mammals too the polyphyodont or continuous succession of teeth is reduced to a "diphyodont" dentition, which means that there is only one relay of teeth to replace the first set. In the marsupials the reduction of the succession is carried still further, for only one premolar in each segment of the jaw is replaced, while in the toothed whales there is no succession at all. When one set has to do duty throughout life the dentition is called "monophyodont." There is a great deal of discussion as to how the complex back teeth of mammals with their numerous cusps were derived from the simple conical teeth which are generally assumed, though not by all, to have been the primitive arrangement. One simple way of accounting for the change is by the concrescence theory, namely that several conical homodont teeth have fused and so formed a single multitubercular tooth; but, although this process may be partly true, it does not account for all the facts at our disposal. Another theory, which is more favoured at the present time, is known as the "tritubercular," and is largely based on the researches of E. D. Cope and H. F. Osborn, two American palaeontologists. According to this theory a simple peg-like, or, as it is called, "haplodont," tooth develops two additional smaller pegs or cones, one in front and one behind the original main cone, possibly owing to the irritation of the teeth against which it bites in the other jaw. This is known as the triconodont stage, and it is found in some of the oldest extinct mammals. As a later adaptation it is found that the two small cones, the anterior of which is called the "paracone" and the posterior the "metacone," become external to the original "protocone" in the upper jaw and internal in the lower.

The surface of the tooth has now a triangular shape with a cone at each angle, and this is the "tritubercular tooth" which is of very common occurrence among the ancestral mammals. Other cusps may be developed later, and so the quadricuspid and quinquecuspid molar teeth of man and other mammals are accounted for. This theory, although in a brief outline it sounds feasible enough, has really many points of difficulty, and those who are interested in the subject will find a fuller account in C. S. Tomes' *Dental Anatomy* (London, 1904), and in W. L. H. Duckworth's *Morphology and Anthropology* (Cambridge, 1904), in both of which references to the original literature, which is now very voluminous, are given. Marett Tims (*J. Anat. and Phys.*, vol. xxxvii. p. 131) suggests that the evolution of the mammalian teeth is to be explained partly by the tritubercular and partly by the concrescence theory.

It is impossible, in the space assigned, to give even a brief review of mammalian odontology, but it may clear the ground for the special zoological articles if an attempt is made to define what is meant by the different classes of teeth.

Incisor teeth are those which in the upper jaw have their sockets in the premaxillary bone; they are generally chisel-shaped, and with their opponents of the lower jaw act like scissors. They are specially well marked in the rodents, and in these animals the pulp throughout life continues to form fresh dentine, so that the teeth are ever growing, and it is absolutely necessary for their owners to be continually gnawing in order to wear them away at their cutting edges. The tusks of the elephant and the single tusk of the male narwhal are modified incisors, while in the ruminants the incisor teeth are wanting in the upper jaw.

The *canine tooth* is the first tooth behind the premaxillo-maxillary suture, provided it be not far behind it; it is almost always the first of the premaxillary series, speaking accurately, which is elongated and sharply pointed. As its name implies it is well marked in dogs and other Carnivora, but is found in many other orders. It is the special offensive and defensive weapon of many mammals, and is greatly developed in some of the ungulates which are without horns, *e.g.*, the musk deer. The tusks of the walrus and wild boar are canines. In many of the Insectivora, especially the mole, the canine is very hard to identify, as in these animals an incisor or a premolar may take on caniniform characters, or there may be no tooth at all with these characters.

The *premolar teeth* are those in the maxillary bone which are preceded by milk teeth. This definition, of course, includes the canine as a modified premolar, and so it should no doubt be considered, though, if it is desired to keep it distinct, "behind the canine" must be added.

Unfortunately for an accurate definition the first premolar behind the canine is not always preceded by another tooth, and so it becomes an unsettled question whether, in these cases, the tooth is a retained milk tooth or a permanent one which has had no predecessor; it is probable, however, that the latter is the right interpretation.

The *molar teeth* are those, behind the premolars, which are not preceded by temporary teeth. As was pointed out, in man's dentition they are probably teeth of the first or milk dentition which appear late.

In front of the premolar teeth, and between them and the canine, if it be present, or the incisors, if it be absent, there is often a space called the "diastema." It is best marked in the orders of Rodentia and Ungulata, and in the horse is familiar as the place where the bit lies.

In recording the teeth of any particular mammal it saves time and space if a dental formula be used. This simply means setting down the number of each kind of tooth in one side of the upper and lower jaw in their order from before backward. Thus man's formula would be, incisors $\frac{2}{2}$, canines $\frac{1}{1}$, premolars $\frac{2}{2}$, molars $\frac{3}{3}$. This is condensed into $\frac{2.1.2.3}{2.1.2.3}$.

Some other types of dental formulae are—

Catarrhine (old world) monkeys	$\frac{2.1.2.3}{2.1.2.3}$
Platyrhine (new world) monkeys	$\frac{2.1.3.3}{2.1.3.3}$
Marmosets	$\frac{2.1.3.2}{2.1.3.2}$
Most lemurs	$\frac{2.1.2.3}{2.1.2.3}$
or	$\frac{2.1.3.3}{2.1.3.3}$
Insectivorous bats (full series) (The upper incisors and both premolars may be reduced by one)	$\frac{2.1.3.3}{3.1.3.3}$
Frugiverous bats (The molars may be reduced)	$\frac{2.1.2.3}{2.1.3.3}$
Insectivora (teeth variable and somewhat uncertain)	
Hedgehog	$\frac{3.1.3.3}{2.1.2.3}$
Mole (Five different dental formulae have been assigned to this animal)	$\frac{3.1.4.3}{3.1.4.3}$
Carnivora—	
Cat family (Felidae)	$\frac{3.1.3.1}{3.1.2.1}$
Dog family (Canidae), Bear family (Ursidae)	$\frac{3.1.4.2}{3.1.4.3}$
Civet family (Viverridae), Racoon family (Procyonidae)	$\frac{3.1.4.2}{3.1.4.2}$
Hyaena family (Hyaenidae)	$\frac{3.1.4.1}{3.1.3.1}$
Weasel family (Mustelidae)	$\frac{3.1.4.1}{3.1.4.2}$
Eared seal family (Otariidae)	$\frac{3.1.4.1 \text{ or } 2}{2.1.4.1}$
Seal family (Phocidae)	$\frac{3.1.4.1}{3.1.4.1}$
Walrus family (Trichechidae), adult	$\frac{1.1.3.0}{0.1.3.0}$
In a young animal (probably)	$\frac{3.1.3.2}{3.1.3.1}$

Ungulata—

Hippopotamus	$\frac{2.1.4.3}{2.1.4.3}$
Pig family (Suidae)	$\frac{3.1.4.3}{3.1.4.3}$
Camel	$\frac{1.1.3.3}{3.1.2.3}$
Chevrotain (Tragulidae)	$\frac{0.1.3.3}{3.1.3.3}$
Deer family (Cervidae)	$\frac{0.(0 \text{ or } 1).3.3}{3.1.3.3}$
Hollow-horned ruminants (Bovidae)	$\frac{0.0.3.3}{3.1.3.3}$
Tapir	$\frac{3.1.4.3}{3.1.3.3}$
Horse (Equidae)	$\frac{3.1.3.3}{3.1.3.3}$
Rhinoceros	$\frac{(0-2).0.4.3}{(0-1).(0-1).4.3}$
Procavia (Hyrax)	$\frac{(1-2).0.4.3}{2.0.4.3}$
Elephant	$\frac{\text{d.i. 1. i. 1. c. 0. d.m. } (3-4) \text{ m. } 3}{0 \quad 0 \quad 0 \quad (3-4) \quad 3}$

In this animal there are no premolars, but the milk molars (d.m) and true molars gradually replace one another from before backward throughout life, so that there are never more than two back teeth in each segment of the jaw at any one time.

Rodentia—

Typical rodents (Simplicidentata)	$\frac{1.0.(0-1).3}{1.0.(0-1).3}$
Hares and rabbits (Duplicidentata)	$\frac{2.0.3.3}{1.0.2.3}$

Cetacea.—In the living toothed whales (Odontoceti) the dentition is homodont and may be as great as $\frac{60}{60}$. There is every reason to believe, however, that they are derived from heterodont ancestors. In the whalebone whales (Mystacoceti) the teeth are replaced by the whalebone in the adult, but in the embryo slightly calcified teeth are present which are afterwards absorbed.

The homodont dentition of the whales is a retrograde process, and is therefore not comparable to the homodont dentition of the vertebrates below mammals.

Sirenia.—The dentition is monophyodont. The manatee has i. $\frac{2}{2}$, c. $\frac{0}{0}$, back teeth $\frac{11}{11}$.

In the Edentata the ant-eaters (Myrmecophagidae) and pangolins (Manidae) are toothless, though the latter have foetal tooth germs. The aard varks (Orycteropodidae) are somewhat heterodont, while the armadillos (Dasypodidae) and sloths (Bradypodidae) have a homodont dentition, which, like that of the whales, is retrogressive. In the giant armadillo (*Priodon gigas*) the formula is $\frac{25}{25}$. This animal therefore has a hundred teeth. In none of the Edentata are the teeth covered with enamel.

In the Marsupialia the typical formula is $\frac{3.1.3.4.}{3.1.3.4.}$ They are divided into *diprotodont*, in which there are not more than $\frac{3}{3}$ incisors, often $\frac{3}{1}$ as in kangaroos, and *polyprotodont*, in which the incisors are more than $\frac{3}{3}$, as in the Tasmanian wolf (Thylacinus) and Tasmanian devil (Sarcophilus). The marsupial teeth are often regarded as all milk teeth, yet the order is not really monophyodont because the germs of the permanent teeth are formed and aborted. Modern research, however, casts grave doubt on the accuracy of this view.

In the Monotremata the Echidna or spiny ant-eater is quite edentulous, while the duck-mole (Ornithorhynchus) has functional molar teeth in youth, though in the adult these are lost, and their place is taken by horny plates.

Reviewing the various tooth formulae of mammals the following is usually regarded as typical:—

$$\frac{3.1.4.3}{3.1.4.3}$$

This, it will be noticed, is the formula of the pig, and it is also that of almost all the Eocene Ungulata. Although the majority of mammals are diphyodont, or, in other words, the working teeth belong to two dentitions, evidences have lately been submitted of vestiges of two other series, one on the labial side of the milk teeth and one on the lingual side of the permanent series. If these are substantiated there would be four dentitions—(1) premilk; (2) milk; (3) permanent; (4) post-permanent. The theory, though it bridges over the gap between the polyphyodont lower vertebrates and the apparently diphyodont mammals, is not by any means established. As the teeth are of such importance in the classification of animals, it will save continually repeated explanations in other articles if some of the chief terms by which they are described are recapitulated and briefly defined here.

1. *Acrodont*, a tooth which is anchylosed by its base to the summit of a parapet on the jaw.
2. *Bilophodont*, a molar tooth having two transverse ridges on its grinding surface, as in the tapir.
3. *Brachyodont*, a low-crowned molar tooth—the opposite of hypsodont.
4. *Bunodont*, a tooth bearing conical cusps.
5. *Diphyodont*, having two series of teeth (milk and permanent).
6. *Diprotodont*, a marsupial with not more than $\frac{3}{3}$ incisors, often only one on each side of the mandible.
7. *Haplodont*, a tooth having a simple conical crown with a single root.
8. *Heterodont*, a dentition in which the teeth are not all alike, chiefly characteristic of the Mammalia.
9. *Homodont*, a dentition in which the teeth are all alike as in many of the lower vertebrates and some mammals.
10. *Hypsodont*, a high-crowned molar tooth, such as that of the horse,—the opposite to brachydont.
11. *Lophodont*, a transversely ridged molar tooth; cf. bilophodont.
12. *Monophyodont*, having only one dentition (cf. diphy- and polyphy-odont).
13. *Multituberculate*, a tooth, the crown of which bears numerous conical cusps; held by some to be the primitive condition of the mammalian teeth.
14. *Pleurodont*, a tooth anchylosed to the inner side of a parapet on the jaw.
15. *Polybunodont*, a synonym for multituberculate.
16. *Polyphyodont*, having an endless succession of teeth, as in most vertebrates below the mammals.
17. *Polyprotodont*, a marsupial having an incisor formula of more than $\frac{3}{3}$.
18. *Protodont*, a stage met with in fossil mammals which is an advance on the haplodont tooth in that two small cusps are added to the main cone.
19. *Secodont*, a back tooth adapted to cutting as in many of the Carnivora.
20. *Selenodont*, a molar tooth with crescentic ridges on its grinding surface as in most ruminants.
21. *Thecodont*, a tooth embedded in a socket or alveolus, as in mammals.
22. *Triconodont*, a fossil stage in advance of the protodont. There are three well-marked cones in an antero-posterior line.
23. *Tritubercular*, a fossil stage succeeding the triconodont. The main cone is external in the lower teeth and internal in the upper. A very common form of back tooth in fossil forms and one which gives its name to the "tritubercular theory." (F. G. P.)

TEETOTALISM, the practice of total abstinence from all intoxicating liquors, hence that form of the temperance movement of which the basis is the "pledge" to abstain from all intoxicating liquors (see TEMPERANCE). There seems no doubt that the word, whatever its actual origin, is a strengthened form of "total," probably influenced by "teetotum" (*q.v.*). According to the *Century Dictionary*, the secretary of a New York temperance society introduced a total abstinence pledge among its members, who were thus divided into those who had taken the old pledge, the O.P.'s, to abstain from spirituous liquors, and the T.'s, who had taken the new or total pledge. The English version, taken from the account by Joseph Livesey in the *Staunch Teetotaler*, January 1867, is that one Richard Turner, a Preston artisan and popular temperance speaker, declared at a meeting about 1833, that "nothing but tee-tee-total would do." This repetition of the initial letter does not appear to have been due to his stammering but to have been a mere emphasis on the word. The expression seems to have obtained instant recognition and popularity. Both versions are apparently authentic, and there seems no reason to suppose that they are not independent.

TEETOTUM, a form of top, used in various games of chance; the body is of polygonal shape, marked with letters or numbers, which decide the result of the game, according to the side which remains uppermost on the fall of the top after spinning. Strutt, who was born in 1749, mentions (*Sports and Pastimes*) the teetotum as used in games when he was a boy. It seems that in its earliest form the body was square, marked on the four sides by the letters A. (Lat. *aufer*, take up or away), indicating that the player takes one from the pool, D. (Lat. *depone*, put down), when a fine has to be paid, N. (Lat. *nihil*, nothing), and T. (Lat. *totum*), when the whole pool is taken. Other accounts give such letters as P.N.D. (*dimidium*, half), or H. and T. or other combinations of letters.

TEGEA, an ancient Greek city of Arcadia, situated on a plateau which is enclosed by Mts. Parthenium and Maenalus on E. and W., and by two transverse ranges which separate it from the plateau of Orchomenus and the Eurotas valley respectively. The Tegean territory occupied the southern part of this space; the northern half, sundered by projecting spurs from the parallel ranges, belonged to Mantineia. The entire plain was well adapted for pasturage and corn-growing, but was liable to floods owing to the lack of free outlets for its water-courses. Hence the regulation of the *zerethra* or subterranean conduits which drained away the overflow southward was a matter of vital importance both to Tegea and to Mantineia, and a cause of frequent quarrels. By its vicinity to the watersheds of the Eurotas and Alpheus, and its command over the main roads from Laconia to Argos and the Isthmus, Tegea likewise was brought into conflict with Sparta.

Tegea was one of the most ancient cities of Peloponnesus; tradition ascribed its concentration (*synoecism*) out of eight or nine primitive cantons to a mythical king Aleus. From the fact that several Cretan townships passed for colonies of Tegea, it may be inferred that this city had oversea connexions in prehistoric days. The prominence which legend assigns to its king Echemus in opposing the Heraclid invasion shows that it was one of the chief Peloponnesian communities in the pre-Dorian epoch. For several centuries Tegea served as a bulwark of Arcadia against the expanding power of Sparta; though ultimately subdued about 550 B.C. it was allowed to retain its independence and its Arcadian nationality. During the Persian invasion the Tegeans displayed a readiness unusual among Peloponnesian cities; in the battle of Plataea they were the first to enter the enemy's camp. A few years later they headed an Arcadian and Argive league against Sparta, but by the loss of two pitched battles (Tegea and Dipaea) were induced to resume their former loyalty (about 468–467). In 423 they broke out into open war with the Mantineians, and when the latter rebelled against Sparta and allied themselves with Argos and Athens, the Tegeans stood firmly by Sparta's side: in the decisive battle of Mantineia (418) their troops had a large share in the overthrow of the coalition. During the early 4th century before Christ Tegea continued to support Sparta against the Mantineians and other malcontents. After the battle of Leuctra the philo-Laconian party was expelled with Mantineian help. Tegea henceforth took an active part in the revival of the Arcadian League and the prosecution of the war in alliance with Thebes against Sparta (371–362), and the ultimate defection of Mantineia confirmed it in its federalist tendencies. The foundation of the new federal capital Megalopolis threw Tegea somewhat into the shade. It showed itself hostile to the Macedonians, and in 266 joined the Chremonidean League against Antigonus Gonatas. To the incorporation of Mantineia into the Achaean League (233) Tegea replied by allying itself with the Aetolians, who in turn made it over to Cleomenes III. of Sparta (228). From the latter it was transferred by Antigonus Doson to the Achaean League (222); in 218 it was again occupied by the Spartans but reconquered in 207 by the Achaean general Philopoemen. In Augustus' time Tegea was the only important town of Arcadia, but its history throughout the Roman and Byzantine periods is obscure; it ceased to exist as a Greek city after the Gothic invasion of 395. During the Frankish occupation its place was taken by the fortress of Nikli. At the time of the Turkish conquest (1458) Nikli had been superseded by a fair-sized town called Mouchli, which in turn disappeared when the new city of Tripolitsa was founded about 3 m. N.W. The site is now occupied by the small village of Piali.

Archaeology.—The temple of Athena Alea at Tegea is described by Pausanias as excelling all others in the Peloponnese both in size and in beauty of construction. The original temple was said to have been built by Aleus, the founder of the city; it was superseded by a larger one which was destroyed by fire in 395 B.C. The rebuilding was entrusted to Scopas, the great sculptor; and it is probable that he not only acted as architect, but also provided the sculptural groups which ornamented the pediments. Like the temple at Phigalia, it combined the forms of all three orders—Doric, Ionic and Corinthian. Pausanias asserts that the outer order was Ionic; but excavations have proved that it was Doric. The pedimental groups of the temple represented at the front, the hunt of the Calydonian boar, and, at the back, the battle of Achilles and Telephus. Both subjects were intimately associated with the temple, for Atalanta had dedicated in it the face and tusks of the boar, which had been awarded to her as the first to wound it; and Telephus was the son of Heracles and the priestess Auge. Two heads of heroes and that of the boar were found before 1880; later excavation, in 1883, showed the plan of the temple, which had six columns at front and back, and thirteen at the sides. In 1900 the French school at Athens recovered more fragments of sculpture, including a head of Heracles and the torso and possibly the head of Atalanta, these last two of Parian marble. The other heads are badly damaged owing to the fact that the white marble from Doliana, of which they are made, does not resist damp. But they still show in the intensity of their expression the power of expressing passion for which Scopas was famous beyond all other ancient sculptors. See GREEK ART, fig. 63.

TEGERNSEE, a lake of Germany, in the province of Upper Bavaria, situated in a beautiful mountain country, 2382 ft. above the sea, 34 m. S. from Munich by rail to Gmund, a village with a station on the north shore. The lake is 4 m. long, averages $1\frac{1}{4}$ m. broad, and is about 235 ft. deep. Its waters discharge through the Mangfall into the Inn. The southern part is environed by high and well-wooded hills, while on the northern side, where it debouches on the plain, the banks are flat and less attractive. Prosperous villages and handsome villas stud its shores, and it is one of the most frequented summer resorts in the vicinity of Munich.

The village of Tegernsee (pop. 1742 in 1905), on the east bank, has a parish church dating from the 15th century, a ducal castle which was formerly a Benedictine monastery, and a hospital, founded in connexion with the large ophthalmic practice of the late Duke Charles Theodore of Bavaria.

See Freyberg, *Aelteste Geschichte von Tegernsee* (Munich, 1822); Hack, *Tegernsee* (Munich, 1888); Breu, *Der Tegernsee, limnologische Studie* (Munich, 1906).

TEGETTHOFF, WILHELM VON, BARON (1827–1871), Austrian admiral, son of Lieutenant-Colonel Karl von Tegetthoff, was born at Marburg, in Styria, on the 23rd of December 1827. After passing through the naval college at Venice, he first served afloat in 1845, and in 1848 was made an ensign. In 1849 he was present at the blockade of Venice, resulting in its surrender. In 1852 he was promoted to be a lieutenant, and during the Crimean war was employed on a sort of police duty at the Sulina mouth of the Danube, which brought him to the favourable notice of the Archduke Maximilian, who in 1854 had been appointed head of the navy with the style of rear-admiral. After some time in a semi-official scientific expedition in Egypt, Arabia, and the Red Sea down to the island of Socotra, Tegetthoff was promoted to the rank of captain of the third class, and in 1858 he commanded the corvette "Erzherzog Friedrich" on the coast of Morocco, then in a very disturbed state. The corvette returned to Trieste on the imminence of the war with France; but during 1859 the French fleet commanded the Adriatic in vastly superior force, against which the Austrians were powerless. After the peace Tegetthoff made a voyage to Brazil as aide-de-camp to Maximilian, and in 1860–63 commanded a large frigate in the Levant during the disturbances in Syria, and on the coast of Greece or in the Piraeus at the time of the Greek revolution. Towards the end of 1863 he was sent to the North Sea as commodore in command of two frigates, with which, together with three small Prussian gunboats, he fought an action with the Danish squadron, and though without any decisive success, succeeded in raising the blockade of the mouths of the Elbe and Weser. The Austrian emperor answered Tegetthoff's telegraphic despatch by another promoting him to be rear-admiral, and conferring on him the Order of the Iron Crown. In 1865 he commanded a small squadron in the Mediterranean, and in the war of 1866 was placed in command of the whole effective force of the Austrian navy. With all his efforts, however, this was markedly inferior to the Italian force opposed to it, and when the two fleets met off Lissa on the 20th of July, the decisive victory of the Austrians was entirely due to the personal superiority of Tegetthoff and the officers whom he in great measure had trained. In numbers, in ships, and in armament the Italians were much the more powerful, but they had neither a capable chief nor efficient officers. Tegetthoff was immediately promoted, by telegraph, to the rank of vice-admiral, and among the many decorations conferred on him was one from his former commander, the unfortunate Maximilian, at this time emperor of Mexico, whose body was in the following year brought home by Tegetthoff. In March 1868 he was appointed head of the naval section of the War Office and commander-in-chief of the navy, which offices he held till his death at Vienna, after a very short illness, on the 7th of April 1871—in the words of the semi-official notice—"zu früh für Österreich."

(J. K. L.)

TEGGIANO (anc. *Tegianum*, formerly called *Diano*), a town in Campania, Italy, in the province of Salerno, 45 m. S.E. of that town. Pop. (1901) 5095. It is situated 2090 ft. above sea-level on an isolated eminence above the upper part of the valley of the Negro (anc. *Tanager*), to which it gives the name of Val di Diano. It represents the ancient Tegianum a municipal town of Lucania, made into a colony by Nero, of which the ruins can be traced at the foot of the hill, with an ancient Roman bridge. An Oscan sepulchral inscription in Greek letters has been found here (cf. W. Corssen in *Ephemeris Epigrafica*, ii. 153). It possesses a castle, several churches of some interest, and three conventual buildings. In 1497 it was strong enough to resist, under Antonio Sanseverino of Salerno, the siege undertaken by Frederick of Aragon. (T. As.)

TEGNÉR, ESAIAS (1782–1846), Swedish writer, was born on the 13th of November 1782, at Kyrkerud in Wermland. His father was a pastor, and his grandparents on both sides were peasants. His father, whose name had been Esaias Lucasson, took the surname of Tegnerus—altered by his fifth son, the poet, to Tegnér—from the hamlet of Tegnaby in Småland, where he was born. In 1792 Tegnerus died. In 1799 Esaias Tegnér, hitherto educated in the country, entered the university of Lund, where he graduated in philosophy in 1802, and continued as tutor until 1810, when he was elected Greek lecturer. In 1806 he married Anna Maria Gustava Myhrman, to whom he had been attached since his earliest youth. In 1812 he was named professor, and continued to work as a lecturer in Lund until 1824, when he was made bishop of Vexiö. At Vexiö he remained until his death, twenty-two years later. Tegnér's early poems have little merit. He was comparatively slow in development. His first great success was a dithyrambic war-song for the army of 1808, which stirred every Swedish heart. In 1811 his patriotic poem *Svea* won the great prize of the Swedish Academy, and made him famous. In the same year was founded in Stockholm the Gothic League (*Götiska förbundet*), a sort of club of young and patriotic men of letters, of whom Tegnér quickly became the chief. The club published a magazine, entitled *Iduna*, in which it printed a great deal of excellent poetry, and ventilated its views, particularly as regards the study of old Icelandic literature and history. Tegnér, Geijer, Afzelius, and Nicander became the most famous members of the Gothic League. Of the very numerous poems written by Tegnér in the little room at Lund which is now shown to visitors as the Tegnér museum, the majority are short, and even occasional lyrics. His celebrated *Song to the Sun* dates from 1817. He completed three poems of a more ambitious character, on which his fame chiefly rests. Of these, two, the romance of *Axel* (1822) and the delicately-chiselled idyl of *Nattvardsbarnen* ("The First Communion," 1820), translated by Longfellow, take a secondary place in comparison with Tegnér's masterpiece, of world-wide fame. In 1820 he published in *Iduna* certain fragments of an epic or cycle of epical pieces, on which he was then working, *Frithjofs saga* or the Story of Frithiof. In 1822 he published five more cantos, and in 1825 the entire poem. Before it was completed it was famous throughout Europe; the aged Goethe took up his pen to commend to his countrymen this "alte, kräftige, gigantisch-barbarische Dichtart," and desired Amalie von Imhoff to translate it into German. This romantic paraphrase of an ancient saga was composed in twenty-four cantos, all differing in verse form, modelled somewhat, it is only fair to say, on an earlier Danish masterpiece, the *Helge* of Öhlenschläger. *Frithjofs saga* is the best known of all Swedish productions; it is said to have been translated twenty-two times into English, twenty times into German, and once at least into every European language. It is far from satisfying the demands of more recent antiquarian research, but it still is allowed to give the freshest existing impression, in imaginative form, of life in early Scandinavia. In later years Tegnér began, but left unfinished, two important epical poems, *Gerda* and *Kronbruden*. The period of the publication of *Frithjofs saga* (1825) was the critical epoch of his career. It made him one of the most famous poets in Europe; it transferred him from his study in Lund to the bishop's palace in Vexiö; it marked the first breakdown of his health, which had hitherto been excellent; and it witnessed a singular moral crisis in the inner history of the poet, about which much has been written, but of which little is known. Tegnér was at this time passionately in love with a certain beautiful Euphrosyne Palm, the wife of a town councillor in Lund, and this unfortunate passion, while it inspired much of his finest poetry, turned the poet's blood to gall. From this time forward the heartlessness of woman is one of Tegnér's principal themes. It is a remarkable sign of the condition of Sweden at that time that a man not in holy orders, and so little in possession of the religious temperament as Tegnér, should be offered and should accept a bishop's crosier. He did not hesitate in accepting it: it was a great honour; he was poor; and he was anxious to get away from Lund. No sooner, however, had he begun to study for his new duties than he began to regret the step he had taken. It was nevertheless too late to go back, and Tegnér made a respectable bishop as long as his health lasted. But he became moody and melancholy; as early as 1833 he complained of fiery heats in his brain, and in 1840, during a visit to Stockholm, he suddenly became insane. He was sent to an asylum in Schleswig, and early in 1841 he was cured, and able to return to Vexiö. It was during his convalescence in Schleswig that he composed *Kronbruden*. He wrote no more of importance; in 1843 he had a stroke of apoplexy, and on the 2nd of November 1846 he died in Vexiö. From 1819 he had been a member of the Swedish

Academy, where he was succeeded by his biographer and best imitator Böttiger.

See Böttiger, *Teckning af Tegnérs Lefnad*; Georg Brandes, *Esaias Tegnér*; Thommander, *Tankar och Löjen*. (E. G.)

TEGUCIGALPA, the capital of Honduras and of the department of Tegucigalpa; situated 3200 ft. above sea-level, on the river Choluteca, and at the head of a railway to the port of San Lorenzo on Fonseca Bay. Pop. (1905) about 35,000. Tegucigalpa is the largest and finest city in the republic. The majority of its houses are of one storey, built round a central court; the windows are usually unglazed but protected by iron bars which project into the narrow cobble-paved streets. The focus of civic life is near the central park, in which stands a bronze equestrian statue of Francisco Morazan (1792–1842), the Hondurian statesman and soldier. Fronting the park is a domed cathedral, one of the largest and most ornate churches in Honduras. Other noteworthy buildings are the government offices, university, school of industry and art, national printing works, and law courts. A lofty ten-arched bridge over the Choluteca connects the city with its principal suburb, Concepcion or Comayaguela. Tegucigalpa became capital of Honduras, a status it had previously shared with Comayagua, in 1880. During the 18th century the neighbourhood was famous for its gold, silver and marble, but in modern times the mines and quarries have greatly declined in value, and farming is the chief local industry. In 1907 Tegucigalpa was occupied by the Nicaraguan invaders.

TEGULA, the Latin term for the convex covering tile of a roof, as distinguished from the *imbrex*, the concave tile (see TILES).

TEHERAN (more properly TEHRAN), a province of Persia, with capital of the same name (which is also the capital of the Persian empire). It pays a yearly revenue of about £100,000, and comprises the districts of Saujbulagh, Shahriar, Feshaviyeh, Shimran, Kasran and Veramin. The first three, situated north-west, west and south of the city of Teheran, are very fertile, and supply the capital with grain, grapes and melons. Shimran, the district north of the city, and on the slopes of the Elburz (rising to an elevation of 12,600 ft.) has 63 villages (one, Tajrish, the seat of the governor, with a population of over 3000), which are much frequented during the summer months by the inhabitants of the city seeking relief from the great heat. One of the villages, Gulhek or Gulahek, but correctly Kulhek (with a guttural K, and meaning a small, reedy mere), situated 800 ft. above the city of Teheran and 6½ m. from it, was given in fief to the British government by Fath Ali Shah about 1830 for the summer quarters of the British legation. Zergendeh, a village adjoining Gulhek, is held in a similar manner by the Russian government, and the Russian legation stays there during the summer. Kasran is a hilly district north-east of Teheran, with numerous coal mines (inferior coal of the Jurassic period) and streams abounding with salmon trout. The Veramin district, south-east of Teheran city, has 123 villages, and supplies the city and surrounding districts with wheat, barley and rice. It is watered by the Jajrud river, and is considered one of the most fertile districts of Persia.

TEHERAN, the capital of Persia and of the province of the same name, 70 m. S. of the southern shore of the Caspian Sea. It is situated on an immense gravel deposit which slopes down from the foot of the Elburz mountain (rising to an altitude of 12,600 ft.) 8 or 9 m. N. of the city, and extends for 16 m. to near Shah-abdul-Azim, 5½ m. S. of it. Teheran was formerly a kind of polygon about 4 m. in circumference, with a mud wall and towers, a dry ditch and six gates, but in 1869 Nasr-ud-din Shah decided upon enlarging the city; the old wall and towers were demolished, the ditch was filled up and used for building sites, and an enceinte consisting of a ditch and 58 unequal bastions according to Vauban's first system was constructed and completed in 1874. The city then took the shape of an irregular octagon, and its circumference (a line through the salient angles of the bastions) measures 19,596 metres, or 12·18 m. The area within the bastions is about 7½ sq. m. There are twelve gates, which are closed from two hours after sunset to an hour before sunrise. According to observations taken in 1895 by British officers in connexion with determining the longitude of Madras, the longitude of Teheran (pillar at the north-western corner of the British legation grounds) is 51° 25′ 2·8″ E. The latitude of the old telegraph office, which was situated almost due S., is 35° 41′ 6·83″ N., and its elevation 3810 ft. The northern gates of the city are 282 ft. above the southern ones. Teheran has little to distinguish it in general outward appearance from other cities of the country, though in recent years (since the above-mentioned extension) many broad and straight streets and a number of buildings of western architecture, shops with show windows, electric lamps, cabs, &c., have been introduced. "We are in a city which was born and nurtured in the East, but is beginning to clothe itself at a West-End tailor's" (Curzon). Most of the innovations are to be seen only in the northern part of the town where the Europeans and many well-to-do natives reside. The ark or citadel, situated nearly in the centre of the town, contains the shah's palace and a number of modern buildings of respectable appearance, for instance the foreign office, the war office, customs, telegraph station, arsenal, &c. Immediately north of the ark are the Maidan Tupkhaneh (Artillery Square), 270 yds. by 120, and the great Maidan i Mashk (Maidan of drill), the military parade ground, 550 yds. by 350. South of the ark are the bazaars, the central arcade and caravanserai built *c.* 1850 by the prime minister Mirza Taki Khan, commonly known as the amir, and beyond them, as well as on the east and west, are the quarters of the old town, with narrow, crooked and mostly unpaved and unclean streets. Teheran has 6½ m. of tramways (single lines) and is connected with Shah-abdul-Azim by a single line of railway of one-metre gauge and 5½ m. long (the only railway in Persia). Water is freely supplied to the town by means of about thirty underground canals (*kanats*), led from the slope of the northern hills and running 5 to 10 m. at considerable depths below the surface. The water supply would be ample for the requirements of the population if it could be regularly and equally distributed; but the supply in the months of October and November is only about one-half of that during March, and much water is lost through open ditches and by leakage. The distribution therefore is irregular: in winter and early spring, when the gardens require very little water from the canals, the supply is too great, and in summer it is too little. It has been calculated that the mean water supply amounts to the enormous quantity of 921,000 gallons per hour all the year round, but that, after deducting the quantity wasted in distribution, irrigation of gardens, filling tanks and baths, watering streets, &c., there remain forty-two gallons per head daily during the month of April, seventeen during July, August and September, and ten during October and November. Even the last quantity would suffice if evenly distributed, but as most of the canals are private property and independent of government or municipal control, the distribution is unequal, and it frequently happens that when some parts of the city have water in abundance others have hardly any. Teheran has many mosques, all of recent date, the finest being the one called Masjed i Sipahsalar, built by Mirza Husain Khan Sipahsalar Azam, who was prime minister for ten years until 1884. It is situated in the new part of the city and adjoining it is the Baharistan palace, once the residence of Sipahsalar, afterwards occupied by the national assembly. Another notable mosque is the Masjed i Shah, completed *c.* 1840. There are also many colleges and schools, some of them with European teachers, including the "German School" (1907) with a yearly subsidy of £2200 from the shah. Before Nasr-ud-din's first voyage to Europe in 1873 only four western states had legations and consulates at Teheran; now twelve states are represented.

The present population of Teheran is about 280,000, including 600 Europeans, 4000 Jews, the same number of Armenians, 200 Zoroastrians, and a garrison of 3000 to 4000. The climate is considered unhealthy, particularly in the summer and early autumn, when typhoid, ague and other fevers are prevalent, but something in the way of sanitation has been effected and there is a distinct improvement. The author of the *Zīnat el majālis*, writing in 1596, states that cholera frequently visited the city, and, the north being shut off by high mountains, the air was hot and evil-smelling and the water unwholesome, in fact the climate was so bad that even the Angel of Death ran away from it. The mean yearly temperature calculated from observations taken for a number of years ending 1902 was 62·6° F., the highest temperature observed was 111°, the lowest 3°, giving a difference of 108° between extremes. The hottest month is July, with a mean of 85·2°, the coldest January, with a mean of 34·25°. The mean annual rainfall during a period of 15 years ending 31st December 1907, was 10 ins.

In the *Jehankusha i Juvaini*, a Persian history written in the 13th century, the name of the town is written Tiran, while other works have the name as it is now written, viz. Tehran. The latter spelling is due to Arab influence, old Persian names being frequently Arabicized and sometimes becoming unrecognizable. Two villages in the neighbourhood of Isfahan appear as Tiran in old documents, while in modern revenue accounts and lists they are written Tehran. The *Mujem el Buldan*, a geographical dictionary written in 1224, describes Teheran as a village 4 m. distant from Rai (Rhages). Pietro della Valle, who passed a night (June 6–7, 1618) at Teheran, writes "Taheran" (perhaps thinking it to be a plural of *taher*, "the pure"), and Sir Thomas Herbert, who visited it on the 14th of June 1627, calls it "Tyroan," and states that it contained 3000 houses built of sun-dried bricks and had its water supply from a little river which flowed through it in two branches. Almost the whole of the city was destroyed by the Afghans in 1723, and Teheran did not regain any importance until the close of the century when Agha Mahommed Khan, the founder of the Kajar dynasty, made it his capital and residence. Dr Olivier, who visited Teheran in 1796, says, "In spite of Agha Mohammed Khan's efforts to induce people to settle and merchants and manufacturers to establish themselves there, the population of Teheran does not amount to 15,000 souls, including a garrison of 3000." (A. H.-S.)

TEHRI, a native state in Northern India, in political subordination to the United Provinces: area, 4200 sq. m.; population (1901) 268,885; estimated revenue, £28,000. It lies entirely amid the Himalayas, containing ranges from 20,000 to 23,000 ft. above sea-level, and also the sources of both the Ganges and the Jumna, with the places of pilgrimage associated with them. The forests, which have been leased to the British government, are very valuable, yielding several kinds of pine, oak and cedar. The crops are rice, small millets, wheat, potatoes and a little tea. The chief, whose title is raja, is descended from a Rajput family which formerly ruled over all Garhwal. The existing state was created by the British after the war with Nepal in 1815. The town of Tehri, on the river Bhagirathi (as the Ganges is here called) has a pop. (1901) of 3387.

TEHUANTEPEC (from *tecuani-tepec*—"jaguar-hill"), the town which gives its name to the isthmus, gulf and railway, stands on the Tehuantepec river about 15 m. from its mouth and 13 m. by rail from Salina Cruz. Pop. (1904, estimated) 10,000. It is a typical, straggling Indian town, occupying the slope of a hill on the Pacific side of the divide, with a beautiful view of the river valley and the distant sierras to the N. The streets are little more than crooked paths up the hillside, and the habitations are for the most part thatched, mud-walled huts. The population of the town and of the surrounding district is composed almost wholly of Indians of the great Zapoteca family. The Tehuanas of Tehuantepec are noted for the beauty and graceful carriage of their women, who are reputed to be the finest-looking among the native races of Mexico. The women are the traders in Tehuantepec and do little menial work—a result, apparently, of the influence of beauty. The local industries include the making of "caña," a cane spirit, and the weaving of cotton fabrics, dyed with the juice of a marine shell-fish (*Purpura patula*) found on the neighbouring coast. Indigo was formerly grown in the vicinity and cochineal gathered for export, but both of these industries have declined.

TEHUANTEPEC, an isthmus of Mexico lying between the Gulfs of Campeche (Campeachy) and Tehuantepec, with the Mexican states of Tabasco and Chiapas on the E., and Vera Cruz and Oaxaca on the W. It includes that part of Mexico lying between the 94th and 96th meridians of W. longitude, or the south-eastern parts of Vera Cruz and Oaxaca, with perhaps small districts of Chiapas and Tabasco. It is 125 m. across at its narrowest part from gulf to gulf, or 120 m. to the head of Laguna Superior on the Pacific coast. The Sierra Madre breaks down at this point into a broad, plateau-like ridge, whose elevation, at the highest point reached by the Tehuantepec railway (Chivela Pass) is 735 ft. The northern side of the isthmus is swampy and densely covered with jungle, which has been a greater obstacle to railway construction than the grades in crossing the sierra. The whole region is hot and malarial, except the open elevations where the winds from the Pacific render it comparatively cool and healthful. The annual rainfall on the Atlantic or northern slope is 156 in. (Enock) and the maximum temperature about 95° in the shade. The Pacific slope has a light rainfall and dryer climate.

Since the days of Cortés, the Tehuantepec isthmus has been considered a favourable route, first for an interoceanic canal, and then for an interoceanic railway. Its proximity to the axis of international trade gives it some advantage over the Panama route, which is counterbalanced by the narrower width of the latter. When the great cost of a canal across the isthmus compelled engineers and capitalists to give it up as impracticable, James B. Eads proposed to construct a quadruple track ship-railway, and the scheme received serious attention for some time. Then came projects for an ordinary railway, and several concessions were granted by the Mexican government for this purpose from 1857 to 1882. In the last-named year the Mexican government resolved to undertake the enterprise on its own account, and entered into contracts with a prominent Mexican contractor for the work. In 1888 this contract was rescinded, after 67 m. of road had been completed. The next contract was fruitless through the death of the contractor, and the third failed to complete the work within the sum specified (£2,700,000). This was in 1893, and 37 m. remained to be built. A fourth contract resulted in the completion of the line from coast to coast in 1894, when it was found that the terminal ports were deficient in facilities and the road too light for heavy traffic. The government then entered into a contract with the London firm of contractors of S. Pearson & Son, Ltd., who had constructed the drainage works of the valley of Mexico and the new port works of Vera Cruz, to rebuild the line and construct terminal ports at Coatzacoalcos, on the Gulf coast, and Salina Cruz, on the Pacific side. The work was done for account of the Mexican government. Work began on the 16th of December 1899, and was finished to a point where its formal opening for traffic was possible in January 1907.

The railway is 192 m. long, with a branch of 18 m. between Juile and San Juan Evangelista. The minimum depth at low water in both ports is 33 ft., and an extensive system of quays and railway tracks at both terminals affords ample facilities for the expeditious handling of heavy cargoes. The general offices, shops, hospital, &c., are located at Rincon Antonio, at the entrance to the Chivela Pass, where the temperature is cool and healthful conditions prevail. At Santa Lucrecia, 109 m. from Salina Cruz, connexion is made with the Vera Cruz & Pacific railway (a government line), 213 m. to Cordova and 311 m. to Mexico city.

TEHUELCHE, Chuelche, or Huilliche ("Southern People"), the generic name given by the whites of Argentina to the Indian tribes of Patagonia (*q.v.*).

TEIGNMOUTH, JOHN SHORE, 1st Baron (1751–1834), governor-general of India, was born on the 8th of October 1751, the son of Thomas Shore, a supercargo in the service of the

East India Company. He was educated at Harrow, and went out to India as a writer in the Bengal Civil Service in 1769. He became a member of the Supreme Council (1787–89), in which capacity he assisted Lord Cornwallis in introducing many reforms, but did not approve his permanent settlement of Bengal. On the retirement of Cornwallis, he was appointed governor-general (1793–98), adopting a policy of non-interference, but deposed Wazir Ali, for whom he substituted Saadat Ali as nawab of Oudh. His term of office was also signalized by a mutiny of the officers of the Indian army, which he met with concessions. He was created a baronet in 1792, and Baron Teignmouth in the peerage of Ireland in 1798. On his retirement from India he was appointed member of the board of control (1807–28), and was for many years president of the British and Foreign Bible Society. He died on the 14th of February 1834.

See *Memoirs of Lord Teignmouth*, by his son (1843).

TEIGNMOUTH, a seaport and market town in the Ashburton parliamentary division of Devonshire, England, at the mouth of the river Teign, on the English Channel, 15 m. S. by E. of Exeter, by the Great Western railway. Pop. of urban district (1901) 8636. Two parishes, East and West Teignmouth, form the town. It lies partly on a peninsula between the river and the sea, partly on the wooded uplands which enclose the valley and rise gradually to the high moors beneath Heytor. The Den, or Dene, forms a promenade along the sea-front, with a small lighthouse and a pier. St Michael's church in East Teignmouth was rebuilt in 1824 in Decorated style, but retains a Norman doorway and other ancient portions; of St James', in West Teignmouth, the south porch and tower are Norman. There are a theological college for Redemptorists, and a Benedictine convent, dedicated to St Scholastica. The entrance to the harbour has been improved by dredging, and the two quays accommodate vessels drawing 13 ft. at neap tides. Pipeclay and china clay, from Kingsteignton, are shipped for the Staffordshire potteries, while coal and general goods are imported. Pilchard, herrings, whiting and mackerel are taken, and salmon in the Teign. Malting, brewing and boatbuilding are also carried on. East Teignmouth was formerly called Teignmouth Regis, and West Teignmouth, Teignmouth Episcopi.

Teignmouth (*Teinemue*, *Tengemue*) possessed a church of St Michael as early as 1044, when what is now East Teignmouth was granted by Edward the Confessor to Leofric, bishop of Exeter, and an allusion to salterers in the same grant proves the existence of the salt industry at that date. Teignmouth is not mentioned in the Domesday Survey, but in 1276 what is now West Teignmouth appears as a mesne borough held by the dean and chapter of Exeter; what is now East Teignmouth continuing with the bishop, who was accused in that year of holding in his manor a market which should be held in the borough. The bishop's manor was alienated in 1550 to Sir Andrew Dudley, but West Teignmouth remained with the dean and chapter until early in the 19th century. In the middle ages Teignmouth was a flourishing port, able to furnish 7 ships and 120 mariners to the Calais expedition of 1347, and depending chiefly on the fishing and salt industries. In the early part of the 17th century the town had fallen into decay, but it speedily recovered, and in 1744 could contribute twenty vessels to the Newfoundland shipping trade. The borough was never represented in parliament, nor incorporated by charter. The Saturday market, which was held up to the 19th century, is mentioned in 1220, and was confirmed by royal charter in 1253, together with a fair at Michaelmas. Teignmouth was burned by French pirates in 1340, and was again devastated by the French on the 26th of June 1690.

See *Victoria County History, Devonshire; The Teignmouth Guide and Complete Handbook to the Town and Neighbourhood* (Teignmouth, 1875).

TEIRESIAS, in Greek legend, a famous Theban seer, son of Eueres and Chariclo. He was a descendant of Udaeus, one of the men who had sprung up from the serpent's teeth sown by Cadmus. He was blind from his seventh year, for which various causes were alleged. Some said that the gods had blinded him because he had revealed to men what they ought not to know. Others said that Athena (or Artemis) blinded him because he had seen her naked in the bath; when his mother prayed Athena to restore his sight, the goddess, being unable to do so, purged his ears so that he could understand the speech of birds, and gave him a staff wherewith to guide his steps (Apollodorus iii. 6). According to Sostratus, author of an elegiac poem called *Teiresias*, he was originally a girl, but had been changed into a boy by Apollo at the age of seven; after undergoing several more transformations from one sex to the other, she (for the final sex was feminine) was turned into a mouse and her lover Arachnus into a weasel (Eustathius on *Odyssey*, p. 1665). Teiresias' grave was at the Tilphusian spring; but there was a cenotaph of him at Thebes, and also in later times his "observatory," or place for watching for omens from birds, was pointed out (Pausanias ix 16; Sophocles, *Antigone*, 999). He had an oracle at Orchomenus, but during a plague it became silent and remained so in Plutarch's time (*De Defectu Oraculorum*, 44). According to Homer (*Od.* x. 492, xi. 90), Teiresias was the only person in the world of the dead whom Proserpine allowed to retain his memory and intellect unimpaired, and Circe sends Odysseus to consult him concerning his return home. He figured in the great paintings by Polygnotus in the Lesche at Delphi.

TEISSERENC DE BORT, PIERRE EDMOND (1814–1892), French writer and politician, was born at Châteauroux on the 17th of September 1814, and entered the civil service after the completion of his education at the École Polytechnique. He was a railway expert, becoming secretary-general of the Railway Commission established in 1842, government commissioner to the authorized railway companies, administrator of the Lyons-Mediterranean railway, and commissioner to examine foreign railways. In 1846 he was returned to the Chamber of Deputies for Hérault, but the revolution of 1848 drove him into private life, from which he only emerged after the downfall of the Empire, when in February 1871 he was returned to the National Assembly. He supported the government of Thiers and was minister of agriculture and commerce in 1872–73. He sat in the Left Centre, and steadily supported republican principles. He entered the Senate in 1876, and was minister of agriculture in the Dufaure-Ricard cabinet of that year, retaining his portfolio in the Jules Simon ministry which fell on the 16th of May 1877. In 1878, when he joined the new Dufaure cabinet, he opened the Paris exhibition of agriculture and manufactures, the original suggestion of which had been made by him during his 1876 ministry. In 1879 he was sent as ambassador to Vienna, whence he was next year recalled on the score of health. Two years later he re-entered the Senate, where he did good service to the cause of "Republican Defence" during the Boulangist agitation. He died in Paris on the 29th of July 1892. His works consist of discussions of railway policy from the technical and economic side.

TELAMONES (Gr. τελάμων, supporter, from τλῆναι, to bear), in architecture the term used by the Romans as equivalent to Atlantes (the Greek term) for male figures employed to carry architraves and cornices. The best-known examples are those in the tepidarium of the baths of Pompeii, which consist of small figures in terra-cotta, 2 ft. high, placed between niches and carrying a cornice.

TELANG, KASHINATH TRIMBAK (1850–1893), Indian judge and oriental scholar, was born at Bombay on the 30th of August 1850. By profession an advocate of the high court, he also took a vigorous share in literary, social, municipal and political work, as well as in the affairs of the university of Bombay, over which he presided as vice-chancellor from 1892 till his death. At the age of five Telang was sent to the Amarchaud Wadi vernacular school, and in 1859 entered the high school in Bombay which bears the name of Mountstuart Elphinstone. Here he came under the influence of Narayan Mahadev Purmanand, a teacher of fine intellect and force of character, afterwards one of Telang's most intimate friends.

From this school he passed to the Elphinstone College, of which he became a fellow, and after taking the degree of M.A. and LL.B., decided to follow the example of Bal Mangesh Wagle, the first Indian admitted by the judges to practise on the original side of the high court, a position more like the status of a barrister than a vakil or pleader. He passed the examination and was enrolled in 1872. His learning and other gifts soon brought him an extensive practice. He had complete command of the English language, and his intimacy with Sanskrit enabled him to study and quote the Hindu law-books with an ease not readily attained by European counsel. Telang, finding his career assured, declined an offer of official employment. But in 1889 he accepted a seat on the high court bench, where his judgments are recognized as authoritative, especially on the Hindu law. He was syndic of the university from 1881, and vice-chancellor from 1892 till his death. In that year also he was elected president of the local branch of the Royal Asiatic Society. These two offices had never been held by a native of India before. The decoration of C.I.E. conferred on him in 1882 was a recognition of his services as a member of a mixed commission appointed by the government to deal with the educational system of the whole of India. He was nominated to the local legislative council in 1884, but declined a similar position on the viceroy's council. Along with P.M. Metha, he was the originator of the Bombay Presidency Association. When a student he had won the Bhugwandas scholarship in Sanskrit, and in this language his later studies were profound. His translation of the *Bhagwadgita* into English prose and verse is a standard work; and he criticized Professor Weber's hypothesis that the story of the *Ramayana* was influenced by the Homeric epics. While devoted to the sacred classics of the Hindus, Telang did not neglect his own vernacular, Mahratti literature being enriched by his translation of Lessing's *Nathan the Wise*, and an essay on *Social Compromise*. He died at Bombay on the 1st of September 1893.

TELAV, a town of Russian Transcaucasia, in the government of Tiflis, 63 m. N.E. of the town of Tiflis, on the river Alazan and at an altitude of 2420 ft. Pop. (1897) 11,810, chiefly Armenians (9000) and Georgians (2000). Telav is a very old town, founded in 893, and until 1797 it was the capital of Kakhetia, and has ruins of old forts. In the neighbourhood are the Ikaltoi monastery (6th century), the Shuanty monastery (16th century), and the originally 10th century Alaverdi church, visited by many pilgrims. Wine is exported.

TELEGONY (Gr. τῆλε, far, and γόνος, offspring), the name now given to the hypothesis that offspring sometimes inherit characters from a previous mate of their dam. Until recent years the supposed inheritance of characters acquired by a dam from one or more of her former mates was usually designated by breeders "throwing back"; by physiologists, "infection of the germ," or simply "infection." The doctrine of "infection," like the somewhat allied doctrine of "maternal impressions," seems to be alike ancient and widespread. Evidence of the antiquity of the belief in "maternal impressions" we have in Jacob placing peeled rods before Laban's cattle to induce them to bring forth "ring-straked speckled and spotted" offspring; evidence of the antiquity of the "infection" doctrine we have, according to some writers, in the practice amongst the Israelites of requiring the childless widow to marry her deceased husband's brother, that he might "raise up seed to his brother." Whatever may have been the views of stockowners in the remote past, it is certain that during the middle ages the belief in "infection" was common amongst breeders, and that during the last two centuries it met with the general approval of naturalists, English breeders being especially satisfied of the fact that the offspring frequently inherited some of their characters from a former mate of the dam, while both English and Continental naturalists (apparently without putting the assertions of breeders to the test of experiment) accounted for the "throwing back" by saying the germ cells of the dam had been directly or indirectly "infected" by a former mate. It is noteworthy that L. Agassiz, C. Darwin, W. B. Carpenter, and G. J. Romanes were all more or less firm believers in the doctrine of infection, and that a few years ago, with the exception of Professor A. Weismann, all the leading biologists had either subscribed to the telegony doctrine or admitted that "infection of the germ" was well within the bounds of possibilities. Even Professor Weismann did not deny the possibility of the offspring throwing back to a previous mate. The widespread belief, he admitted, "may be justifiable and founded on fact," but he was careful to add that "only the confirmation of the tradition by methodical investigation, in this case by experiment, could raise telegony to the rank of a fact." In assuming this attitude Professor Weismann decidedly differed from Herbert Spencer, who some years ago mentioned that he had evidence "enough to prove the fact of a previous sire asserting his influence on a subsequent progeny."

The importance of determining whether there is such a thing as telegony is sufficiently evident. If a mare or other female animal is liable to be "infected" by her first or by subsequent mates, telegony will rank as a cause of variation, and breeders will be justified in believing (1) that pure-bred females are liable to be "corrupted" when mated with sires of a different breed; and (2) that inferior or cross-bred females, if first mated with a high-class sire, will thereafter produce superior offspring, however inferior or cross-bred her subsequent mates. If, on the other hand, "infection of the germ" is impossible, telegony will not count as a factor in variation, and breeders will no longer be either justified in regarding mares and other female animals as liable to be "corrupted" by ill-assorted unions, or benefited by first having offspring to a high-class, or it may be more vigorous, mate. Though, according to breeders, evidence of telegony has been found in nearly all the different kinds of domestic mammals and birds, most stress has been laid on instances of "infection" in the horse and dog families.

Telegony in the Horse Family.—Beecher at the end of the 17th century pointed out that "when a mare has had a mule by an ass and afterwards a foal by a horse, there are evident marks on the foal of the mother having retained some ideas of her former paramour, the ass." That mares used in mule breeding are liable to be infected is still widely believed, but irrefragable evidence of the influence of the ass persisting, as Agassiz assumed, is conspicuous by its absence. Darwin says, "It is worth notice that farmers in south Brazil . . . are convinced that mares which have once borne mules when subsequently put to horses are extremely liable to produce colts striped like a mule" (*Animals and Plants*, vol. i. p. 436). Baron de Parana, on the other hand, says, "I have many relatives and friends who have large establishments for the rearing of mules, where they obtain from 400 to 1000 mules in a year. In all these establishments, after two or three crossings of the mare and ass, the breeders cause the mare to be put to a horse; yet a pure-bred foal has never been produced resembling either an ass or a mule."

The prevalence of the belief in telegony at the present day is largely due to a case of supposed infection reported to the Royal Society in 1820 by Lord Morton. A chestnut mare, after having a hybrid by a quagga, produced to a black Arabian horse three foals showing a number of stripes—in one more stripes were present than in the quagga hybrid. The more, however, the case so intimately associated with the name of Lord Morton is considered, the less convincing is the evidence it affords in favour of "infection." Stripes are frequently seen in high-caste Arab horses, and cross-bred colts out of Arab mares sometimes present far more distinct bars across the legs and other zebra-like markings than characterized the subsequent offspring of Lord Morton's seven-eighths Arabian mare. In the absence of control experiments there is therefore no reason for assuming Lord Morton's chestnut mare would have produced less striped offspring had she been mated with the black Arabian before giving birth to a quagga hybrid. To account for the stripes on the subsequent foals, it is only necessary (now that the principles of cross-breeding are better understood) to assume that in the cross-bred chestnut mare there lay latent the characteristics of the Kattiawar or other

Indian breeds, in which stripes commonly occur. Darwin and others having regarded Lord Morton's mare as affording very strong evidence in support of the infection hypothesis, it was considered some years ago desirable to repeat Lord Morton's experiment as accurately as possible. The quagga having become extinct, a number of mares were put to a richly striped Burchell zebra, and subsequently bred with Arab, thoroughbred and cross-bred sires. Other mares were used for control experiments. Thirty mares put to a Burchell zebra produced seventeen hybrids, and subsequently twenty pure-bred foals. The mares used for control experiments produced ten pure-bred foals. Unlike Lord Morton's quagga hybrids, all the zebra hybrids were richly, and sometimes very distinctly, striped, some of them having far more stripes than their zebra parent. Of the subsequent foals, three out of Highland mares presented indistinct markings at birth. But as equally distinct markings occurred on two pure-bred Highland foals out of mares which had never seen a zebra, it was impossible to ascribe the stripes on the foals born after zebra hybrids to infection of their respective dams. Further, the subsequent foals afforded no evidence of infection, either in the mane, tail, hoofs or disposition. Of the pure-bred foals, *i.e.* the foals by pure-bred sires out of mares which had never been mated with a zebra, two were striped at birth and one acquired stripes later—they were revealed as the foal's coat was shed. Moreover, while the faint markings on the foals born after hybrids completely disappeared with the foals' coat, the stripes on the three pure-bred colts persisted. One of the permanently striped colts, a bay, was out of a black Shetland mare by a black Shetland sire, one was by a dun Norwegian pony out of a roan-coloured Arab mare, while the third was by a Norwegian pony out of a half-bred bay Arab mare. It has been asserted by believers in telegony that evidence of infection may appear in the second though not present in the first generation. By way of testing this assumption, a bay filly, the half-sister of a richly striped hybrid, was put to a cross-bred Highland pony, and a Highland mare, while nursing her hybrid foal, was put to a colt the half-brother of a hybrid. The result was two fillies which in no single point either suggest a zebra or a zebra hybrid. Similar results having been obtained with horses and asses, there is no escape from the conclusion that the telegony tradition is not confirmed by such methodical investigations as were suggested some years ago by Professor Weismann (see Cossar Ewart, *The Penycuik Experiments*, 1899).

Telegony in Dogs.—Breeders of dogs are, if possible, more thoroughly convinced of the fact of telegony than breeders of horses. Nevertheless, Sir Everett Millais, a recognized authority, has boldly asserted that after nearly thirty years' experience, during which he made all sorts of experiments, he had never seen a case of telegony. Recent experiments support Millais's conclusion. Two of the purest breeds at the present day are the Scottish deerhound and the Dalmatian (spotted carriage-dog), A deerhound after having seven pups to a Dalmatian was put to a dog of her own breed. The result was five pups, which have grown into handsome hounds without the remotest suggestion of the previous Dalmatian mate of their dam. A similar result was obtained with a deerhound first mated with a retriever. Many accidental experiments on telegony are made annually with dogs. Two such experiments may be mentioned. A black-brindled Scottish terrier belonging to a famous breed had first a litter of pups to a curly-haired liver-and-white cocker-spaniel. The pups were spaniel-like in build, and of a brown-and-white colour. Subsequently this terrier had pups to a black-brindled terrier. All the pure-bred pups were typical terriers, and evidence of their dam having escaped infection is the fact that three of them proved noted prize-winners. The subject of the second undesigned experiment was a wire-haired fox-terrier. In this case the first sire was a white Pomeranian, the second a cross-bred Irish terrier. Having had ample opportunity of being "corrupted," the fox-terrier was mated with a prize dog of her own strain. The result was three pups, all in make and markings pure terriers, and one of the three was regarded as an unusually good specimen of the breed.

Experiments with cats, rabbits, mice, with sheep and cattle, with fowls and pigeons, like the experiments with horses and dogs, fail to afford any evidence that offspring inherit any of their characters from previous mates of the dam; *i.e.* they entirely fail to prove that a female animal is liable to be so influenced by her first mate that, however subsequently mated, the offspring will either in structure or disposition give some hint of the previous mate. In considering telegony it should perhaps be mentioned that some breeders not only believe the dam is liable to be "infected" by the sire, but also that the sire may acquire some of the characteristics of his mates. This belief seems to be especially prevalent amongst breeders of cattle; but how, for example, a long-horned Highland bull, used for crossing with black hornless Galloway cows, could subsequently get Galloway-like calves out of pure Highland heifers it is impossible to imagine.

In conclusion, it may be pointed out that it was only natural for breeders and physiologists in bygone days to account for some of their results by the "infection" hypothesis. Even now we know surprisingly little about the causes of variation, and not many years ago it was frequently asserted that there was no such thing as reversion or throwing back to an ancestor. But even were the laws of heredity and variation better understood, the fact remains that we know little of the origin of the majority of our domestic animals. On the other hand, from the experiments of Mendel and others, we now know that cross-bred animals and plants may present all the characters of one of their pure-bred parents, and we also know that the offspring of what are regarded as pure-bred parents sometimes revert to remote, it may be quite different, ancestors. The better we understand the laws of heredity and variation, and the more we learn of the history of the germ cells, the less need will there be to seek for explanations from telegony and other like doctrines. (J. C. E.)

TELEGRAPH (Gr. τῆλε, far, and γράφειν, to write), the name given to an apparatus for the transmission of intelligence to a distance. Etymologically the word implies that the messages are written, but its earliest use was of appliances that depended on visual signals, such as the semaphore or optical telegraph of Claude Chappe. The word is still sometimes employed in this sense, as of the ship's telegraph, by means of which orders are mechanically transmitted from the navigating bridge to the engine room, but when used without qualification it usually denotes telegraphic apparatus worked by electricity, whether the signals that express the words of the message are visual, auditory or written.

Land and Submarine Telegraphy will be considered in Part I., with a section on the commercial aspects. In Part II. Wireless Telegraphy is dealt with.

Part I.—Land and Submarine Telegraphy

Historical Sketch.—Although the history of practical electric telegraphy does not date much further back than the middle of the 19th century, the idea of using electricity for telegraphic purposes is much older. It was suggested again and again as each new discovery in electricity and magnetism seemed to render it more feasible. Thus the discovery of Stephen Gray and of Granville Wheeler that the electrical influence of a charged Leyden jar may be conveyed to a distance by means of an insulated wire gave rise to various proposals, of which perhaps the earliest was that in an anonymous letter[1] to the *Scots Magazine* (vol. xv. p. 73, 1753), in which the use of as many insulated conductors as there are letters in the alphabet was suggested. Each wire was to be used for the transmission of one letter only, and the message was to be sent by charging the proper wires in succession, and received by observing the

[1] From correspondence found among Sir David Brewster's papers after his death it seems highly probable that the writer of this letter, which was signed "C. M.," was Charles Morrison, a surgeon and a native of Greenock, but at that time resident in Renfrew.

movements of small pieces of paper marked with the letters of the alphabet and placed under the ends of the wires. A very interesting modification was also proposed in the same letter, viz. to attach to the end of each wire a small light ball which when charged would be attracted towards an adjacent bell and strike it. Some twenty years later G. L. Le Sage proposed a similar method, in which each conductor was to be attached to a pith ball electroscope. An important advance on this was proposed in 1797 by Lomond,[1] who used only one line of wire and an alphabet of motions. Besides these we have in the same period the spark telegraph of Reiser, of Don Silva, and of Cavallo, the pith ball telegraph of Francis Ronalds (a model of which is in the collection of telegraph apparatus in the Victoria and Albert Museum), and several others.

Next came the discovery of Galvani and of Volta, and as a consequence a fresh set of proposals, in which voltaic electricity was to be used. The discovery by Nicholson and Carlisle of the decomposition of water, and the subsequent researches of Sir H. Davy on the decomposition of the solutions of salts by the voltaic current were turned to account in the water voltameter telegraph of Sömmering and the modification of it proposed by Schweigger, and in a similar method proposed by Coxe, in which a solution of salts was substituted for water. Then came the discovery by G. C. Romagnosi and by H. C. Oersted, of the action of the galvanic current on a magnet. The application of this to telegraphic purposes was suggested by Laplace and taken up by Ampere, and afterwards by Triboaillet and by Schilling, whose work forms the foundation of much of modern telegraphy. Faraday's discovery of the induced current produced by passing a magnet through a helix of wire forming part of a closed circuit was laid hold of in the telegraph of Gauss and Weber, and this application was at the request of Gauss taken up by Steinheil, who brought it to considerable perfection. Steinheil communicated to the Göttingen Academy of Sciences in September 1838 an account of his telegraph, which had been constructed about the middle of the preceding year. The currents were produced by a magneto-electric machine resembling that of Clarke. The receiving apparatus consisted of a multiplier, in the centre of which were pivoted one or two magnetic needles, which either indicated the message by the movement of an index or by striking two bells of different tone, or recorded it by making ink dots on a ribbon of paper.

Steinheil appears to have been anticipated in the matter of a recording telegraph by Morse of America, who in 1835 constructed a rude working model of an instrument; this within a few years was so perfected that with some modification in detail it has been largely used ever since (see below). In 1836 Cooke, to whom the idea appears to have been suggested by Schilling's method, invented a telegraph in which an alphabet was worked out by the single and combined movement of three needles. Subsequently, in conjunction with Wheatstone, he introduced another form, in which five vertical index needles, each worked by a separate multiplier, were made to point out the letters on a dial. Two needles (for some letters, one only) were acted upon at the same time, and the letter at the point of intersection of the direction of the indexes was read. This telegraph required six wires, and was shortly afterwards displaced by the single-needle system, still to a large extent used on railway and other less important circuits. The single-needle instrument is a vertical needle galvanoscope worked by a battery and reversing handle, or two "tapper" keys, the motions to right and left of one end of the index corresponding to the dashes and dots of the Morse alphabet. To increase the speed of working, two single-needle instruments were sometimes used (double-needle telegraph). This system required two line wires, and, although a remarkably serviceable apparatus and in use for many years, is no longer employed. Similar instruments to the single and double needle apparatus of Cooke and Wheatstone were about the same time invented by the Rev. H. Highton and his brother Edward Highton, and were used for a considerable time on some of the railway lines in England. Another series of instruments, introduced by Cooke and Wheatstone in 1840, and generally known as "Wheatstone's step-by-step letter-showing" or "ABC instruments," were worked out with great ingenuity of detail by Wheatstone in Great Britain and by Bréguet and others in France. The Wheatstone instrument in the form devised by Stroh is still largely used in the British Postal Telegraph Department. Wheatstone also described and to some extent worked out an interesting modification of his step-by-step instrument, the object of which was to produce a letter-printing telegraph. But it never came into use; some years later, however, an instrument embodying the same principle, although differing greatly in mechanical detail, was brought into use by Royal E. House, of Vermont, U.S., and was very successfully worked on some of the American telegraph lines till 1860, after which it was gradually displaced by other forms. Various modifications of the instrument are still employed for stock telegraph purposes.

[1] See Arthur Young, *Travels in France*, p. 3.

Construction of Telegraph Circuits.—The first requisite for electro-telegraphic communication between two localities is an insulated conductor extending from one to the other. This, with proper apparatus for originating electric currents at one end and for discovering the effects produced by them at the other end, constitutes an electric telegraph. Faraday's term "electrode," literally "a way (ὁδός) for electricity to travel along," might be well applied to designate the insulated conductor along which the electric messenger is despatched. It is, however, more commonly and familiarly called "the wire" or "the line." The apparatus for generating the electric action at one end is commonly called the *transmitting apparatus* or *instrument*, or the *sending apparatus* or *instrument*, or sometimes simply the *transmitter* or *sender*. The apparatus used at the other end of the line to render the effects of this action perceptible to the eye or ear, is called the *receiving apparatus* or *instrument*.

Overground lines.

In the aerial or overground system of land telegraphs the use of copper wire has become very general. The advantage of the high conducting power which copper possesses is of especial value in moist climates (like that of the United Kingdom), since the effect of leakage over the surface of the damp insulators is much less noticeable when the conducting power of the wire is high than when it is low, especially when the line is a long one. Copper is not yet universally employed, price being the governing factor in its employment; moreover, the conducting quality of the iron used for telegraphic purposes has of late years been very greatly improved.

In the British Postal Telegraph system five sizes of iron wire are in general use, weighing respectively 200, 400, 450, 600 and 800 lb per statute mile, and having electrical resistances (at 60° F.) of 26·64, 13·32, 11·84, 8·88 and 6·66 standard ohms per statute mile respectively. The sizes of copper wire employed have weights of 100, 150, 200 and 400 lb per statute mile, and have electrical resistances (at 60° F.) of 8·782, 5·855, 4·391 and 2·195 standard ohms respectively. Copper wire weighing 600 and 800 lb per mile has also been used to some extent. The copper is "hard drawn," and has a breaking strain as high as 28 tons per sq. in.; the test strain required for the iron wire is about 22½ tons. The particular sizes and descriptions of wires used are dependent upon the character of the "circuits" the longer and more important circuits requiring the heavier wire.

The lines are carried on poles, at a sufficient height above the ground, by means of insulators. These vary in form, but essentially they consist of a stem of porcelain, coarse earthenware, glass or other non-conducting substance, protected by an overhanging roof or screen. The form in general use on the British postal lines is the "Cordeaux screw," but the "Varley double cup" is still employed, especially by the railway companies.

The latter form consists (fig. 1) of two distinct cups (*c*, C), which are moulded and fired separately, and afterwards cemented together. The double cup gives great security against loss of insulation due to cracks extending through the insulator, and also gives a high surface insulation. An iron bolt (*b*) cemented into the centre of the inner cup is used for fixing the insulator to the pole or bracket.

This form of insulator is still largely used and is a very serviceable pattern, though possessing the defect that the porcelain cup is not removable from the iron bolt on which it is mounted. The Cordeaux insulator (fig. 2) is made in one piece. A coarse screw-thread is formed in the upper part of the inner cup, and this screws on to the end of the iron bolt by which it is supported. Between a shoulder, *a*, in the iron bolt and a shoulder in the porcelain cup, *c*, is placed an indiarubber ring, which forms a yielding washer and enables the cup to be screwed firmly to the bolt, while preventing

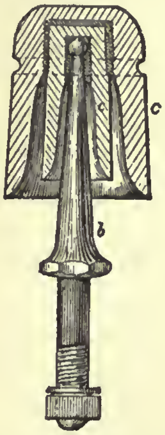

FIG. 1.—Varley's Double Cup Insulator, one-fourth full size.

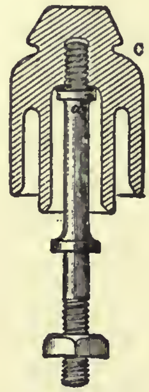

FIG. 2.—Cordeaux Insulator.

the abrasion of the porcelain against the iron. The advantage of the arrangement is that the cup can at any time be readily removed from the bolt. At the termination of a line a large insulator (fig. 3), mounted on a strong steel bolt having a broad base flange, is employed. Connexion is made into the office (or to the underground system, as is often the case) from the aerial wire by means of a copper conductor, insulated with gutta-percha, which passes through a "leading in" cup, whereby leakage is prevented between the wire and the pole. The insulators are planted on creosoted oak arms, $2\frac{1}{2}$ in. sq. and varying in length from 24 to 48 ins., the 24 and 33 in. arms taking two, and the 48 in. four, insulators. The

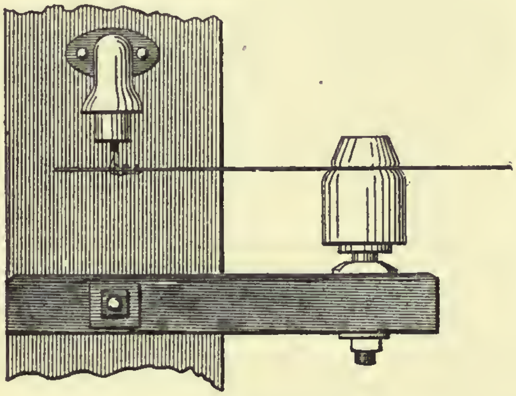

FIG. 3.—Terminal Insulator.

unequal lengths of the 24 and 33 in. arms are adopted for the purpose of allowing one wire to fall clear of that beneath it, in the case of an insulator breaking or the securing binder giving way. The poles are of red fir, creosoted, this method of preservation being the only one now used for this purpose in the United Kingdom. The number of poles varies from about 15 to 22 per m. of line; they are planted to a depth of from 2 to 4 ft. in the ground. For protection from lightning each pole has an "earth wire" running from the top, down to the base.

Underground lines.

Gutta-percha-covered copper wires were formerly largely used for the purpose of underground lines, the copper conductor weighing 40 ℔ per statute mile, and the gutta-percha covering 50 ℔ (90 ℔ total). The introduction of *paper* cables, *i.e.* copper wires insulated with carefully dried paper of a special quality, has practically entirely superseded the use of wires insulated with gutta-percha. The paper cables consist of a number of wires, each enveloped in a loose covering of well-dried paper, and loosely laid up together with a slight spiral "lay" in a bundle, the whole being enclosed in a stout lead pipe. It is essential that the paper covering be loose, so as to ensure that each wire is enclosed in a coating not of paper only, but also of air; the wires in fact are really insulated from each other by the dry air, the loose paper acting merely as a separator to prevent them from coming into contact. The great advantage of this air insulation is that the electrostatic capacity of the wires is low (about one-third of that which would be obtained with gutta-percha insulation), which is of the utmost importance for high-speed working or for long-distance telephonic communication. As many as 1200 wires are sometimes enclosed in one lead pipe.

Between London and Birmingham a paper cable 116 m long and consisting of 72 copper conductors, each weighing 150 ℔ per statute mile, was laid in 1900. The conductors are enclosed in a lead pipe, $2\frac{1}{4}$ in. in outside diameter and $\frac{1}{8}$ in. thick, which itself is enclosed in cast iron spigot-ended pipes, 3 in. in internal diameter, and buried 2 ft. below the surface of the roadway. At intervals of 2 m. "test pillars" are placed for the purpose of enabling possible faults to be accurately located. Each conductor has a resistance (at 60° F.) of 5·74 ohms per statute mile, and an average electrostatic capacity per mile between adjacent wires of 0·06 microfarad, or between wire and earth of 0·1 microfarad; the insulation resistance of each wire is about 5000 megohms per mile. The underground system of paper cables has been very largely extended. Cables between London, Glasgow, Edinburgh, Liverpool Leeds, Bristol, Exeter and other important towns have been laid. and eventually telegraphic communication between every important town in the United Kingdom will be rendered safe from interruptions caused by gales or snowstorms.

The one disadvantage of paper cables is the fact that any injury to the lead covering which allows moisture to penetrate causes telegraphic interruption to the whole of the enclosed wires, whereas if the wires are each individually coated with gutta-percha, the presence of moisture can only affect those wires whose covering is defective There is no reason for doubting, however, that, provided the lead covering remains intact, the paper insulation is imperishable; this is not the case with gutta-percha-covered wires.

Testing.

In order to maintain a system of telegraph lines in good working condition, daily tests are essential. In the British Postal Telegraph Department all the most important wires are tested every morning between 7.30 and 7.45 A.M., in sections of about 200 miles. The method adopted consists in looping the wires in pairs between two testing offices, A and B (fig. 4); a current is sent from a battery, E, through

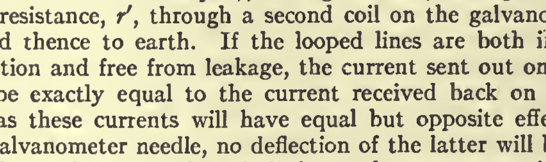

FIG. 4.—Method of testing Circuits.

one coil of a galvanometer, *g*, through a high resistance, *r*, through one of the wires, 1, and thence back from office B (at which the wires are looped), through wire 2, through another high resistance, *r'*, through a second coil on the galvanometer, *g*, and thence to earth. If the looped lines are both in good condition and free from leakage, the current sent out on line 1 will be exactly equal to the current received back on line 2; and as these currents will have equal but opposite effects on the galvanometer needle, no deflection of the latter will be produced. If, however, there is leakage, the current received on the galvanometer will be less than the current sent out, and the result will be a deflection of the needle proportional to the amount of leakage.

The galvanometer being so adjusted that a current of definite strength through one of the coils gives a definite deflection of the needle, the amount of leakage expressed in terms of the insulation resistance of the wires is given by the formula

$$\text{Total insulation resistance of looped lines} = \tfrac{1}{2}R(D/d - \tfrac{1}{2});$$

in which R is the total resistance of the looped wires, including the resistance of the two coils of the galvanometer, of the battery, and of the two resistance coils *r* and *r'* (inserted for the purpose of causing the leakage on the lines to have a maximum effect on the galvanometer deflections). In practice the resistances *r*, *r'* are of 10,000 ohms each. The deflection observed on the galvanometer when the lines are leaky is d, while D is the deflection obtained through *one* coil of the galvanometer with all the other resistances in circuit; and assuming that no leakage exists on the lines, this deflection is calculated from the "constant" of the instrument, *i.e.*, from the known deflection obtained with a definite current. For the purpose of avoiding calculation, tables are provided showing the values of the total insulation according to the formula, corresponding to various values of d. If the insulation per mile, *i.e.*, the total insulation multiplied by the mileage of the wire loop, is found to be less than 200,000 ohms, the wire is considered to be faulty. The climatic conditions in the British Islands are such that it is not possible to maintain, in unfavourable weather, a higher standard than that named, which is the insulation obtained when all the insulators are in perfect condition and only the normal leakage, due to moisture, is present.

Batteries.

There are three kinds of primary batteries in general use in the British Postal Telegraph Department, viz., the Daniell, the bichromate, and the Leclanché. The Daniell type consists of a teak trough divided into five cells by slate partitions coated with marine glue. Each cell contains a zinc plate, immersed in a solution of zinc sulphate, and also a porous chamber containing crystals of copper sulphate and a copper plate. The electromotive force of each cell is 1·07 volts and the resistance 3 ohms. The Fuller bichromate battery consists of an outer jar containing a solution of bichromate of potash and sulphuric acid, in which a plate of hard carbon is immersed; in the jar there is also a porous pot containing dilute sulphuric acid and a small quantity (2 oz.) of mercury, in which stands a stout zinc rod. The electromotive force of each cell is 2·14 volts, and the resistance 4 ohms. The Leclanché is of the ordinary type, and each cell has an electromotive force of 1·64 volts and a resistance of 3 to 5 ohms (according to the size of the complete cell, of which there are three sizes in use). Dry cells, *i.e.* cells containing no free liquid, but a chemical paste, are also largely employed; they have the advantage of great portability.

Accumulators.

Primary batteries have, in the case of all large offices, been displaced by accumulators. The force of the set of accumulator cells provided is such as to give sufficient power for the longest circuit to be worked, the shorter circuits being brought up approximately to a level, as regards resistance, by the insertion of resistance coils in the circuit of the transmitting apparatus of each shorter line. A spare set of accumulators is provided for every group of instruments in case of the failure of the working set. For working "double current," two sets of accumulators are provided, one set to send the positive and the other set the negative currents; that is to say, when, for example, a double current Morse key is pressed down it sends, say, a positive current from one set, but when it is allowed to rise to its normal position then a negative current is transmitted from the second set of accumulators. It is not possible to work double current from one set alone, as in this case, if one key of a group of instruments is up and another is down, the battery would be short-circuited and no current would flow to line. The size of the accumulators employed varies from a cell capable of an output of 8 ampere-hours, to a size giving 750 ampere-hours.

Submarine Cables.—A submarine cable (figs. 5–7), as usually manufactured, consists of a core a in the centre of which is a strand of copper wires varying in weight for different cables between 70 and 650 lb to the nautical mile. The stranded form was suggested by W. Thomson (Lord Kelvin) at a meeting of the Philosophical Society of Glasgow in 1854, because its greater flexibility renders it less likely to damage the insulating envelope during the manipulation of the cable. The central conductor is covered with several continuous coatings of gutta-percha, the total weight of which varies between 70 and 650 lb to the mile. Theoretically for a given outside diameter of core the greatest speed of signalling through a cable is obtained when the diameter of the conductor is ·606 $(1/\sqrt{\epsilon})$ the diameter of the core, but this ratio makes the thickness of the gutta-percha covering insufficient for mechanical strength. Owing to the high price of gutta-percha the tendency, of recent years, has been to approximate more closely to the theoretical dimensions, and a thickness of insulating material which formerly would have been considered quite insufficient is now very generally adopted with complete success. Of two transatlantic cables laid in 1894, the core of one consisted of 500 lb copper and 320 lb gutta-percha per mile, and that of the other of 650 lb copper and 400 lb gutta-percha; whereas for the similarly situated cable laid in 1866 the figures were 300 lb copper and 400 lb gutta-percha. The core is served with a thick coating of wet jute, yarn or hemp (h), forming a soft bed for the sheath, and, to secure immunity from the ravages of submarine boring animals, *e.g. Teredo navalis*, it has been found necessary, for depths not exceeding 300 fathoms, to protect the core with a thin layer of brass tape. The deep sea portion is sheathed with galvanized iron or steel wires (in the latter case offering a breaking strain of over 80 tons per sq. in., with an elongation of at least 5 per cent.), the separate wires being first covered with a firm coating of tape and Chatterton's compound (a

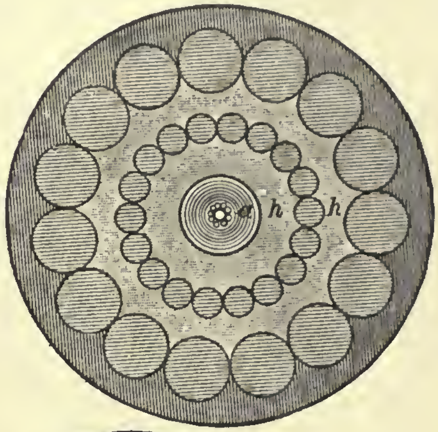

FIG. 5.

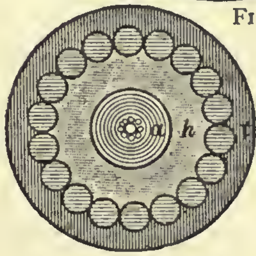

FIG. 6.

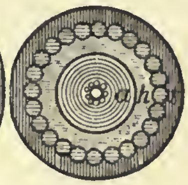

FIG. 7.

FIGS. 5–7.—Sections of three types of Submarine Cables, full size. Fig. 5.—Type of shore end. Fig. 6.—Intermediate type. Fig. 7.—Deep sea type.

mixture of gutta-percha, rosin and Stockholm tar). Sometimes the wires are covered with the compound alone, and the whole cable after being sheathed is finally covered with tarred tape. The weight of the iron sheath varies greatly according to the depth of the water, the nature of the sea bottom, the prevalence of currents, and so on. Fig. 5 shows the intermediate type again sheathed with a heavy armour to resist wear in the shallow water near shore. In many cases a still heavier type is used for the first mile or two from shore, and several intermediate types are often introduced, tapering gradually to the thin deep-water type.

The cost of the cable before laying depends on the dimensions of its core, the gutta-percha, which still forms the only trustworthy insulator known, constituting the principal item of the expense; for an Atlantic cable of the most approved construction the cost may be taken at £250 to £300 per nautical mile.

Manufacture.

In manufacturing a cable (fig. 8) the copper strand is passed through a vessel A containing melted Chatterton's compound, then through the cylinder C, in which a quantity of gutta-percha, purified by repeated washing in hot water, by mastication, and by filtering through wire-gauze filters, is kept warm by a steam-jacket. As the wire is pulled through, a coating of gutta-percha, the thickness of which is regulated by the die D, is pressed out of the cylinder by applying the requisite pressure to the piston P. The newly coated wire is passed through a long trough T, containing cold water, until it is sufficiently cold to allow it to be safely wound on a bobbin B′ This operation completed, the wire is wound from the bobbin B′ on to another, and at the same time carefully examined for air-holes or other flaws, all of which are eliminated. The coated wire is treated in the same way as the copper strand—the die D, or another of the same size, being placed at the back of the cylinder and a larger one substituted at the front. A second coating is then laid on, and after it passes through a similar process of examination a third coating is applied, and so on until the requisite number is completed. The finished core changes rapidly in its electric qualities at first, and is generally kept for a stated interval of time before being subjected to the specified tests. It is then placed in a tank of water and kept at a certain fixed temperature, usually 75° F., until it assumes approximately a constant electrical state. Its conductor and dielectric

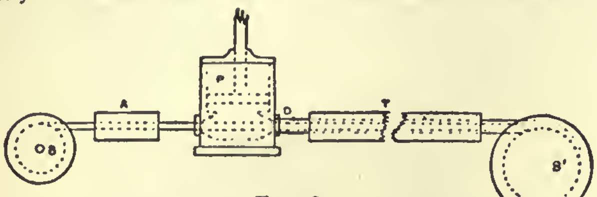

Fig. 8.

resistance and its electrostatic capacity are then measured. These tests are in some cases repeated at another temperature, say 50° F., for the purpose of obtaining at the same time greater certainty of the soundness of the core and the rate of variation of the conductor and dielectric resistances with temperature. The subjection of the core to a hydraulic pressure of four tons to the square inch and an electric pressure of 5000 volts from an alternating-current transformer has been adopted, by one manufacturer at least, to secure the detection of masked faults which might develop themselves after submergence. Should these tests prove satisfactory the core is served with jute yarn, coiled in water-tight tanks, and surrounded with salt water. The insulation is again tested, and if no fault is discovered the served core is passed through the sheathing machine, and the iron sheath and the outer covering are laid on. As the cable is sheathed it is stored in large water-tight tanks and kept at a nearly uniform temperature by means of water.

Laying.

When the cable is to be laid it is transferred to a cable ship, provided with water-tight tanks similar to those used in the factory for storing it. The tanks are nearly cylindrical in form and have a truncated cone fixed in the centre, as shown at C, fig. 9. The cable is carefully coiled into the tanks in horizontal flakes, each of which is begun at the outside of the tank

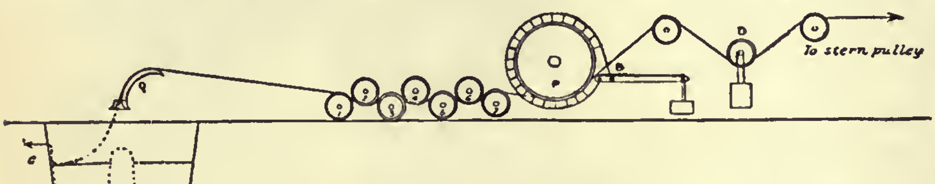

Fig. 9.—Diagram of Cable Tank and Paying-out Apparatus of Submarine Cable.

and coiled towards the centre. The different coils are prevented from adhering by a coating of whitewash, and the end of each nautical mile is carefully marked for future reference. After the cable has been again subjected to the proper electrical tests and found to be in perfect condition, the ship is taken to the place where the shore end is to be landed. A sufficient length of cable to reach the shore or the cable-house is paid overboard and coiled on a raft or rafts, or on the deck of a steam-launch, in order to be connected with the shore. The end is taken into the testing room in the cable-house and the conductor connected with the testing instruments, and, should the electrical tests continue satisfactory, the ship is put on the proper course and steams slowly ahead, paying out the cable over her stern. The cable must not be overstrained in the process of submersion, and must be paid out at the proper rate to give the requisite slack. This involves the introduction of machinery for measuring and controlling the speed at which it leaves the ship and for measuring the pull on the cable. The essential parts of this apparatus are shown in fig. 9. The lower end e of the cable in the tank T is taken to the testing room, so that continuous tests for electrical condition can be made. The upper end is passed over a guiding quadrant Q to a set of wheels or fixed quadrants 1, 2, 3, . . . then to the paying-out drum P, from it to the dynamometer D, and finally to the stern pulley, over which it passes into the sea. The wheels 1, 2, 3, . . . are so arranged that 2, 4, 6, . . . can be raised or lowered so as to give the cable less or more bend as it passes between them, while 1, 3, 5, . . . are furnished with brakes. The whole system provides the means of giving sufficient back-pull to the cable to make it grip the drum P, round which it passes several times to prevent slipping. On the same shaft with P is fixed a brake-wheel furnished with a powerful brake B, by the proper manipulation of which the speed of paying out is regulated, the pull on the cable being at the same time observed by means of D. The shaft of P can be readily put in gear with a powerful engine for the purpose of hauling back the cable should it be found necessary to do so. The length paid out and the rate of paying out are obtained approximately from the number of turns made by the drum P and its rate of turning. This is checked by the mile marks, the known position of the joints, &c., as they pass. The speed of the ship can be roughly estimated from the speed of the engines; it is more accurately obtained by one or other of the various forms of log, or it may be measured by paying out continuously a steel wire over a measuring wheel. The average speed is obtained very accurately from solar and stellar observations for the position of the ship. The difference between the speed of the ship and the rate of paying out gives the amount of slack. The amount of slack varies in different cases between 3 and 10 per cent., but some is always allowed, so that the cable may easily adapt itself to inequalities of the bottom and may be more readily lifted for repairs. But the mere paying out of sufficient slack is not a guarantee that the cable will always lie closely along the bottom or be free from spans. Whilst it is being paid out the portion between the surface of the water and the bottom of the sea lies along a straight line, the component of the weight at right angles to its length being supported by the frictional resistance to sinking in the water. If, then, the speed of the ship be v, the rate of paying out u, the angle of immersion i, the depth of the water h, the weight per unit length of the cable w, the pull on the cable at the surface P, and A, B constants, we have—

$$P = h\{w - (A/\sin i)f(u - v\cos i)\} \qquad (\alpha)$$

and

$$w\cos i = Bf(v\sin i) \qquad (\beta),$$

where f stand for "function." The factors $Af\ (u - v\cos i)$ and $Bf\ (v\sin i)$ give the frictional resistance to sinking, per unit length of the cable, in the direction of the length and transverse to the length respectively.[1] It is evident from equation (β) that the angle of immersion depends solely on the speed of the ship; hence in laying a cable on an irregular bottom it is of great importance that the speed should be sufficiently low. This may be illustrated very simply as follows: suppose $a\ a$ (fig. 10) to be the surface of the sea, $b\ c$ the bottom, and $c\ c$ the straight line made by the cable; then, if a hill H, which is at any part steeper than the inclination of the cable, is passed over, the cable touches it at some point t before it touches the part immediately below t, and if the friction between the cable and the ground is sufficient the cable will either break or be left in a long span ready to break at some future time. It is important to observe that the risk is in no way obviated by the increasing slack paid out, except in so far as the amount of sliding which the strength of the cable is able to produce at the points of contact with the ground may be thereby increased. The speed of the ship must therefore be so regulated that the angle of immersion is as great as the inclination of the steepest slope passed over. In ordinary circumstances the angle of immersion i varies between six and nine degrees.

The "slack indicator" of Messrs Siemens Brothers & Co. yields a continuous indication and record of the actual slack paid out. It consists of a long screw spindle, coupled by suitable gearing with the cable drum, and thus rotating at the speed of the outgoing cable; on this screw works a nut which forms the centre of a thin circular disk, the edge of which is pressed against the surface of a right circular cone, the line of contact, as the nut moves along the screw, being parallel to the axis of the latter. This cone is driven by gearing from the wire drum, so that it rotates at the speed of the outgoing wire, the direction of rotation being such as to cause the nut to travel towards the smaller end of the cone. If both

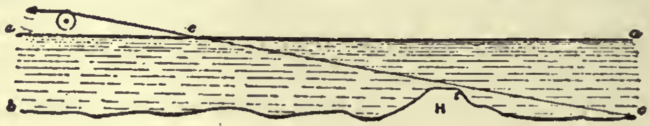

Fig. 10.

nut and screw are rotating at the same speed, the position of the former will remain fixed; and as the nut is driven by friction from the surface of the cone, this equality of speed will obtain only when the product of the diameter (d) of the cone at that position multiplied into its speed of rotation (n) equals the product of the diameter (a) of the disk multiplied into the speed of rotation (N) of the screw, or $N/n = d/a$, and thus the ratio of cable paid out to that of wire paid out is continuously given by a pointer controlled

[1] See Sir W. Thomson (Lord Kelvin) *Mathematical and Physical Papers*, vol. ii. p. 165.

by the disk, for any difference in speed between nut and screw will cause the nut to move along the screw until the diameter of the cone is reached which fulfils the above conditions for equality in speed. In fig. 11 the edge of the disk serves as the pointer and the scale gives the percentage of slack, or $(N-n)/n$. The wire being paid out without slack measures the actual distance and speed over the ground, and the engineer in charge is relieved of all anxiety in estimating the depth from the scattered soundings of the preliminary survey, or in calculating the retarding strain required to produce the specified slack, since the brakesman merely has to follow the indications of the instrument and regulate the strain so as to keep the pointer at the figure required—an easy task, seeing that the ratio of speed of wire and cable is not affected by the motion of the ship, whatever be the state of the sea, whereas the

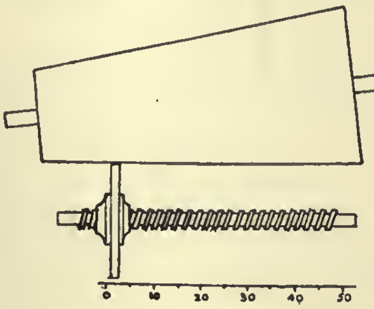

Fig. 11.—Slack Indicator.

strain will in heavy weather be varying 50 per cent. or more on each side of the mean value. Further, the preliminary survey over the proposed route, necessary for deciding the length and types of cable required, can afford merely an approximation to the depth in which the cable actually lies, since accidents of wind and weather, or lack of observations for determining the position, cause deviations, often of considerable importance, from the proposed route. From the continuous records of slack and strain combined with the weight of the cable it is a simple matter to calculate and plot the depths along the whole route of the cable as actually laid. Fig. 12, compiled from the actual records obtained during the laying of the Canso-Fayal section of the Commercial Cable Company's system, shows by the full line the actual strain recorded which secured the even distribution of 8 per cent. of slack, and by the dotted line the strain that would have been applied if the soundings taken during the preliminary survey had been the only source available, although the conditions of sea and weather favoured

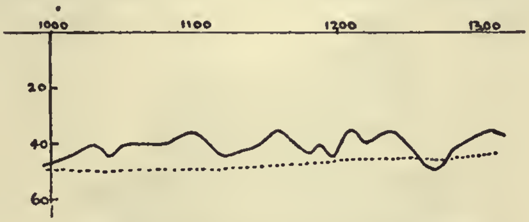

Fig. 12.—Records of Strain and Depths.

close adherence to the proposed route. The ordinates of the curve give the strain in cwts., and the abscissae the distance in miles measured from the Canso end; as the strain is proportional to the depth, 18 cwts. corresponding to 1000 fathoms, the black line represents to an exaggerated scale the contour of the sea bed.

Repairing.

Owing to the experience gained with many thousands of miles of cable in all depths and under varying conditions of weather and climate, the risk, and consequently the cost, of laying has been greatly reduced. But the cost of effecting a repair still remains a very uncertain quantity, success being dependent on quiet conditions of sea and weather. The *modus operandi* is briefly as follows: The position of the fracture is determined by electrical tests from both ends, with more or less accuracy, depending on the nature of the fracture, but with a probable error not exceeding a few miles. The steamer on reaching the given position lowers one, or perhaps two, mark buoys, mooring them by mushroom anchor, chain and rope. Using these buoys to guide the direction of tow, a grapnel, a species of five-pronged anchor, attached to a strong compound rope formed of strands of steel and manila, is lowered to the bottom and dragged at a slow speed, as it were ploughing a furrow in the sea bottom, in a line at right angles to the cable route, until the behaviour of the dynamometer shows that the cable is hooked. The ship is then stopped, and the cable gradually hove up towards the surface; but in deep water, unless it has been caught near a loose end, the cable will break on the grapnel before it reaches the surface, as the catenary strain on the bight will be greater than it will stand. Another buoy is put down marking this position, fixing at the same time the actual line of the cable. Grappling will be recommenced so as to hook the cable near enough to the end to allow of its being hove to the surface. When this has been done an electrical test is applied, and if the original fracture is between ship and shore the heaving in of cable will continue until the end comes on board. Another buoy is then lowered to mark this spot, and the cable on the other side of the fracture grappled for, brought to the surface, and, if communication is found perfect with the shore, buoyed with sufficient chain and rope attached to allow of the cable itself reaching the bottom. The ship now returns to the position of original attack, and by similar operations brings on board the end which secures communication with the other shore. The gap between the two ends has now to be closed by splicing on new cable and paying out until the buoyed end is reached, which is then hove up and brought on board. After the "final splice," as it is termed, between these ends has been made, the bight, made fast to a slip rope, is lowered overboard, the slip rope cut, and the cable allowed to sink by its own weight to its resting-place on the sea bed. The repair being thus completed, the various mark buoys are picked up, and the ship returns to her usual station.

The grappling of the cable and raising it to the surface from a depth of 2000 fathoms seldom occupy less than twenty-four hours, and since any extra strain due to the pitching of the vessel must be avoided, it is clear that the state of the sea and weather is the predominating factor in the time necessary for effecting the long series of operations which, in the most favourable circumstances, are required for a repair. In addition, the intervention of very heavy weather may mar all the work already accomplished, and require the whole series of operations to be undertaken *de novo*. As to cost, one transatlantic cable repair cost £75,000; the repair of the Aden-Bombay cable, broken in a depth of 1900 fathoms, was effected with the expenditure of 176 miles of new cable, and after a lapse of 251 days, 103 being spent in actual work, which for the remainder of the time was interrupted by the monsoon; a repair of the Lisbon-Porthcurnow cable, broken in the Bay of Biscay in 2700 fathoms, eleven years after the cable was laid, took 215 days, with an expenditure of 300 miles of cable. All interruptions are not so costly, for in shallower waters, with favourable conditions of weather, a repair may be only a matter of a few hours, and it is in such waters that the majority of breaks occur, but still a large reserve fund must be laid aside for this purpose. As an ordinary instance, it has been stated that the cost of repairing the Direct United States cable up to 1900 from its submergence in 1874 averaged £8000 per annum. Nearly all the cable companies possess their own steamers, of sufficient dimensions and specially equipped for making ordinary repairs; but for exceptional cases, where a considerable quantity of new cable may have to be inserted, it may be necessary to charter the services of one of the larger vessels owned by a cable-manufacturing company, at a certain sum per day, which may well reach £200 to £300. This fleet of cable ships now numbers over forty, ranging in size from vessels of 300 tons to 10,000 tons carrying capacity.

Life.

The life of a cable is usually considered to continue until it is no longer capable of being lifted for repair, but in some cases the duration and frequency of interruptions as affecting public convenience, with the loss of revenue and cost of repairs, must together decide the question of either making very extensive renewals or even abandoning the whole cable. The possibility of repair is affected by so many circumstances due to the environment of the cable, that not even an approximate term of years has yet been authoritatively fixed. It is a well-ascertained fact that the insulator, gutta-percha, is, when kept under water, practically imperishable, so that it is only the original strength of the sheathing wires and the deterioration allowable in them that have to be considered. Cables have frequently been picked up showing after many years of submergence no appreciable deterioration in this respect, while in other cases ends have been picked up which in the course of twelve years had been corroded to needle points, the result probably of metalliferous deposits in the locality. It is scarcely possible from the preliminary survey, with soundings several miles apart, to obtain more than a general idea as to the average depth along the route, while the nature of the constituents of the sea bed can only be revealed by a few small specimens brought up at isolated spots, though fortunately the globigerine ooze which covers the bottom at all the greater ocean depths forms an ideal bed for the cable. The experience gained in the earlier days of ocean telegraphy, from the failure and abandonment of nearly 50 per cent. of the deep-sea cables within the first twelve years, placed the probable life of a cable as low as fifteen years, but the weeding out of unserviceable types of construction, and the general improvement in materials, have by degrees extended that first estimate, until now the limit may be safely placed at not less than forty years. In depths beyond the reach of wave motion, and apart from suspension across a submarine gully, which will sooner or later result in a rupture of the cable, the most frequent cause of interruption is seismic or other shifting of the ocean bed, while in shallower waters and near the shore the dragging of anchors or fishing trawls has been mostly responsible. Since by international agreement the wilful damage of a cable has been constituted a criminal offence, and the cable companies have avoided crossing the fishing banks, or have adopted the wise policy of refunding the value of anchors lost on their cables, the number of such fractures has greatly diminished.

Instruments for Land Telegraphy.—At small country towns or villages, where the message traffic is light, the Wheatstone "A B C" instrument is used. In this apparatus electric currents are generated by turning a handle (placed in front of the instrument), which is geared, in the instruments of the most recent pattern, to a Siemens shuttle armature placed between the two arms of a powerful horseshoe permanent magnet. When one of a series of keys (each corresponding to a letter) arranged round a pointer is depressed, the motion of the pointer, which is geared to the shuttle armature, is arrested on coming opposite that particular key, and the transmission of the currents to line is stopped, though the armature itself can continue to rotate. The depression of a second key causes the first key to be raised. The currents actuate a ratchet-wheel mechanism at the receiving station, whereby the hand on a small dial is moved on letter by letter. A noticeable feature in the modern A B C indicator, as well as in all modern forms of telegraph instruments, is the adoption of "induced" magnets in the moving portion of the apparatus. A small permanent magnet is always liable to become demagnetized, or have its polarity reversed by the action of lightning. This liability is overcome by making such movable parts as require to be magnetic of soft iron, and magnetizing them by the inducing action of a strong permanent magnet. Although formerly in very extensive employment, this instrument is dropping out of use and the "sounder" (and in many cases the telephone) is being used in its place.

A B C instrument.

At offices where the work is heavier than can be dealt with by the A B C apparatus, the "Single Needle" instrument has been very largely employed; it has the advantage of slight liability to derangement, and of requiring very little adjustment. A fairly skilled operator can signal with it at the rate of 20 words per minute. The needle (in the modern pattern) is of soft iron, and is kept magnetized inductively by the action of two permanent steel magnets. The coils are wound with copper wire (covered with silk), 10 mils. in diameter, to a total resistance of 200 ohms. The actual current required to work the instrument is 3·3 milliamperes (equivalent approximately to the current given by 1 Daniell cell through 3300 ohms), but in practice a current of 10 milliamperes is allowed. A simple, but important, addition to enable the reading from the instrument to be effected by sound is shown in fig. 13; in this arrangement the needle strikes against small tubes formed of tin-plate. Although a most serviceable instrument and cheap as regards maintenance, the "single needle" has (except for railway telegraph purposes) been discarded in favour of the "sounder," to secure the advantage of using one general pattern of apparatus, as far as possible, and to avoid the necessity of two different types of instrument being learnt by the telegraphist.

Single needle instrument.

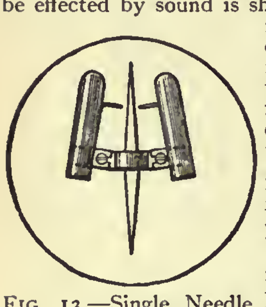

Fig. 13.—Single Needle with sounding arrangement.

The well-known code of signals (fig. 14) introduced by Morse is still employed in the United States and Canada, and the international code in vogue in Europe differs only slightly from it.

The instruments used for land telegraphs on this system are of two types—"sounders," which indicate by sound, and "recorders," which record the signals.

Recorders vary in details of construction, but all have the same object, namely, to record the intervals during which the current is applied to the line. In the earlier forms of instrument the record was made by embossing lines on a ribbon of paper by means of a sharp style fixed to one end of a lever, which carried at the other end the armature of an electromagnet. The form of Morse recorder almost universally used in Europe makes the record in ink, and hence is sometimes called the "ink-writer." This method has the advantage of distinctness, and so is less trying to the eyes of the operators. Although the "ink-writer" is still in use it is practically an obsolete instrument, and has been displaced by the "sounder."

Morse ink-writer.

Operators who used the recorder soon learned to read the message by the click of the armature against its stop, and as this left the hands and eyes free to write, reading by sound was usually preferred. Thus, when it is not necessary to keep a copy, a much simpler instrument may be employed and the message read by sound. The earliest successful form was "Bright's bell" sounder, which consisted of two bells of distinct tone or pitch, one of which was sounded when the current was sent in one direction and the other when it was reversed. This instrument was capable of giving very considerable speed, but it was more complicated than that now in use, which consists only of an electromagnet, with its armature lever arranged to stop against an anvil or screw in such a way as to give a distinct and somewhat loud sound. Dots and dashes are distinguished by the interval between the sounds of the instrument in precisely the same way as they are distinguished when reading from the recorder by sound. Fig. 15 shows the modern pattern of "sounder" as used by the British Post Office. The magnet is wound to a resistance of 40 ohms (or 900 ohms when worked from accumulators), and the instrument is worked with a current of 400 milliamperes (25 milliamperes with accumulators).

Sounder.

Fig. 14.—Morse Alphabets.

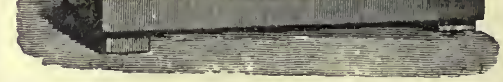

Fig. 15.—Modern "Sounder."

Methods of Working Land Circuits.—The arrangement on the "open-circuit" system for single-current working is shown in fig. 16, in which L_1 represents the line, G a galvanometer, used simply to show that the currents are going to line when the message is being transmitted, K the transmitting key, B the battery, I the receiving instrument, and E the earth-plate. The complete circuit is from the plate E through the instrument I, the key K, and the galvanoscope G to the line L_1, then through the corresponding instruments to the earth-plate E at the other end, and back through the earth to the plate E. The earth is always, except for some special reason, used as a return, because it offers little resistance and saves the expense and the risk of failure of the return wire. The earth-plate E ought to be buried in moist earth or in water. In towns the water and gas pipe systems form excellent earth

Open circuit, single-current system.

plates. It will be observed that the circuit is not in this case actually *open*; the meaning of the expression "open circuit" is "no battery to line." In normal circumstances the instruments at both ends are ready to receive, both ends of the line being to earth through the receiving instruments. A signal is sent by depressing the key K, and so changing the contact from *a* to *b*, and thus putting the battery to line. On circuits where the traffic is small it is usual to make one wire serve several stations. At an intermediate or wayside station W, a "switch" S, consisting of three blocks of brass fixed to an insulating base, is sometimes used (not in Great Britain). W may be made the terminal station of L_1 by inserting plug 3, and of L_2 by inserting plug 2, or the instruments may be cut out of circuit by inserting plug 1. In ordinary circumstances the messages from all stations are sent through the whole line, and thus the operator at any station may transmit, if the line is free, by manipulating his key.

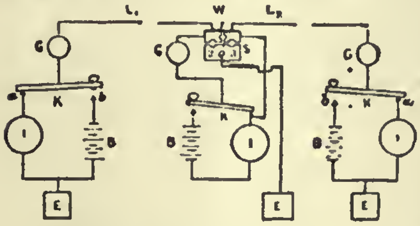

FIG. 16.—Open Circuit, Single-current System.

Closed-circuit system.

The connexions for single-current working on the "closed-circuit" system are shown in fig. 17. It differs from the open circuit in only requiring one battery (although, as in the figure, half of it is often placed at each end), in having the receiving instrument between the line and the key, and in having the battery continuously to the line. The battery is kept to the line by the bar *c*, which short-circuits the keys. When signals are to be sent from either station the operator turns the switch *c* out of contact with the stop *b*, and then operates precisely as in open circuit sending. This system is more expensive than the open-circuit system, as the battery is always at work; but it offers some advantages on circuits where there are a number of intermediate stations, as the circuit is under a constant electromotive force and has the same resistance no matter which station is sending or receiving. The arrangement at a wayside station is shown at W. When the circuit is long and contains a large number of stations, the sending battery is sometimes divided among them in order to give greater uniformity of current along the line. When only one battery is used the current at the distant end may be considerably affected by the leakage to earth along the line.

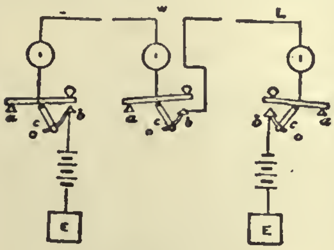

FIG. 17.—Closed Circuit, Single-current System.

Single-current relay working.

If long circuits were worked direct with ordinary instruments, high battery power would be required in order to send sufficient current to actuate the apparatus. In such cases it is usual to employ a local battery to produce the signals, and to close the local battery circuit by means of a circuit-closing apparatus called a *relay*, which is practically an electromagnetic key which has its lever attached to the armature of the magnet and which can be worked by a very weak current. The arrangement at a station worked by relay on the "single-current" system is shown in fig. 18, where L is the line wire, joined through the key K to one end of the coil of the relay magnet R, the other end of which is put to earth. When a current passes through R the armature A is attracted and the local circuit is closed through the armature at *b*. The local battery B_1 then sends a current through the instrument I and records the signal. In the form of relay indicated in the figure the armature is held against the stop *a* by a spring S.

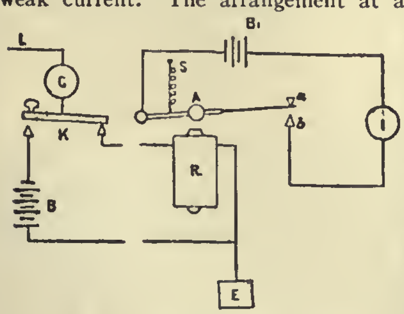

FIG. 18.—Single-current Relay Working.

Double-current system.

"Single-current" working by means of a non-polarized relay (fig. 18), although general in America, is not adopted in England. In the latter country, when such working is resorted to, a "polarized relay" (fig. 20) with a bias is used, but on all important lines worked by sounders the "double-current" system is employed. In this the tongue of the relay is kept over to the spacing side by means of a current flowing in one direction, but on the depression of the signalling key the current is reversed, moving the relay tongue over to the marking side.

Polarized relays.

The Siemens polarized relay, shown in fig. 19, consists of an armature *a*, pivoted at one end *h* in a slot at one end N of a permanent magnet *m*, the other pole *s* of which is fixed to the yoke *y* of a horse-shoe electromagnet M. The armature is placed between the poles of the electromagnet, and being magnetized by the magnet *m* it will oscillate to the right or left under the action of the poles of the electromagnet M according as the current passes through M in one direction or the other. This form of relay is largely used, but in Great Britain it has been entirely displaced by the form shown in fig. 20, which is the most modern pattern of relay used by the British Post Office, known as the "Post Office Standard Relay." In this instrument

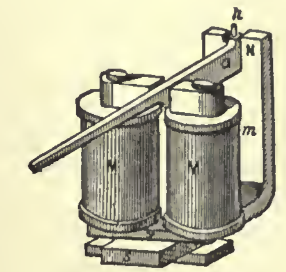

FIG. 19.—Siemens Polarized Relay.

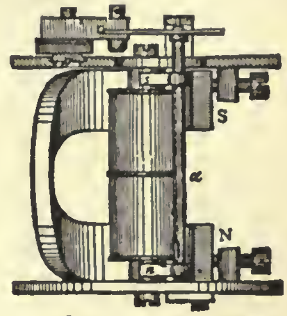

FIG. 20.—Post Office Standard Relay.

there are two soft iron tongues, *n*, *s*, fixed upon and at right angles to an axle *a*, which works on pivots at its ends. These tongues are magnetized by the inducing action of a strong horse-shoe permanent magnet, S N, which is made in a curved shape for the sake of compactness. The tongue plays between the poles of two straight electromagnets. The coils of the electromagnets are differentially wound with silk-covered wire, 4 mils (= ·004 inch) in diameter, to a total resistance of 400 ohms. This differential winding enables the instrument to be used for "duplex" working, but the connexions of the wires to the terminal screws are such that the relay can be used for ordinary single working. Although the relay is a "polarized" one, so that it can be used for "double-current" working, it is equally suitable for "single-current" purposes, as the tongue can be given a bias over to the "spacing" side, *i.e.* to

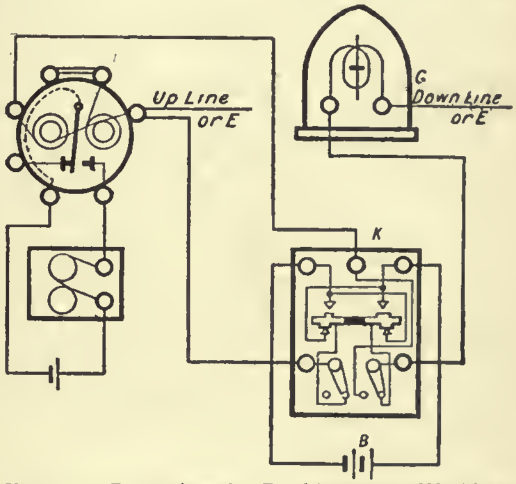

FIG. 21.—Connexions for Double-current Working.

the side on which no current passes through the local circuit. The standard relay will work single current with a current of 3 milliamperes, though in practice about 10 would be used. Worked double current—that is, with the tongue set neutral, having no bias either to the spacing or marking side—the relay will give good signals with 1½ milliampere of current, though in practice 10 milliamperes are provided. The lightness of the moving part enables great rapidity of action to be obtained, which for fast speed working is very essential. The relay tongue, being perfectly free to move, can be actuated by a comparatively weak current. Normally a switch attached to the key cuts the battery off, and connects the line direct through the receiving relay; this switch is turned to "send" when transmission commences, and is moved back to "receive" when it ceases: this movement is done quite mechanically by the telegraphist, and as it is practically never forgotten, automatic devices (which have often been suggested) to effect the turning are wholly unnecessary.

Fig. 21 shows the general arrangement of the connexions for double-current working; the galvanometer G is used for the purpose of indicating whether a station is calling, in case the relay sticks or is out of adjustment. The key K (shown in general plan), when worked, sends reversed currents from the battery B. In cases where "universal battery" working, *i.e.* the working of several instruments from one set of batteries or accumulators, is adopted, the positive and negative currents have to be sent from independent batteries, as shown by fig. 22. The stop *a* of the key K is connected through a switch S with one pole of the battery B, and the stop *b* in the usual way with the other pole. Suppose the arm *c* of the switch S to be in contact with 2; then when the key is manipulated it sends alternately positive and negative currents into the line. If the positive is called the signalling current, the line will be charged positively each time a signal is sent; but as soon as the signal is completed a negative charge is communicated

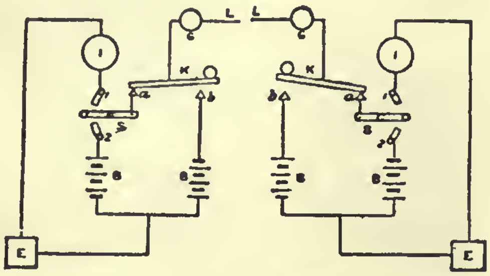

FIG. 22.—Universal Battery Working.

to the line, thus hastening the discharge and the return of the relay tongue to its insulated stop.

Spark coils.

When a local instrument such as a sounder (fig. 15) is worked from a relay, the dying away of the magnetism in the iron cores of the electromagnet, when the relay tongue moves from the marking to the spacing side, *i.e.* when the local battery is cut off, sets up an induced current of high tension, which causes a spark to jump across the contact points of the relay, and by oxidizing them makes it necessary for them to be frequently cleaned. In order to avoid this sparking, every local instrument in the British Postal Telegraph Department has a "spark" coil connected across the terminals of the electromagnet. The spark coil has a resistance about ten times as great as that of the electromagnet it shunts, and the wire of which it is composed is double wound so as to have no retarding effect on the induced current, which circulates through the spark coil instead of jumping in the form of a spark across the contact points. The device is a most effectual one.

Repeaters.

On long circuits worked by the Wheatstone fast-speed apparatus, and especially on those in which a submarine cable is included, it is found necessary to introduce "repeaters" half-way, in order to enable a high speed to be maintained. The speed at which a circuit can be worked depends upon what is known as the "KR" of the line, *i.e.* the product of the total capacity and the total resistance, both the capacity and the resistance having a retarding effect on the signals. By dividing a line into two halves the working speed will be dependent upon the KR of the longest half, and as *both* K and R are directly proportional to the length of the line, the KR product for the half of a circuit is but one quarter that of the whole length of the circuit, and the retardation is correspondingly small. Thus the speed on a line at which the repeater is situated exactly midway will be four times that of the line worked direct. Repeaters (or translators, as they are sometimes termed) are in Great Britain only used on fast-speed circuits; they are in no case found necessary on circuits worked by hand, or at "key speed" as it is called.

Duplex telegraphy.

Duplex telegraphy consists in the simultaneous transmission of two messages, one in each direction, over the same wire. The solution of this problem was attempted by J. W. Gintl of Vienna in 1853 and in the following year by Frischen and by Siemens and Halske. Within a few years several methods had been proposed by different inventors, but none was at first very successful, not from any fault in the principle, but because the effect of electrostatic capacity of the line was left out of account in the early arrangements. The first to introduce a really good practical system of duplex telegraphy, in which this difficulty was sufficiently overcome for land line purposes, was J. B. Stearns of Boston (Mass.). In order that the line between two stations may be worked on the duplex system it is essential that the receiving instrument shall not be acted on by the outgoing currents, but shall respond to incoming currents. The two methods most commonly employed are the differential and bridge methods.

Differential method.

In fig. 23, representing the "differential" method, B is the sending battery, B_1 a resistance equal to that of the battery, R a rheostat and C an adjustable condenser. Suppose the key to be depressed, then a current flows through one winding of the differential relay to line and through the other winding and rheostat to earth. Now if the values of the rheostat and condenser are adjusted so as to make the rise and fall of the outgoing current through both windings of the relay exactly equal, then no effect is produced on the armature of the relay, as the two currents neutralize each other's magnetizing effect.

Incoming currents pass from line through one coil of the relay, the key, and either the battery or battery resistance, according as whether the key is raised or depressed. The result is that the armature of the relay is attracted, and currents are sent through the sounder from the local battery, producing the signals from the distant station. When the key is in the middle position, that is, not making connexion with either the front or back contacts, the received currents pass through both coils of the relay and the rheostat; no interference is, however, felt from this extra resistance because, although the current is halved, it has double the effect on the relay, because it passes through two coils instead of one.

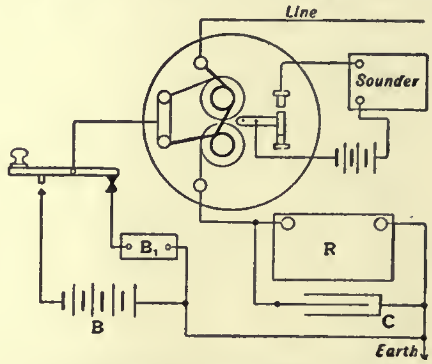

FIG. 23.—Duplex Working: differential method.

Bridge method.

In the "bridge" method (fig. 24), instead of sending the currents through the two coils of a differentially wound relay or receiving instrument as in Frischen's method, two resistances *a* and *b* are inserted, and the receiving instrument is joined between P and Q. The currents thus divide at the point D, and it is clear that if the difference of potential between P and Q is unaffected by closing the sending key, then no change of current will take place in the instrument circuit. The

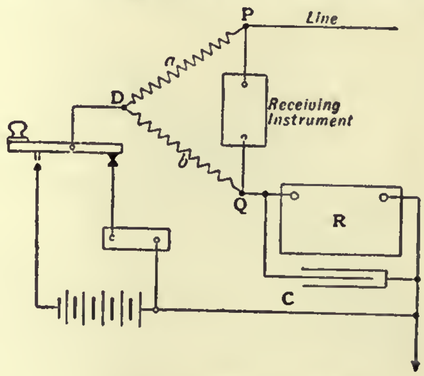

FIG. 24.—Duplex Working: bridge method.

relative potential of P and Q is not affected by the manipulation of the sending key if the resistance of *a* bears the same proportion to that of *b* as the resistance of the line does to that of the resistance R; hence that is the arrangement used. One very great advantage in this method is that the instrument used between P and Q may be of any ordinary form, *i.e.* relay, Hughes, siphon recorder, &c.

Duplex working on cables.

Most important cables, such as those of the Eastern Telegraph Company and the various Atlantic cables, are worked duplex on Muirhead's plan. What may be called a mechanical method of duplexing a cable was described by Lord Kelvin in a patent taken out by him in 1858. In this, as in the ordinary methods, a differentially wound receiving instrument was used, one coil being connected with the cable and the other with the earth; but it differed from other methods in requiring no "artificial" or balancing cable. The compensation was to be obtained by working a slide resistance included in the circuit of the compensating coil, either by the sending key or by clockwork released by the key, so as to vary the resistance in that circuit according to any law which might be required to prevent the receiving instrument being affected by the outgoing current. Four years later Varley patented his artificial cable, which was the first near approach to a successful solution of the duplex problem on the principle now adopted. It was not, however, a sufficiently perfect representation of a laid cable to serve for duplexing cables of more than a few hundred miles in length. By a modification of the bridge method, applied with excellent results by Dr Muirhead to submarine work, condensers are substituted for *a* and *b*, one being also placed in the circuit between P and Q. In this case no current flows from the battery through the line or instruments, the whole action being inductive. As we have already stated, the distribution of the capacity along the resistance R must in submarine cable work be made to correspond very accurately with the distribution of the capacity along the resistance of the cable. This is accomplished by Dr Muirhead in the following manner. One side of a sheet of paraffined paper is covered with a sheet of conducting substance, say tinfoil, and over the other side narrow strips of the same substance are arranged gridironwise to form a continuous circuit along the strip. The breadth and thickness of the strip and the thickness of the paraffined paper are adjusted so that the relative resistance and capacity of this arrangement are the same as those of the cable with which it is intended to be used. A large number of such sheets are prepared and placed together, one over the other, the end of the strip of the first sheet being connected with the beginning of the strip of the second, and so on to the last sheet, the whole representing the conductor of the cable. In the same way all the conducting sheets on the other side of the paper are connected together and form the earth-plate of this artificial cable, thus representing the sea. The leakage through the insulator of the cable is compensated for by connecting high resistances between different points of the strip conductor and the earth coating. Faults or any other irregularity in the cable may be represented by putting resistances of the proper kind into the artificial line. This system of duplexing cables has proved remarkably successful.

Quadruplex telegraphy.

Quadruplex telegraphy consists in the simultaneous transmission of two messages from each end of the line. The only new problem introduced is the simultaneous transmission of two messages in the same direction; this is sometimes called "diplex transmission." The solution of this problem was attempted by Dr J. B. Stark of Vienna in 1855, and during the next ten years it was worked at by Bosscha, Kramer, Maron, Schaak, Schreder, Wartmann and others. The first to attain practical success was Edison, and his method with some modifications is still the one in most general use.

The arrangement is shown in fig. 25, and indicates the general principle involved. K_1 and K_2 are two transmitting keys; the former reverses the direction of the line current, the latter increases the strength irrespective of direction, by joining on another battery when the key is depressed. R_1 and R_2 are relays for receiving the

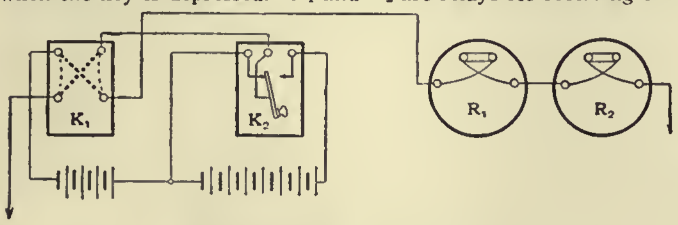

FIG. 25.—Quadruplex Working.

currents; the former is polarized and responds to reversals of current, while the latter is non-polarized and responds only to the increased current from K_2 irrespective of the direction of that current. This arrangement can be duplexed in the way already explained, by providing differential relays and arranging for the outgoing currents to divide differentially through the two relays at each end.

Multiplex telegraphy.

The "multiplex" system devised by Patrick B. Delany (which was adopted to a limited extent in Great Britain, but has now been entirely discarded) had for its object the working of a number of instruments simultaneously on one wire. The general principle of the arrangement of the apparatus is shown by fig. 26. Arms *a* and *b*, one at each station A and B, are connected to the line wire, and are made to rotate simultaneously over metallic segments, 1, 2, 3, 4, and 1′, 2′, 3′, 4′, at the two stations, so that when the arm *a* is on segment 1 at A, then *b* is on segment 1′ at B, and so on. At each station sets of telegraph apparatus are connected to the segments, so that when the arms are kept rotating the set connected to 1 becomes periodically connected to the set connected to 1′, the set connected to 2 to the set connected to 2′, and so on. In practice the number of segments actually employed is much greater than that indicated on the figure, and the segments are arranged in a number of groups, as shown by fig. 27, all the segments 1 being connected together, all the segments 2, all the segments 3, and all the segments 4. To each group is connected a set of apparatus; hence during a complete revolution of the arms a pair of instruments (at station A and station B) will be in communication four times, and the intervals during which any particular set of instruments at the two stations are not in connexion with each other become much smaller than in the case of fig. 26. In practice this subdivision of the segments is so far extended that the intervals of disconnexion become extremely

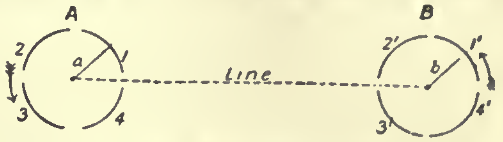

FIG. 26.—Multiplex Working.

small, and each set of apparatus works as if it were alone connected to the line. As many as 162 segments in eight groups are practically used. The arm which moves round over the segments rotates at the rate of three revolutions per second, and is kept in motion by means of an iron toothed wheel, the rim of which is set in close proximity to the poles of an electromagnet. Through this electromagnet pass impulses of current regulated in frequency by a tuning-fork contact breaker; these impulses, acting on the teeth of the iron wheel, by a series of pulls keep it in uniform rotation. If the rates of vibration of the two tuning-forks at the two stations could be maintained precisely the same, the two arms would rotate in synchronism, but as this uniform vibration cannot be exactly

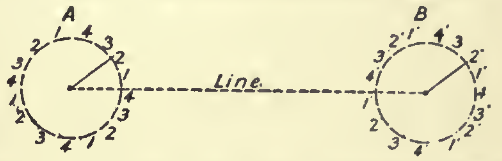

FIG. 27.—Grouping of Segments in Multiplex System.

preserved for any length of time, a means is provided whereby the rate of vibration of either of the forks can be slowed down, so as to retard the rate of rotation of one or other of the arms. This is effected by means of "correcting" segments, of which there are six sets containing three each. Should the rotating arms fail to pass over these correcting segments at their synchronous positions, correcting currents pass to a relay which cuts off momentarily the current actuating the tuning-fork, thereby altering the rate of vibration of the latter until the arms once more run together uniformly. The actual number of sets of apparatus it was possible to work multiplex depended upon the length of the line, for if the latter were long, retardation effects modified the working conditions. Thus between London and Manchester only four sets of apparatus could be worked, but between London and Birmingham, a shorter distance, six sets (the maximum for which the system is adapted) were used.

Chemical Telegraphs.—A method of recording signals in the Morse code, formerly used to a considerable extent, was to use a chemically prepared ribbon of paper. Suppose, for instance, the paper ribbon to be soaked in a solution of iodide of potassium and a light contact spring made to press continuously on its surface as it is pulled forward by the mechanism. Then, if a current is sent from the spring to the roller through the paper, a brown mark will be made by the spring due to the liberation of iodine. This was the principle of the chemical telegraph proposed by Edward Davy in 1838 and of that proposed by Bain in 1846. Several ingenious applications of his method were proposed and practically worked, as, for example, the copying telegraph of Bakewell and of Cros, by means of which a telegram may be transmitted in the sender's own handwriting; the pantelegraph of Caselli; the autographic telegraphs of Meyer, Lenoir, Sawyer and others; and the autographic typo-telegraph of Bonelli; all forms of the apparatus have, however, fallen into disuse.

Automatic Telegraphs.—It was found impossible to make the Morse ink writer so sensitive that it could record signals sent over land lines of several hundred miles in length, if the speed of transmission was very much faster than that which could be effected by hand, and this led to the adoption of automatic methods of transmission. One was proposed by Bain as early as 1846, but it did not come into use. That now employed is, however, practically a development of his idea. It consists in punching, by means of "a puncher," a series of holes in a strip of paper in such a way that, when the strip is sent through another instrument, called the "transmitter," the holes cause the circuit to be closed at the proper times and for the proper proportionate intervals for the message to be correctly printed by the receiving instrument or recorder. The most successful apparatus of this kind is that devised by Wheatstone; others were devised by Siemens and Halske, Garnier, Humaston, Siemens, and Little.

Wheatstone system.

In the Wheatstone automatic apparatus three levers are placed side by side, each acting on a set of small punches and on mechanism for feeding the paper forward a step after each operation of the levers. The punches are arranged as shown in fig. 28, and the levers are adjusted so that the left-hand one moves *a*, *b*, *c* and punches a row of holes across the paper (group 1 in the figure), the middle one moves *b* only and punches a centre hole (2 in the figure), while the right-hand one moves *a*, *b*, *d*, *e* and punches

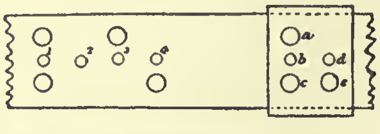

Fig. 28.—Wheatstone Punching Apparatus.

four holes (3 and 4 in the figure). The whole of this operation represents a dot and a dash or the letter "a." The side rows of holes only are used for transmitting the message, the centre row being required for feeding forward the paper in the transmitter. The perforation of the paper when done by hand is usually performed by means of small mallets, but at the central telegraph office in London, and at other large offices, the keys are only used for opening air-valves, the actual punching being done by pneumatic pressure. In this way several thicknesses of paper can be perforated at the same time, which is a great convenience for press work, since copies of the same message have often to be transmitted to several newspapers at the same time.

The mode of using the paper ribbon for the transmission of the message is illustrated in fig. 29. An ebonite beam B is rocked up and down rapidly by a train of mechanism, and moves the cranks

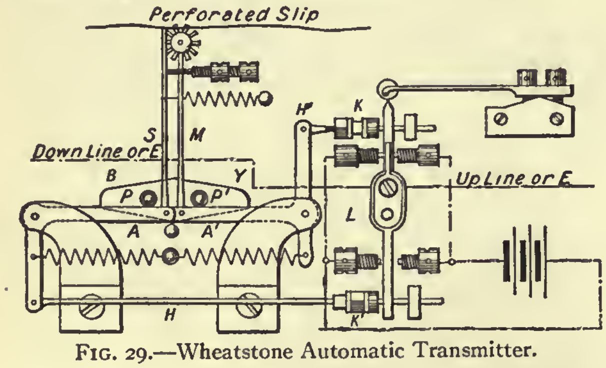

Fig. 29.—Wheatstone Automatic Transmitter.

A and A′ by means of two metal pins P, P′. A and A′ carry two light vertical rods S, M, the one as much in front of the other as there is space between two successive holes in the perforated ribbon. To the other ends of A, A′, rods H, H′ are loosely hinged, their ends passing loosely through holes in the end of the bar L. By means of two collars K, K′, the lever L is made to oscillate in unison with the beam B. The operation is as follows: the paper ribbon or perforated slip is moved forward by its centre row of holes at the proper speed above the upper ends of the rods S, M; should there be no holes in the ribbon then the cranks A, A′ will remain stationary, although the beam B continues to rock, since the rods S, M are pressing against the ribbon and cannot rise. Should, however, a row of holes, like group 1, fig. 28, be in the ribbon, the rod M will first be allowed to pass through the paper, and the corresponding movement of crank A′ will, through the agency of collet K, throw over lever L, and the battery zinc will be put to the line; at the next half stroke of the beam, S will pass through, and crank A by its movement will, through the agency of collet K′, throw over lever L in the reverse direction, so that the battery copper will be put to the line. Thus for a dot, first a negative and then a positive current is sent to the line, the effect of the current continuing during the time required for the paper to travel the space between two holes. Again, suppose groups 3 and 4 to be punched. The first part will be, as before, zinc to the line; at the next half stroke of the beam M will not pass through, as there is no hole in the paper; but at the third half stroke it passes through and copper is put to the line. Thus for a dash the interval between the positive and the negative current is equal to the time the paper takes to travel over twice the space between two successive holes. Hence for sending both a dot and a dash, reverse currents of short duration are sent through the line, but the interval between the reversal is three times as great for the dash as for the dot.

In the receiving instrument the electromagnet is constructed in precisely a similar way to the relay (fig. 20), so that the armature, if pulled into any position by either current, remains in that position, whether the current continues to flow or not, until a reverse current is made to act on the magnet. For the dot the armature is deflected by the first current, the ink-wheel being brought into contact with the paper and after a short interval pulled back by the reverse current. In the case of the dash the ink-wheel is brought into contact with the paper by the first current as before and is pulled back by the reverse current after three times the interval. The armature acts on an inking disk on the principle described above, save only that the disk is supplied with ink from a groove in a second wheel, on which it rolls: the grooved wheel is kept turning with one edge in contact with ink in an ink-well. By this method of transmission the battery is always to the line for the same interval of time, and alternately with opposite poles, so that the effect of electrostatic induction is reduced to a minimum.

Although it is quite possible to obtain good signals at a rate corresponding to 600 letters per minute, in practice it is found that such a high speed is not advisable, as it is difficult or impossible for even the most skilled operators properly to handle and transcribe from the "slip" on which the signals are recorded.

Squier and Crehore system.

In Squier and Crehore's "Synchronograph" system "sine waves" of current, instead of sharp "makes and breaks," or sharp reversals, are employed for transmitting signals, the waves being produced by an alternating-current dynamo, and regulated by means of a perforated paper ribbon, as in the Wheatstone automatic system. The arrangement has been found under certain conditions to give better results than those obtained with sharp reversals.

The undulator.

In the undulator apparatus, which is similar in general principle to the "siphon recorder" used in submarine telegraphy, a spring or falling weight moves a paper strip beneath one end of a fine silver tube, the other end of which dips into a vessel containing ink. The siphon is supported on a vertical axle carrying two armatures which are acted upon by two electromagnets. It is in fact the electromagnet and spindle of a telegraph relay with a siphon in place of the tongue. Screw adjustments are provided for closing or opening the air gap between the electromagnets and armatures, for raising or lowering the siphon, and for adjusting the point of the siphon to the centre or side of the paper strip. The received signals are recorded on the paper strip in an undulating continuous line of ink, and are distinguished by the length of deviation from zero. The amplitude of the signals can be varied in several ways, either by a shunt across the electromagnet, or by altering the tension of the controlling springs or by altering the air gap between electromagnets and armatures. Up to 100 words per minute the signals are easily readable, but beyond that speed they are more difficult to translate, although experts can read them when received at 200 words per minute.

Pollak-Virag System.—In the improved Pollak-Virag system the received signals are recorded in characters similar to ordinary handwriting. The operator actuates a typewriter form of perforator which punches varying groups of holes, representing the different characters, in a paper strip about one inch wide. This slip is then passed through a transmitter fitted with brush contacts and connected to the two line wires of a metallic loop. One circuit is formed by the loop itself, and a second, quite independent, by the two wires in parallel, earthed at each end. At the receiving end there are two telephone receivers, one joined in the loop circuit, the other in the earth return circuit. The diaphragms of these are mechanically connected to a small mirror and control its movement in accordance with the strength and direction of the received currents. One diaphragm gives the mirror a movement in a vertical direction while the other gives it a horizontal motion. The two acting together can thus give the mirror any desired movement within limits. A ray of light is directed upon the mirror, and the motion of the latter, due to the varying strengths and direction of the received currents, is made to write the transmitted signals upon a strip of bromide photographic paper about three inches wide.

The line of writing is of course continuous, there being no break, although there is a space between words. The writing, although not well formed, is sufficiently distinct for ordinary messages; the figures 3, 5, and 8 are, however, liable to be mistaken for each other, being very similar in appearance. The bromide paper is automatically passed through a developing bath, a fixing bath, and drying rollers. This operation occupies about twelve seconds, giving a message written in column form ready for delivery. It is not a system likely to have general application.

Type Printing Telegraphs.—The first considerable improvement in type printing telegraphs was made by D. E. Hughes in 1855.

Hughes instrument. In the Hughes instrument two trains of clockwork mechanism, one at each end of the line, are kept moving at the same speed. Each instrument is provided with a keyboard, resembling that of a small piano, the key levers of which communicate with a circular row of vertical pins. A horizontal arm fixed to a vertical shaft in gear with the mechanism sweeps over these pins at the rate of about two revolutions per second. When a key is depressed, slightly raising one of the pins, the horizontal arm will pass over it and in doing so will momentarily join the battery to the line. The current thus sent to the line may be made either to act directly on the printing instrument or to close a local circuit by means of a relay. For simplicity we will suppose direct action. The current then passes through the coils of an electromagnet, which releases the printing mechanism. The electromagnet consists of two coils, each wound on a soft iron core fixed to the poles of a strong permanent horse-shoe magnet. The armature of the electromagnet is normally attracted by the effect of the permanent magnet, but it is furnished with two antagonistic springs tending to throw it upwards. These springs are so adjusted that they are not quite able to release the armature. When a current comes in from line it passes through the electromagnet in such a direction as to weaken the effect of the permanent magnet; hence the springs are able to release the armature, which rises smartly and in its turn releases the printing mechanism. Either a weight or a motor is used for making the movements of the mechanism required to effect the printing of the signals. The type-wheel is carried round continuously by the mechanism to which it is attached by a friction disk and ratchet drive. An axle carrying four cams is normally at rest, but it is thrown into gear with the mechanism when the armature rises, makes one complete revolution, and comes to rest ready for the next signal. In its revolution one of its cams engages with the correcting wheel attached to the type-wheel in order to ensure that the latter is in the correct position for printing a complete letter; the second cam lifts the paper against the type-wheel and prints the letter; the third moves forward the paper tape one space to be ready for the printing of the next letter; and the last cam replaces the armature on the cores of the electromagnet. This complete operation occupies about one-twelfth of a second. It is of course necessary that two instruments working together should have the same speed. This is obtained by causing one of them to send a series of signals from one particular key, while the operator at the other station adjusts his speed until he receives the same signal after short-circuiting his electromagnet for ten revolutions. Both type-wheels are then set to zero by the lever provided for that purpose, and released by the current from the letter-blank key; then all subsequent signals will be recorded similarly at the sending and receiving ends. If by any chance wrong signals are printed or the instruments get out of phase, the sender is stopped by the receiver sending a few signals, after which both type-wheels are again set to zero and correspondence continued. This system of telegraphic printing has a great advantage over the step-by-step system in avoiding the necessity for the rapidly acting electric escapement, which, however skilfully planned and executed, is always liable to failure when worked too rapidly. In Hughes's instrument almost perfect accuracy and certainty have been attained; and in actual practice it has proved to be decidedly superior to all previous type-printing telegraphs, not only in speed and accuracy, but in less liability to mechanical derangement from wear and tear and from accident. It involves many novel features: the receiving electromagnet is of peculiar construction and remarkable efficiency and the transmitting apparatus has a contrivance to prevent unintentional repetitions of a letter through the operator holding his finger too long on a key. This instrument was for some years extensively used in the United States, until superseded by G. M. Phelps's modification of it, known as the "American combination printing telegraph," because it embodied part of Hughes's and part of House's instruments. With this modified form somewhat greater speed was obtained, but it was found difficult to drive, requiring the use of steam or some such motive-power. In a subsequent modification introduced in 1875 an electromotor was applied to drive the printing mechanism. This allowed a shorter train and stronger wheelwork to be used, securing more certain action, and involving less risk of derangement. Hughes's form was taken up by the French government in 1860, and is very largely in use not only in France but in all European countries, including Great Britain.

Baudot system. The system brought out in 1874 by Émile Baudot and since considerably developed is a multiplex system giving from two to six channels on one wire, each channel giving a working speed of thirty words per minute. The channels can be worked in either direction according to the traffic requirements. The line is joined at each end to distributors which are arranged to maintain uniform speed and to control their respective receivers. Each channel consists of a keyboard and receiver both electrically connected to certain parts of the distributor. The keyboard has five keys similar to those of a piano, and the letters and figures are obtained by the different combinations which can be formed by the raised and depressed keys. In the raised position a negative battery is connected to the distributor and in the depressed position a positive battery. At regular intervals a rotating arm on the distributor connects the five keys of each keyboard to line, thus passing the signals to the distant station, where they pass through the distributor and certain relays which repeat the currents corresponding to the depressed keys and actuate electromagnets in the receivers. Each receiver is provided with five electromagnets corresponding to the five keys of the keyboard, and the armatures of the electromagnets can thus repeat the various combinations for all the signals allocated to the different combinations of the keys. When a combination of signals has been received and the armatures have taken up their respective positions corresponding to the transmitting keyboard, certain mechanism in the receiver translates the position of the five armatures into a mechanical movement which lifts the paper tape against a type-wheel and prints the corresponding letter. The movement for any particular combination of armatures can only take place once per revolution of the type-wheel and at one particular place. The signals must therefore be sent at regular intervals, and to ensure this being done correctly a telephone or time-tapper is provided at each keyboard to warn the operator of the correct moment to depress his keys. The Baudot apparatus can have certain channels extended so as to form a means of continuous communication between one station and two or three others by means of one line. It can also be duplexed or repeated similar to any other telegraph system.

Murray system. In the Murray system the messages are first prepared in the form of a strip of perforated paper about half an inch wide. Perforating machines equipped with typewriter keyboards are used for the preparation of the messages, two or three keyboard perforators being employed at each end of the telegraph lines on which the Murray system is used. The messages in the form of perforated tape are then passed through an automatic transmitter, something like a Wheatstone transmitter, at a speed of about 100 words a minute. At the receiving station electrical mechanisms record the signals once more as perforations in a paper strip forming an exact replica of the transmitting tape. This received perforated tape is then used to control what is known as the printer or automatic typewriter, a machine that translates the tape perforations into letters and prints the messages in Roman type in page form. This printer is purely mechanical, and its speed is very high. An experimental printer constructed about the middle of 1908 by the British Post Office, operated successfully at the rate of 210 words (1260 letters) per minute. The usual working speed is from 100 to 120 words per minute. The Murray automatic system was designed specially for dealing with heavy traffic on long lines. As it uses the Baudot telegraph alphabet it has an advantage in theory over the Wheatstone using the Morse alphabet in regard to the speed that can be obtained on a long telegraph line in the ratio of eight to five, and this theoretical advantage is more or less realized in practice. The Murray automatic system is not regarded as suitable for short telegraph lines or moderate traffic, printing telegraphs on the multiplex principle being considered preferable in such circumstances. One of the longest circuits upon which it has been successfully worked is that between St Petersburg and Omsk, a distance of approximately 2400 miles of iron wire, with three repeating stations. As in some other systems retransmission is effected from the received perforated tape.

Creed system. The Creed system is a development of the Morse-Wheatstone system, and provides a keyboard perforator which punches Morse letters or figures on a paper strip by depressing typewriter keys. The slips are passed through an ordinary Wheatstone transmitter and actuate Wheatstone receiving apparatus which in turn controls a "Creed receiving perforator." This machine reproduces a copy of the original transmitting slip, which can be passed on to any other Wheatstone circuit or can be run through a "Creed printer," which is a pneumatic machine actuating a typewriter by means of valves. Messages are thus typed upon a slip which is gummed to the telegraph form. The speed of the receiving perforator ranges from 20 to 150 words per minute.

Rowland system. In the Rowland multiple method of telegraphic working, the transmitter consists of a mechanical keyboard provided with a series of levers, which effect certain combinations of positive and negative currents for each letter. These currents are furnished by an alternator which transmits sine currents over the line and operates a motor at the distant end of the line, both machines running in synchronism. At the receiving end of the circuit a shaft is coupled to the motor; this is provided with gearing which rotates four combining commutators and four type-wheels, which print the letters on the band of paper. There are four transmitters and four receivers, which are operated independently by means of an adaptation of the multiplex system of working, and each circuit is provided with a number of segments set apart for its own use. Each transmitter is therefore able to transmit a separate series of positive and negative currents in different combinations; these are distributed, by suitably arranged distributors and relays at the receiving end of the line, into their respective receivers. The function of the "combiner" in each receiving instrument is so to group the received combination of positive and negative currents that they operate polarized relays in such a manner that the position of the tongues corresponds with the operation of the levers on the transmitter. Since each letter is represented by a specific combination of positive and negative currents, it is possible, by means of the combinations, to close a local circuit at any given interval, and so cause the paper to be pressed against the periphery of the type-wheel at the time when the letter required is opposite. The paper is also caused to advance automatically for each letter, start a fresh line, and also to commence a fresh form at the completion of each message.

Telautograph.—Instruments such as the telautograph and telewriter are apparatus for transmitting a facsimile of handwriting inscribed on a paper at one end of a line, the reproduction being made automatically at the other end of the line at the same time that the message is being written.

A successful apparatus for effecting this was devised by Cowper and was known as the writing telegraph. The telautograph is on a similar principle to the Cowper apparatus, the motion of the transmitting pencil or stylus used in writing being resolved by a system of levers into two component rectilinear motions, which are used to control and vary the currents in two distinct electrical circuits. By the action of the two variable currents on the electromagnetic mechanism in the receiver, the two component motions are reproduced and by their combined action on a second system of levers the receiving pen is caused to duplicate the motions of the transmitting pencil. The motion communicated to rollers by the pencil serves to cut resistance in or out of the two line circuits which are connected to the rollers, and thus two independent variable line currents are obtained. In the receiver there is a strong electromagnet, excited by a local current, which has in its circuit two annular air gaps, across which the magnetic field is practically uniform and constant. In these annular spaces there are suspended by springs two light coils of fine copper wire, capable of being moved vertically, and connected in such a manner as to be traversed by the two variable line currents from the transmitter. These coils are drawn down, by the magnetic action of the field on the currents in the coils, into the annular spaces, against the pull of the springs, more or less strongly, according to the strengths of the two line currents. Each coil is attached to a shaft by a bell crank arrangement, and to these shafts there is secured a system of levers similar to that at the transmitter carrying the receiving pencil at the junction. The shafts are turned by the pull of the magnet upon the coils, and the motions of the transmitting pencil are thus reproduced.

Korn telephotograph system.

The Korn telephotographic apparatus is based on the principle of an apparatus devised by Shelford Bidwell in 1881 for the electrical transmission of pictures to a distance, in which use was made of the change in electrical resistance which selenium undergoes when acted upon by light. In the Korn apparatus the light from a Nernst electric lamp is concentrated to a point by means of a lens on the original picture, which is wound on a glass cylinder in the shape of a transparent photographic film. A totally reflecting prism placed inside the glass cylinder projects the light which penetrates the film upon a selenium cell situated at the end of the cylinder. An illumination of variable intensity (according to the deeper or lighter shades of the portion of the picture on which the light falls) thus takes place on the selenium cell. As the glass cylinder, driven by a motor, revolves upon its axis while also advancing (by means of a screw thread on the axis), all portions of the picture are successively brought under the beam or pencil of light and cause a beam of varying intensity to fall on the selenium cell. Owing to the variable illumination of the selenium thus produced, the resistance of the latter, and therefore the intensity of the current sent through the line to the receiving station by the battery, will be altered accordingly. At the receiving station a cylinder—which revolves synchronously with the transmitting cylinder—is covered with a photographic film or paper, upon a point of which a pencil of light from a Nernst lamp is concentrated. Before reaching the paper the light passes through perforations in two iron plates which are, in fact, the pole pieces of a strong electromagnet; between these is an aluminium shutter which is attached to two parallel wires or thin strips. When there is no current the shutter covers the perforations and no light passes, but when a current traverses the wires they are depressed by electromagnetic action, carrying the shutter with them, and a quantity of light proportional to the current strength is admitted through the perforations. By means of this "light-relay" the intensity of the light acting at any moment upon the sensitized paper is made proportional to the illumination of the selenium in the transmitter. To eliminate the sluggish action of the selenium transmitter a selenium cell similar to that at the transmitting station is arranged at the receiving apparatus, and exposed to precisely similar variations of light, the arrangement being such that the lag of this cell counteracts the lag of the transmitting cell. The synchronous revolutions of the transmitting cylinders are effected by making one cylinder revolve slightly faster than the other; after each revolution the cylinder which is accelerated is arrested for a moment by means of a special relay until the difference of speed is accurately compensated for. This device was originally adopted in the d'Arlincourt copying telegraph.

Submarine Telegraphy.—For working long submarine cables the apparatus ordinarily employed on land lines cannot be used, as the retarding effect of the electrostatic capacity of the cable is so marked that signals fail to be recorded except at a very slow speed of working. The transmitted signals or electric impulses, which on a land line are sharply defined when received, become attenuated and prolonged in the case of a long cable, and are unable to actuate the comparatively heavy moving parts of which the land line instruments are formed. Other patterns of apparatus are therefore necessary.

The arrangement of the apparatus for working some of the most recent cables is shown in Fig. 30. The cable is supposed to be worked duplex; but, if S, C_1, C_2, and AC are removed and the key connected directly with C_3, the arrangement for simplex working is obtained. The apparatus consists of a sending battery B, a reversing transmitting key K, a slide of small resistance S, three condensers C_1, C_2, C_3, an artificial cable AC, the receiving instruments I and G, and one or more resistances R for adjusting the leakage current. The peculiar construction of AC has been already referred to. The conductor of the cable is practically insulated, as the condensers in the bridge have a very high resistance; hence no appreciable current ever flows into or out of the line. Two receiving instruments, a siphon recorder and a mirror galvanometer, are shown; one only is absolutely necessary, but it is convenient

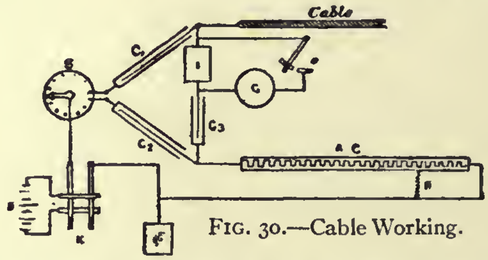

FIG. 30.—Cable Working.

to have the galvanometer ready, so that in case of accident to the recorder it may be at once switched into circuit by the switch *s*. When one of the levers of K is depressed, the condenser C_1 and the cable, and the condenser C_2 and the artificial cable, are simultaneously charged in series; but, if the capacity of C_1 bears the same proportion to the capacity of the cable as the capacity of C_2 bears to the capacity of the artificial cable, and if the other adjustments are properly made, no charge will be communicated to C_3. After a very short interval of time, the length of which depends on the inductive retardation of the cable, the condensers corresponding to C_1 and C_3 at the other end begin to be charged from the cable, and since the charge of C_3 passes through the receiving instrument I or G the signal is recorded. The charging of C_3 at the receiving end will take place, no matter what is the absolute potential of the condensers, consequently the incoming signals are not affected by those which are being transmitted from that end. In actual practice the receiving instrument is so sensitive that the difference of potential between the two coatings of the condenser C_3 produced by the incoming signal is only a very small fraction of the potential of the battery B. When the key is released the condensers and cables at once begin to return to zero potential, and if the key is depressed and released several times in rapid succession the cable is divided into sections of varying potential, which travel rapidly towards the receiving end, and indicate their arrival there by producing corresponding fluctuations in the charge of the condenser C_3. All cables of any great length are worked by reverse currents. A modification (known as the cable code) of the ordinary single needle alphabet is used; that is to say, currents in one direction indicate dots and in the other direction dashes.

The general principle on which the instruments for working long submarine cables are based is that of making the moving parts very light and perfectly free to follow the comparatively slow rise and fall of the electric impulses or waves. The simplest form of receiving instrument (formerly much used) is known as the "mirror."

Mirror Instruments.

In this instrument a small and very light mirror, about $\frac{3}{8}$ in. in diameter, attached to a stretched fibre and having a small magnetic needle fixed to its back, is arranged within a galvanometer coil so that the influence of the latter causes the mirror (through the action of the magnetic needle) to be turned through a small angle in one direction or the other according to the direction of the current through the coil. A ray of light from a lamp is thrown on the mirror, whence it is reflected upon a white surface or scale set at a distance of about 3 ft., forming a bright spot on the surface; the slightest angular deflexion of the mirror, owing to its distance from the scale, moves the spot of light a very appreciable distance to the right or left according to the direction of the angular movement. These indications form the telegraph alphabet and are read in the same manner as in the case of the "single needle" instrument used on land.

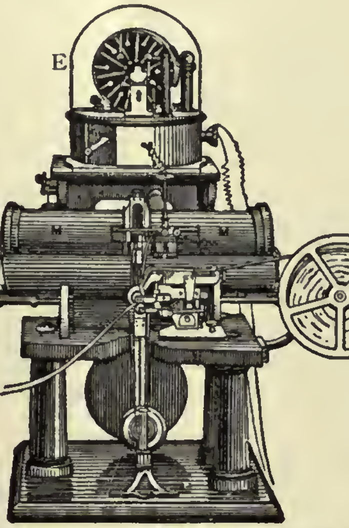

FIG. 31.—Lord Kelvin's early Siphon Recorder.

Spark recorder. The spark recorder in some respects foreshadowed the more perfect instrument—the siphon recorder—which was introduced some years later. Its action was as follows. To an indicator, suitably supported, a to-and-fro motion was given by the electromagnetic actions due to the electric currents constituting the signals. The indicator was connected with a Ruhmkorff coil or other equivalent apparatus, designed to cause a continual succession of sparks to pass between the indicator and a metal plate situated beneath it and having a plane surface parallel to its line of motion. Over the surface of the plate and between it and the indicator there was passed, at a regularly uniform speed, in a direction perpendicular to the line of motion of the indicator, a material capable of being acted on physically by the sparks, through either their chemical action, their heat, or their perforating force. The record of the signals given by this instrument was an undulating line of fine perforations or spots, and the character and succession of the undulations were used to interpret the signals desired to be sent.

Siphon recorder. In the original form of the siphon recorder (fig. 31), for which Lord Kelvin obtained his first patent in 1867, the indicator consisted of a light rectangular signal-coil of fine wire, suspended between the poles of two powerful electromagnets M, M so as to be free to move about its longer axis, which is vertical, and so joined that the electric signal currents through the cable pass through it. A fine glass siphon tube is suspended with freedom to move in only one degree, and is connected with the signal-coil and moves with it. The short leg of the siphon tube dips into an insulated ink-bottle, so that the ink it contains becomes electrified, while the long leg has its open end at a very small distance from a brass table, placed with its surface parallel to the plane in which the mouth of the leg moves, and over which a slip of paper may be passed at a uniform rate, as in the spark recorder. The ink is electrified by a small induction electrical machine E placed on the top of the instrument; this causes it to fall in very minute drops from the open end of the siphon tube upon the brass table or the paper slip passing over it. When therefore the signal-coil moves in obedience to the electric signal-currents passed through it, the motion communicated to the siphon is recorded on the moving slip of paper by a wavy line of ink-marks very close together. The interpretation of the signals is according to the Morse code,—the dot and dash being represented by deflexions of the line of dots to one side or other of the centre line of the paper. A very much simpler form of siphon recorder, constructed by Dr Muirhead, is now in general use. The magnet between the poles of which the rectangular signal coil moves is built up of a number of thin flat horseshoe-shaped permanent magnets of a special quality of steel, and is provided with adjustable pole pieces. The signal coil is suspended by fibres and is mounted together with a fixed soft iron core on a brass plate affixed to a rack, with which a pinion operated by a milled head screw engages. To the brass plate is attached an arm carrying the bridge piece. A wire or fibre carrying the aluminium siphon cradle is stretched across this bridge piece, and on it is also mounted the small electromagnet, forming part of the "vibrator" arrangement with its hinged armature, to which one end of the stretched wire carrying the siphon is fastened. The ink-box is made adjustable, being carried by an arm attached to a pillar provided with a rack with which a pinion operated by a milled head screw engages. The motor is usually supported on a platform at the back of the instrument, its driving-wheel being connected to the shaft of the paper roller by means of a spirally wound steel band. In what is known as the "hybrid" form of recorder the permanent magnets are provided with windings of insulated copper wire; the object of these windings is to provide a means of "refreshing" the magnets by means of a strong current temporarily sent through the coils when required, as it has been found that, owing to magnetic leakage and other causes, the magnets tend to lose their power, especially in hot climates. Instruments of the siphon recorder type have been made to work both with and without electrification of the ink. In the latter case, which is the standard practice, mechanical vibration of the siphon is substituted in the place of electrification of the ink, so as to eliminate the effect of atmospheric conditions which frequently caused discontinuity in the flow of ink.

Fig. 33 shows a facsimile of part of a message received and recorded by a siphon recorder, such as that of fig. 31, from one of the Eastern Telegraph Company's cables about 830 miles long. As the earth is used for completing the electric circuit, the signals received on such sensitive instruments as these are liable to be disturbed by the return currents of other systems in their immediate neighbourhood, which also use the earth as return, when such are of the magnitude generated by the working of electric tramways or similar undertakings, and to obviate this it is necessary to form the "earth" for the cable a few miles out at sea and make connexion thereto by an insulated return wire, which is enclosed in the same sheathing as the core of the main cable.

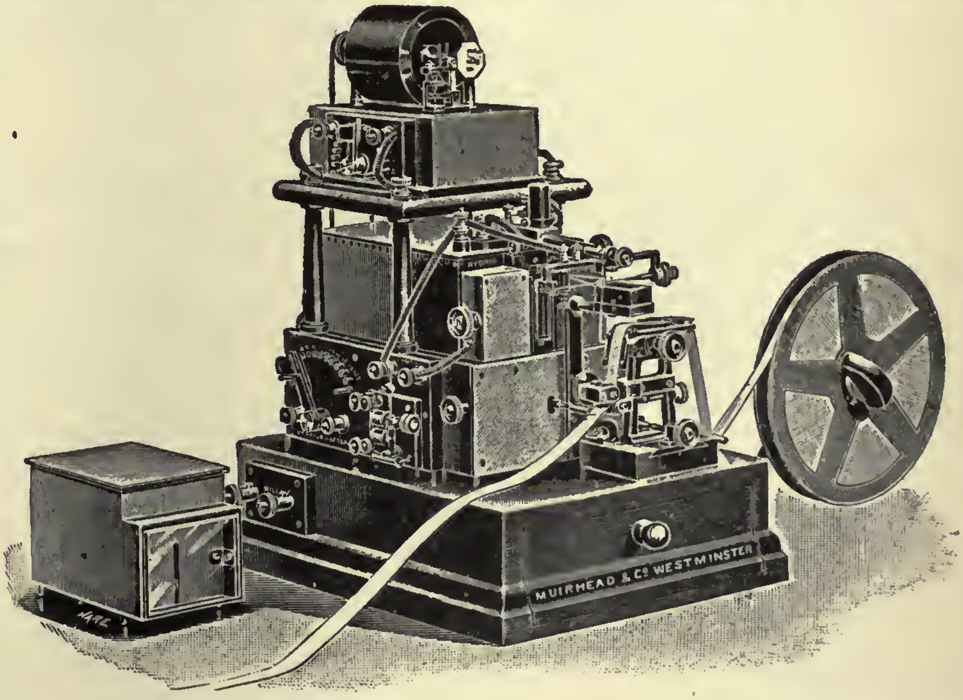

FIG. 32.—Muirhead's Siphon Recorder.

The heavier cores, with the consequent advance in speed of working attainable, have necessitated the introduction of automatic sending, the instruments adopted being in general a modification of the Wheatstone transmitter adapted to the form of cable signals, while the regularity of transmission thus secured has caused its introduction even on circuits where the speed cannot exceed that of the ordinary operator's hand signalling.

Automatic curb sender.

The automatic curb sender was originally designed by Lord Kelvin for the purpose of diminishing the effect of inductive retardation in long cables. In ordinary hand-sending the end of the cable is put to one or the other pole of the battery and to earth alternately, the relative time during which it is to battery and to earth depending to a great extent on the operator. By the automatic curb sender the cable is put to one or the other pole of the battery and then to the reverse pole for definite proportionate times during each signal. The cable is thus charged first positively and then negatively, or *vice versa*, for each signal. Owing to the difficulty of maintaining perfect balance on duplexed cables, curb sending is not now used, but the signals are transmitted by means of an apparatus similar to the Wheatstone automatic transmitter used on land lines and differing from the latter only in regard to the alphabet employed; the signals from the transmitter actuate a relay having heavy armatures which in turn transmit the signals to the cable; this arrangement gives very firm signals, a point of great importance for good working. The actual speed or rate of signalling is given approximately by the formula, $S=120/(KR)$, where S is the number of words per minute, R the total resistance of the conductor in ohms, and K the total capacity in farads. The speed of a cable is given in words per minute, the conventional number of five letters per word being understood, though in actual practice, owing to the extensive use of special codes, the number of letters per word is really between eight and nine; and this forms a considerable factor in lowering the earning capacity of a cable.

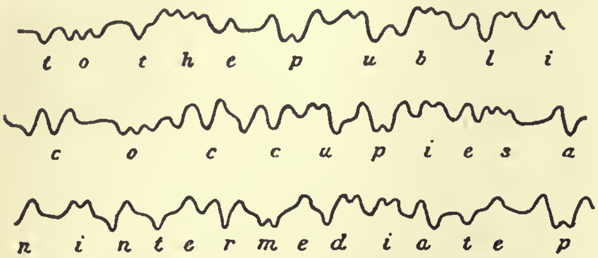

FIG. 33.—Facsimile of Siphon Recorder Message.

Relays.

A relay capable of working at the end of a long cable has long been a desideratum. The difficulty experienced is that of securing a good electrical contact under the very slight pressure obtainable from an instrument excited by attenuated arrival-currents. In an instrument invented by S. G. Brown (Brit. Pat. 1434 of 1899) it is sought to overcome this difficulty by causing the point of a contact-arm, representing the siphon in the ordinary form of recorder, to traverse the cylindrical surface of a rapidly rotating drum. This surface is divided into two parallel halves by a short insulating space on which the arm normally rests, so that two separate conducting surfaces are provided, with either one of which the arm will make contact in its excursions in one direction or the other from the central position, the direction and duration of contact being governed by the motion of the suspended coil. The great reduction in friction and in electrical resistance of the contact thus effected between the recurved end of the arm and the rotating surface secures the transmission of signals at such a high rate of speed that the combination of this relay with a special form of curb sender allows of the re-transmission of signals into a second cable at a speed not less than that of the siphon recorder worked in the usual way. The special form of curb sender mentioned, termed the "Interpolator," has been devised so as to secure the correct re-transmission of any given number of consecutive elements of a letter which are of the same sign, for when signals are received at the end of a long cable the relay arm will not return to its zero position between consecutive elements of the same sign, but will remain on the respective contact surface during the whole time occupied by such consecutive elements. The instrument consists of two cams, the form of which regulates the components of the curbed signal, one cam being for the dot element and the other for the dash element, which by their sequence give the letter signals; these cams, by means of clutches controlled by the relay, are mechanically rotated by clockwork, the speed of rotation being approximately adjusted to the rate of transmission of a single element, so that the requisite number of consecutive elements is transmitted corresponding to the duration of contact of the relay arm with the side controlling that particular element. By a modification of this apparatus the message, instead of being immediately re-transmitted into the second cable, can be punched on a paper slip, which can be inserted in the usual way into an automatic transmitter, so as to send either cable or Morse signals. Fig. 34 shows the effect of the interpolator in dissecting the consecutive elements of any letter combination. Another instrument (see Brit. Pat. No. 18,261 of 1898) is what may be termed a magnifier, since signals so small as to be almost unreadable on direct record are rendered perfectly legible. The recorder coil is connected mechanically to a second similar coil, which is suspended between the poles of a laminated magnet, so that the motions of the two are similar. This magnet is excited by an alternating current, and the current induced in the second coil is after rectification sent through an ordinary siphon recorder. As the direction and intensity of this induced current are a function of the position of the second coil in its field, and as this position is determined by its mechanical connexion with the recorder coil, it is evident that, by a suitable choice of the electrical elements of the second coil and its alternating field, the indications on the siphon recorder can be magnified to any reasonable extent.

Magnetic shunt.

By means of a "magnetic shunt" Brown succeeded in increasing the working speed of long submarine cables to the extent of 10 to 15 per cent. The magnetic shunt (which is connected across the receiving instrument) consists of a low resistance coil of some 2000 turns of insulated copper wire, enclosed in a laminated iron circuit, and connected at intervals to a number of terminals so that equal increments of inductance may be obtained. The use of the iron core renders it possible to produce a high inductive effect with a low resistance coil, and thus obtain the necessary slow time constant to which is due the success of this type of magnetic shunt on cable signals. The shunts usually employed with the drum relay (referred to above) have each a resistance of about 30 ohms and an inductance of 20, 30 and 40 henrys respectively. The explanation of the action of the shunt is that all slowly varying currents affect the coil of the receiving instrument and its shunt in inverse proportion to their respective resistances; whereas with the comparatively rapid variations of current used in signalling the coil is forced at the beginning of each element of a signal to take *more*, and at the end of the element *less* of the total arrival current from the cable than would traverse it if the shunt were non-inductive.

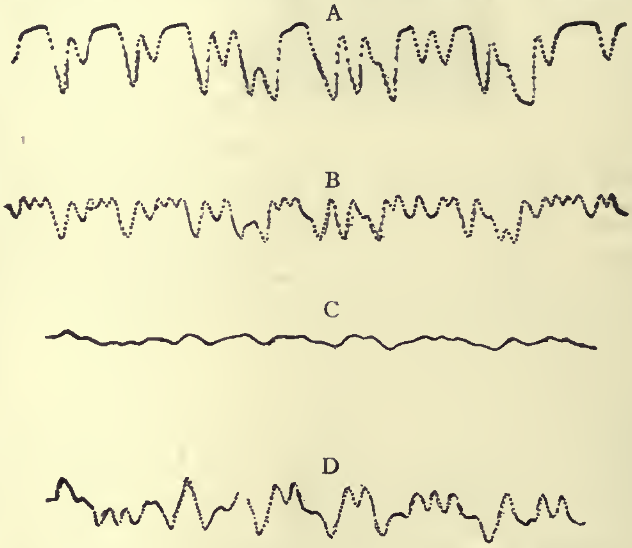

FIG. 34.—Taylor and Dearlove's Interpolator with Brown's Improvements.

A, slip as received on recorder, using ordinary relays for translating on to second cable; B, slip as received on recorder, when interpolator is used at intermediate station, for sending on to second cable; C (four cells through a line, $KR=3\cdot6$), signals with recorder under ordinary conditions; D, all conditions the same as in C, but magnifying relay inserted between the end of the line and the recorder.

Magnetic bridge.

For duplex working a "magnetic bridge" is used. This consists of a low resistance coil of copper wire enclosed in a laminated iron circuit similar to the magnetic shunt already described. The coil, however, is arranged so that the sending current enters an adjustable mid-point in the coil and passes through the two halves of the winding to the ends connected to the cable and artificial line respectively. The receiving instrument is joined up across these ends in the usual manner. The action of this bridge resembles the magnetic shunt in its effect on the received signals, as the direction of the winding is the same throughout its length, and thus the full inductive action is produced for curbing purposes. To the sending currents, however, the bridge offers only apparent ohmic resistance due to the fact that the current entering the mid-point of the winding flows through the two halves or arms in opposite direction, and, owing to the winding being on the same iron core, the mutual inductive effect of the two arms on one another neutralizes the self-induction to the sending currents. The average total inductive value of these bridges to received signals is about 40 henrys, and the coil is so arranged that the arms contain three sections or blocks of winding each, two of which are joined up to strap connexions, and the third divided into small subdivisions to any terminals of which the cross circuit connexions may be affixed. By this arrangement of the coil winding, similar sections can be thrown in or out of circuit with both arms, and also so combined that any amount of inductance suitable to every class of cable may be obtained. The bridge is provided with two adjustments:—(1) a variable "apex,' having several turns of the winding between each stud to permit of the arms being thrown slightly out of balance as a rough compensation for the differences in the cable and artificial line; and (2) an additional "fine" adjustment in one of the arms by which the small daily balance variations may be corrected. As with other duplex systems it is possible to obtain several approximately correct adjustments with the bridge and its accessories, but only one gives a true balance, and careful experiment is required to make sure that this is obtained. The advantage of using the magnetic bridge duplex method is that the maximum current is sent to line or cable, and the receiving system benefits accordingly. (H. R. K.)

Commercial Aspects.

The earliest practical trial of electrical telegraphy was made in 1837 on the London and North Western Railway, and the first public line under the patent of Wheatstone and Cooke was laid from Paddington to Slough on the Great Western Railway in 1843. At first the use of the telegraph was almost entirely confined to railways. The Electric Telegraph Company, formed to undertake the business of transmitting telegrams, was incorporated in 1846. For some time it restricted its operations to constructing and maintaining railway telegraphs and was not commercially successful. Its tariff was 1s. for 20 words within a radius of 50 miles, 1s. 6d. within 100 miles, 5s. if exceeding 100 miles. After about five years great improvements were made in the working of the telegraphs and the industry began to make progress. Telegraphic money orders were established in 1850; a cable was laid between Dover and Calais, and in November 1851 the stock exchanges of London and Paris were able for the first time to compare prices during business hours of the same day; numerous companies were formed, some of which were independent of the railways, and keen competition led to considerable extensions of wires and reduction of tariffs, with the result that a large increase in the volume of business took place. In the period from 1855 to 1868 the number of messages carried annually by all the telegraph companies of the United Kingdom increased from 1,017,529 to 5,781,989, or an average annual increase of 16·36 per cent. During this period the Electric Telegraph Company's average receipts per message fell from 4s. 1½d. to 2s. 0¾d., or just over half, while the number of messages increased nearly fourfold. The working expenses were reduced in a progressively larger ratio, *e.g.* in 1859 the average working expenses were 2s. 7d. per message or more than 65 per cent. of the receipts, while in 1869 they were 1s. 0¼d. per message or only 51 per cent. of the receipts. Much dissatisfaction was felt because the larger towns where competition had been most keen were unduly benefited to the neglect of smaller towns where the business was comparatively less profitable, but it must be remembered that the telegraph lines followed the railways and that many towns were not served owing to their opposition to the railways.

In 1856 the Edinburgh Chamber of Commerce began an agitation for the purchase by the government of the telegraphs, and other chambers of commerce in Great Britain joined the agitation, which was strongly supported by the Press. In 1865 the Postmaster-General (Lord Stanley) commissioned Mr F. T. Scudamore, second secretary to the Post Office, to inquire and report whether the electric telegraph service could be beneficially worked by the Post Office, and whether it would entail any very large expenditure on the Post Office beyond the purchase of the rights. At that time the total number of places supplied with telegraphic communication by all the companies collectively, including railway stations, was 2500, whereas the number of places having postal communications was over 10,000. Under the then existing telegraphic tariff the charge in Great Britain was a shilling for a twenty-word message over a distance not exceeding 100 miles; 1s. 6d. for a like message over distances from 100 to 200 miles; 2s. when exceeding 500 miles. For a message between Great Britain and Ireland the charge ranged from 3s. to 6s.; to Jersey or Guernsey it was 7s. 8d. There were also extra charges under contingent regulations of great complexity, which commonly added 50 per cent. to the primary charge, and frequently doubled it. Mr Scudamore, who was regarded as the author of the bill for the acquisition of the telegraph systems, reported that the charges made by the telegraph companies were too high and tended to check the growth of telegraphy; that there were frequent delays of messages; that many important districts were unprovided with facilities; that in many places the telegraph office was inconveniently remote from the centre of business and was open for too small a portion of the day; that little or no improvement could be expected so long as the working of the telegraphs was conducted by commercial companies striving chiefly to earn a dividend and engaged in wasteful competition with each other; that the growth of telegraphy had been greatly stimulated in Belgium and Switzerland by the annexation of the telegraphs to the Post Offices of those countries and the consequent adoption of a low scale of charges; that in Great Britain like results would follow the adoption of like means, and that the association of the telegraphs with the Post Office would produce great advantage to the public and ultimately a large revenue to the state.

In support of these views he reported that in Belgium in 1863 a reduction of 33 per cent. in the charge had been followed by an increase of 80 per cent. in the number of telegrams, and that in 1886 a reduction of 50 per cent. in the charge had been followed by an increase of 85 per cent. in the traffic; and similar statistics pointing to increase of business consequent on reduction of rates were produced in regard to France, Switzerland and Prussia. The relative backwardness of telegraphy in Great Britain was attributed to high charges made by the companies and to restricted facilities. Some of the complaints against the companies, however, were exaggerated, and the estimates formed of the possible commercial development of telegraphy were optimistic. The basis for these estimates was the experience of other countries, which, however, did not justify the expectation that a large increase of business consequent on reduction of rates could be obtained without serious diminution of profit. The Belgian state telegraphs were started in 1850 and were at first very profitable, but for the years 1866–9 they yielded an average profit of only 2·8 per cent., and subsequently failed to earn operating expenses, the reasons for the steady decline of the profits being the opening of relatively unprofitable lines and offices, increases in wages, and a diminution in growth of the foreign and transit messages which had constituted the most profitable part of the whole business. The Belgian government endeavoured by reducing rates and increasing facilities to stimulate inland telegraphy in the hope of thereby increasing the profits of the department. But these expectations were not realized. Upwards of 100 telegraph offices in Belgium despatched on the average less than one telegram per day, and some offices despatched less than one a month. Similar experience was adduced by the working of the state telegraphs in Switzerland and in France. The profits when earned were derived mainly from foreign messages and transit messages between foreign countries, while the receipts from inland messages did not always cover expenses. In 1868 there were in France over 300 telegraph offices whose average receipts did not exceed £8 per annum. In that year the Swiss government reduced the rate for inland telegrams by one-half, and the traffic immediately doubled, but the cost of carrying on the service increased in a larger ratio.

The experience of the telegraph companies in the United Kingdom, moreover, showed that a uniform rate, irrespective of distance, of 1s. for 20 words, addressed free, was not remunerative in the then state of telegraphy, which made it necessary for messages to be re-transmitted at intervals of about 300 miles. In 1861 the United Kingdom Telegraph Company began a competition with the other companies on the basis of a 1s. rate, and the old-established companies were forced to adopt this rate between all points served by the United Kingdom

Company; but after a trial of four years it was found that a uniform 1s. rate irrespective of distance had not justified itself, and that for any but very short distances the tariff was "utterly unremunerative" notwithstanding a very large increase in volume of business. Even the London District Telegraph Company, which was formed in 1859 for the purpose of transmitting telegraph messages between points in metropolitan London, found that a low uniform rate was not financially practicable. The company began with a tariff of 4d. per 10 words; it soon increased the rate to 6d. for 15 words with an additional porterage charge for delivery beyond a certain distance, and in 1866 the tariff was raised to 1s. The company had 123 m. of line and 83 offices, and in 1865 conveyed over 316,000 messages, but it was not financially successful. Both the telegraph companies and the railway companies had incurred heavy commercial risks in developing the telegraph services of the country and only moderate profits were earned. It cannot justly be said that the companies made large profits while neglecting to develop the services adequately, but it is true that they were not able commercially to comply with many of the demands made upon them by the public. Until speculation took place in anticipation of government purchase, the market prices of the telegraph securities were mostly below par. The stock of the Electric and International Company, the return on which had reached 10 per cent. per annum, however, was valued at about 14 years' purchase of the annual profits. Very little new capital was invested by the telegraph companies about 1865 because of the natural reluctance of the companies to extend the systems under their control so long as a proposal for their acquisition by the state was under consideration. In 1868 the length of electric telegraph lines belonging to the companies was 16,643 m., and of those belonging to the railway companies 4872 m., or a total of 21,515. With regard to the statement that the companies had installed competitive systems and had expended capital needlessly, it was found by the Post Office authorities that in 1865 less than 2000 m. of telegraph lines, and 350 offices out of a total of over 2000, were redundant. The telegraph companies proposed to effect an amalgamation so as to enable the services to be consolidated and extended, and they proposed to submit to various conditions for the protection of the public, such as maximum rates and limitation of dividends, with the provision that new issues of capital should be offered by auction, but public opinion was averse to the proposal. By 1868 both political parties in the House of Commons had committed themselves to the policy of state purchase of the telegraphs.

After much negotiation the basis finally agreed upon between the government and the companies was 20 years' purchase of the profits of the year ended 30th June 1868. The Chancellor of the Exchequer described the terms as "very liberal but not more liberal than they should be under the circumstances," and stated that Mr Scudamore had estimated that £6,000,000 was the maximum price which the government would have to pay, and that the Postmaster-General would obtain from the telegraphs a net annual revenue of £203,000 at least. In addition to the undertakings of the telegraph companies the government had to purchase the reversionary rights of the railway companies which arose out of the circumstance that the telegraph companies for the most part had erected their poles and wires along the permanent way of the railways under leases which in 1868 had still many years to run. The price awarded to the six telegraph companies was £5,733,000. A further £100,000 was paid for the Jersey, Guernsey, Isle of Man and other undertakings, and about £2,000,000 was paid to the railway companies for their reversionary rights, the cost of which had been estimated at £700,000.

The government acquired the perpetual and exclusive wayleaves for telegraph lines over the railways, but the monopoly of the Postmaster-General does not apply to those numerous wires which are required for the protection of life on railways. The telegraphs were transferred to the Post Office on the 5th of February 1870. During the following three years the government spent £500,000 in making good the depreciation suffered by the plant in the transition years of 1868 and 1869, for which allowance had been made in the purchase price, and about £1,700,000 was expended on new plant. During that period 8000 m. of posts, 46,000 m. of wire and about 200 m. of underground pipes were added. The cost of these works had been underestimated, and the report of the Select Committee of the Post Office (Telegraph Department), 1876, states that "the committee have not received any full and satisfactory explanation of the great differences between the estimated expenditure of 1869 and the actual expenditure incurred up to 1876."

The excess expenditure caused the Post Office during two or three years to make temporary application of Savings Banks' balances to telegraph expenditure, an expedient which was disapproved of by both the Treasury and the House of Commons. Probably no more arduous task was ever thrown upon a public department than that imposed on the Post Office by the transfer. The reforms which it was to bring about were eagerly and impatiently demanded by the public. This great operation had to be effected without interrupting the public service, and the department had immediately to reduce and to simplify the charges for transmission throughout the kingdom. It had to extend the hours of business at all the offices; it had to extend the wires from railway stations lying outside of town populations to post offices in the centre of those populations and throughout their suburbs; it had also to extend the wires from towns into rural districts previously devoid of telegraphic communication; it had to effect a complete severance of commercial and domestic telegraphy from that of mere railway traffic, and in order to effect this severance it had to provide the railways with some 6000 m. of wires in substitution for those of which they had been joint users. It had further to provide at low charges for the distribution of news to the Press; it had to facilitate the transmission of money orders by telegram; finally, it had to amalgamate into one staff bodies of men who had formerly worked as rivals upon opposite plans and with different instruments, and to combine the amalgamated telegraph staff with that of the postal service. So zealously was the work of improvement pursued that within little more than six years of the transfer the aggregate extent of road wires in the United Kingdom was already 63,000 m. and that of railway wires 45,000, in all 108,000 m. The number of instruments in the telegraph offices was 12,000. At that date the superintending and managing staffs of the Post Office comprised 590 persons, the staff of the old companies with only about one-third of the traffic having been 534 persons.

The anticipations as to the increase of messages that would result from the reduction of rates were fully realized. The number of messages increased from about 6,500,000 in 1869 to nearly 10,000,000 in 1871 and to 20,000,000 in 1875, but the expectations as to net revenue were not justified by the results. In 1869 Mr Scudamore estimated the operating expenses at 51 to 56 per cent. of the gross revenue. In 1870–1 they were 57 per cent. and in 1871–2, 78 per cent. Since 1873 the capital account has been closed with a total expenditure of £10,867,644, and all subsequent expenditure for extensions, purchase of sites and erection of buildings has been charged against revenue.

There are several reasons for the unsatisfactory financial results apart from the high price paid for the acquisition of the telegraphs. The unprofitable extension of the telegraphs has largely contributed to the loss. Moreover, since 1881 the wages and salaries of the telegraph employees have been increased on several occasions in consequence of political pressure brought to bear on members of parliament; and notwithstanding the protest of the government of the day, the House of Commons in 1883 carried a resolution that the minimum rate for inland telegrams should be reduced to 6d. This involved a large extension of wires to cope with increased traffic. The reduced rate took effect as from the 1st of October 1886.

Another reason assigned by the committee appointed by the Treasury in 1875 "to investigate the causes of the increased cost of the telegraphic service since the acquisition of the telegraphs by the state" is the loss on the business of transmitting Press messages, which has been estimated as at least £300,000 a year. A further cause has been competition offered by the telephone service, but against this the Post Office has received royalties from telephone companies and revenue from trunk telephone lines. These amounted in 1887 to £26,170 and £1312 respectively; in 1897 to £85,289 and £113,294, and in 1907 to £240,331 and £479,639 respectively.

The following table shows the financial results of the business in the year immediately following the purchase of the telegraphs by the state, in the two years preceding and the two years following the introduction of the 6d. tariff, and in the seven financial years from 1900–1907:—

Year.	Number of Messages.	Gross Receipts.	Total Expenditure.	Percentage of Total Expenditure to Gross Receipts.	Net Revenue or Deficiency.	Net Revenue after omitting from Total Expenditure the cost of Sites, Buildings and Telegraph Extensions.	Interest on Stock created for Purchase of Telegraphs.
		£	£		£	£	£

* 5th February 1870.—Transfer of telegraphs to the state.
† 1st October 1885.—Introduction of sixpenny tariff.

Submarine Telegraphs.—The first commercially successful cable was that laid across the straits of Dover from the South Foreland to Sangatte by T. R. Crampton in 1851, and two years later, after several futile attempts, another was laid between Port Patrick in the south of Scotland and Donaghadee in Ireland. This was followed by various other cables between England and the neighbouring countries, and their success naturally revived the idea which had been suggested in 1845 of establishing telegraphic communication between England and America, though this enterprise, on account of the distance and the greater depth of water, was of a much more formidable character. On the American side Cyrus W. Field acquired a concession which had been granted to F. N. Gisborne for a land line connecting St John's, Newfoundland, and Cape Ray, in the Gulf of St Lawrence, and proceeded himself to get control of the points on the American coast most suitable as landing places for a cable. On the British side the question of constructing an Atlantic cable was engaging the attention of the Magnetic Telegraph Company and its engineer Mr (afterwards Sir) Charles Bright. Visiting England in 1856, Field entered into an agreement with Bright and with John Watkins Brett, who with his brother Jacob had proposed the constructing of an Atlantic cable eleven years previously, with the object of forming a company for establishing and working electric telegraphic communication between Newfoundland and Ireland. The Atlantic Telegraph Company was duly registered in 1856, with a capital of £350,000, the great bulk of which was subscribed in England. The manufacture of the cable, begun early in the following year, was finished in June, and before the end of July it was stowed partly in the American ship "Niagara" and partly in the British ship "Agamemnon," both being war-ships lent for the purpose by their respective governments. The shore end was landed in Valentia Harbour on the 5th of August, and next morning paying out was started by the "Niagara," to which the laying of the first half had been entrusted. For the first few days the operation proceeded satisfactorily, though slowly, but on the afternoon of the 11th, when 380 m. had been laid, the cable snapped, owing to a mistake in the manipulation of the brake, and the ships returned to Plymouth with what remained. Next year, 700 m. of new cable having been made, the attempt was renewed, with the same ships, but on this occasion it was decided to begin paying out in mid-ocean, the two vessels, after splicing together the ends of the cable they had on board, sailing away from each other in opposite directions. They left Plymouth on the 10th of June, but owing to a terrific storm it was not till the 25th that they met at the rendezvous. A splice having been made they started on the 26th, but the cable broke almost immediately. Another splice was made, to be followed, after the "Agamemnon" had paid out about 40 m., by another break. Again the ships returned to the rendezvous and made another splice, and again there was a break after the "Agamemnon" had paid out 146 m., and then the "Agamemnon," after again returning to the meeting-place in the vain hope that the "Niagara" might have returned there also, made for Queenstown, where she found her consort had arrived nearly a week previously.

Although a good deal of cable had been lost, enough remained to connect the British and American shores, and accordingly it was determined to make another attempt immediately. To this end the ships sailed from Queenstown on the 17th of July, and having spliced the cable in mid-ocean, started to pay it out on the 29th. The "Niagara" landed her end in Trinity Bay, Newfoundland, on the 5th of August, while on the same day the "Agamemnon" landed hers at Valentia. The electrical condition of the cable was then excellent, but unfortunately the electrician in charge, Wildman Whitehouse, conceived the wrong idea that it should be worked by currents of high potential. For nearly a week futile attempts were made to send messages by his methods, and then a return was made to the weak currents and the mirror galvanometers of Sir William Thomson (Lord Kelvin) which had been employed for testing purposes while the cable was being laid. In this way communication was established from both sides on the 16th of August, but it did not continue long, for the insulation had been ruined by Whitehouse's treatment, and after the 20th of October no signals could be got through.

The next attempt at laying an Atlantic cable was made in 1865, the necessary capital being again raised in England. It was determined that the work should be done by a single ship, and accordingly the "Great Eastern" was chartered. She started from Valentia at the end of July, but fault after fault was discovered in the cable and the final misfortune was that on the 2nd of August, when nearly 1200 m. had been paid out, there was a break, and all the efforts made to pick up the lost portion proved unavailing. Next year the attempt was renewed. The Atlantic Telegraph Company was reconstituted as the Anglo-American Telegraph Company with a capital of £600,000 and sufficient cable was ordered not only to lay a line across the ocean but also to complete the 1865 cable. The "Great Eastern" was again employed, and leaving the south-west coast of Ireland on the 13th of July she reached Trinity Bay a fortnight later, without serious mishap. She then steamed eastwards again, and on the 13th of August made her first attempt to recover the lost cable. This, like many subsequent ones, was a failure, but finally she succeeded on the 2nd of September, and having made a splice completed the laying of the cable on the 8th of September. These two cables did not have a very long life, that of 1865 breaking down in 1877 and that of 1866 in 1872, but by the later of these dates four other cables had been laid across the Atlantic, including one from Brest to Duxbury, Mass. It was stated by Sir Charles Bright in 1887 that by that date 107,000 m. of submarine cable had been laid, while ten years later it was computed that 162,000 nautical miles of cable were in existence, representing a capital of £40,000,000, 75 per cent. of which had been provided by the United Kingdom. Among the men of business it was undoubtedly Sir John Pender (1815–1896) who contributed most to the development of this colossal industry, and to his unfailing faith in their ultimate realization must be ascribed the completion of the first successful Atlantic cables. The submarine cables of the world now have a length exceeding 200,000 nautical miles, and most of them have been manufactured on the Thames.

The monopoly conferred upon the Postmaster-General by the Telegraph Act 1869 was subsequently extended to telephony and wireless telegraphy, but it does not extend to submarine telegraphy. The submarine telegraphs are mainly controlled by companies, the amount of issued capital of the existing British telegraph companies (twenty-four in number) being £30,447,191, but a certain number of lines are in government hands. Thus on the 31st of March 1889 the undertaking of the Submarine Telegraph Company was purchased by the governments concerned. France and Great Britain jointly acquired the cables between Calais and Dover, Boulogne and Folkestone, Dieppe and Beachy Head, Havre and Beachy Head, Piron, near Coutances, and Vieux Châteaux (St Heliers, Jersey). Belgium and Great Britain became joint-proprietors of the cables between Ramsgate and Ostend and Dover and De la Panne (near Furnes). The two cables to Holland and one of the cables to Germany were already the property of Great Britain, and the German Union Company's cable to Germany was purchased by the German government. The offices of the Submarine Company in London, Dover, Ramsgate, East Dean and Jersey were purchased by the Post Office, as well as the cable ship; and the staff, 370 in number, was taken over by the government. The capital amount laid out by Great Britain was £67,163, and on 1st April the new business was begun with a uniform rate to France, Germany, Holland and Belgium of 2d. a word, with a minimum of 10d.

In 1890 Liverpool was placed in direct telegraphic communication with Hamburg and Havre, and London with Rome. The following year an additional cable was laid from Bacton, in Norfolk, to Borkum, in Germany, at the joint expense of the British and German governments. Direct telegraphic communication was thus afforded between London and Vienna. In 1893 a contract was made with the Eastern and South Africa Telegraph Company for the construction, laying and maintenance of a cable from Zanzibar to the Seychelles and Mauritius, a distance of 2210 m., for a subsidy of £28,000 a year for twenty years. In 1894 the Eastern Extension Telegraph Company laid a cable from Singapore to Labuan and Hong Kong, thus duplicating the route and making it an all-British line. The following year the rates to and from East and South Africa were reduced, by negotiation, from charges varying from 7s. 9d. to 8s. 11d. a word to 5s. 2d. or 5s. Government messages were accorded a rate of 2s. 6d., and Press telegrams one of from 1s. 5d. to 1s. 7½d. a word. In 1896 it was arranged to lay two new cables to France and one (for duplex working) to Germany. On the 1st of February 1898 a new cable was laid between Bermuda and Jamaica (via Turks Islands), giving an all-British line to the West Indies, with reduced charges. In 1900 direct telegraph working was established between London and Genoa, and a third cable was laid to South Africa via St Helena and Ascension. In 1896 a committee was appointed to consider the proposal for laying a telegraph cable between British North America and Australasia. The report of the committee, which is dated January 1897, was presented to parliament in April 1899, and dealt with the practicability of the project, the route, the cost and the revenue. The committee was of opinion that the cable should be owned and worked by the governments interested, and that the general direction should be in the hands of a manager in London under the control of a small board at which the associated governments should be represented. The English cable companies urged that state interference with private enterprise was neither justifiable nor necessary, as the rates could be reduced and an alternative cable route to Australia arranged on reasonable terms without it, and that the Cape route would be the best alternative route. The government policy would, they alleged, create an absolute and objectionable monopoly. In the correspondence (*Blue Book*, Ed. 46, 1900) between the Eastern Telegraph Company and the Colonial Office, the company pointed out that Mr Raikes, when Postmaster-General, had stated that "it would be without precedent for the English government itself to become interested in such a scheme in such a way as to constitute itself a competitor with existing commercial enterprises carried on by citizens of the British empire. There would be a very serious question raised, and it would probably extend to other forms of British enterprise." The company further pointed out that Mr L. Courtney (afterwards Lord Courtney), when Secretary of the Treasury, had stated that "it would be highly inexpedient to encourage upon light grounds competition against a company in the position of the Eastern Telegraph Company which has embarked much capital in existing lines"; and that the permanent officials representing the Post Office before the Pacific Cable committee had stated "that there was no precedent for the Imperial Government alone or in association with the Colonies managing or seeking business for a line of this kind." The reply of the Colonial Office contained the following statements of general policy:—"With the progressive development of society the tendency is to enlarge the functions and widen the sphere of action of the central government as well as of the local authorities, and to claim for them a more or less exclusive use of powers, and the performance of services where the desired result is difficult to attain through private enterprise, or where the result of entrusting such powers or services to private enterprise would be detrimental to the public interest, through their being in that event necessarily conducted primarily for the benefit of the undertakers rather than of the public. This tendency is specially manifested in cases where from the magnitude or other conditions of the enterprise the public is deprived of the important safeguard of unrestricted competition. . . . In the case of inland telegraphs and of cable communication with the continent of Europe government control has entirely superseded private companies. Closely analogous to the action of the state in the cases referred to is the action taken by municipal authorities with the authority of the legislature in competing with or superseding private companies for the supply of electric light, gas, water, tramways and other public services. . . . The service which the government and the colonies desire is one which neither the Eastern Telegraph Company nor any other private enterprise is prepared to undertake on terms which can be considered in comparison with the terms upon which it can be provided by the associated governments."

In November 1899 a committee was appointed by the Colonial Office for the further examination of the scheme, and towards the end of 1900 a tender was accepted for the manufacture and laying of a submarine cable between the Island of Vancouver and Queensland and New Zealand for the sum of £1,795,000, the work to be completed by the 31st of December 1902. A board was constituted to supervise the construction and working of the cable, composed of representatives of the several governments, with offices at Westminster. Under the Pacific Cable Act 1901 the capital sum of £2,000,000 was provided in the following proportions:—

United Kingdom, 5/18ths with 3 representatives including the chairman.
Canada, 5/18ths with 2 representatives.
Australia, 6/18ths with 2 representatives.
New Zealand, 2/18ths with 1 representative.

In these proportions the respective contributing governments are responsible for the losses made in the working of the undertaking. The annual expenses of the board include £35,000 for cable repairs and reserve and a fixed payment to the National Debt Commissioners of £77,544 as sinking fund to amortise capital expenditure in fifty years. The deficiency on the working for the year ended 31st March 1907 was £54,924, and the approximate number of messages transmitted during the year was 96,783 with 1,126,940 words. There was in addition a considerable inter-colonial traffic between Australia, New Zealand and the Fijis.

Since the early days of international telegraphy, conferences of representatives of government telegraph departments and companies have been held from time to time (Paris 1865, Vienna 1868, Rome 1871 and 1878, St Petersburg 1875, London 1879, Berlin 1885, Paris 1891, Buda Pesth 1896, London 1903). In 1868 the International Bureau of Telegraphic Administrations was constituted at Berne, and a convention was formulated by which a central office was appointed to collect and publish information and generally to promote the interests of international telegraphy. International service regulations have been drawn up which possess equal authority with the convention and constitute what may be regarded as the law relating to international telegraphy. The total lengths of the land lines of the telegraphs throughout the world in 1907 were 1,015,894 m. aerial, and 11,454 m. underground, and the total lengths of submarine cables of the world were 39,072 nautical miles under government administration and 194,751 nautical miles under the administration of private companies.

PART II.—WIRELESS TELEGRAPHY

The early attempts to achieve electric telegraphy involved the use of a complete metallic circuit, but K. A. Steinheil of Munich, however, acting on a suggestion given by Gauss, made in 1838 the important discovery that half of the circuit might be formed of the conducting earth, and so discovered the use of the *earth return*, since then an essential feature of nearly every telegraphic circuit. Encouraged by this success, he even made the further suggestion that the remaining metallic portion of the circuit might perhaps some day be abolished and a system of wireless telegraphy established.[1]

Morse.

Morse showed, by experiments made in 1842 on a canal at Washington, that it was possible to interrupt the metallic electric circuit in two places and yet retain power of electric communication (see Fahie, *loc. cit.*, p. 10). His plan, which has been imitated by numerous other experimentalists, was as follows:—On each side of the canal, at a considerable distance apart, metal plates *e e* (fig. 35) were sunk in the water; the pair on one side were connected by a battery B, and the pair on the other by a galvanometer or telegraphic receiver R. Under these circumstances a small portion of the current from the battery is shunted through the galvanometer circuit, and can be used to make electric signals. Morse and Gale, who assisted him, found, however, that the distance of the plates up and down the canal must be at least three or four times the width of the canal to obtain successful results. Numerous investigators followed in Morse's footsteps. James Bowman Lindsay of Dundee, between 1845 and 1854, reinvented and even patented Morse's method, and practically put the plan into operation for experimental purposes across the river Tay. J. W. Wilkins in 1849, and H. Highton in experiments described in 1872, also revived the same suggestion for wireless telegraphy.

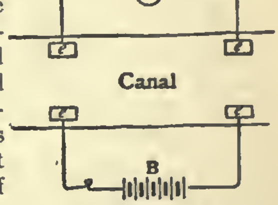

FIG. 35.—Morse's Conduction Method.

Trowbridge.

The invention of the magneto-telephone put into the hands of electricians a new instrument of extraordinary sensitiveness for the detection of feeble interrupted, or alternating, currents, and by its aid J. Trowbridge in 1880, in the United States, made a very elaborate investigation of the propagation of electric currents through the earth, either soil or water (see "The Earth as a Conductor of Electricity," *Amer. Acad. Arts and Sci.*, 1880). He found, as others have done, that if a battery, dynamo or induction coil has its terminals connected to the earth at two distant places, a system of electric currents flows between these points through the crust of the earth. If the current is interrupted or alternating, and if a telephone receiver has its terminals connected to a separate metallic circuit joined by earth plates at two other places to the earth, not on the same equipotential surface of the first circuit, sounds will be heard in the telephone due to a current passing through it. Hence, by inserting a break-and-make key in the circuit of the battery, coil or dynamo, the uniform noise or hum in the telephone can be cut up into periods of long and short noises, which can be made to yield the signals of the Morse alphabet. In this manner Trowbridge showed that signalling might be carried on over considerable distances by electric conduction through the earth or water between places not metallically connected. He also repeated the suggestion which Lindsay had already made that it might be possible to signal in this manner by conduction currents through the Atlantic Ocean from the United States to Europe. He and others also suggested the applicability of the method to the inter-communication of ships at sea. He proposed that one ship should be provided with the means of making an interrupted current in a circuit formed partly of an insulated metallic wire connected with the sea at both ends by plates, and partly of the unlimited ocean. Such an arrangement would distribute a

[1] For a history of the discovery of the earth return, see Fahie, *History of Electric Telegraphy to the Year 1837*, pp. 343–348.

system of flow lines of current through the sea, and these might be detected by any other ships furnished with two plates dipping into the sea at stem and stern, and connected by a wire having a telephone in its circuit, provided that the two plates were not placed on the same equipotential surface of the original current flow lines. Experiments of this kind were actually tried by Graham Bell in 1882, with boats on the Potomac river, and signals were detected at a distance of a mile and a half.

At a later date, 1891, Trowbridge discussed another method of effecting communication at a distance, viz., by means of magnetic induction between two separate and completely insulated circuits. If a primary circuit, consisting of a large coil of wire P (fig. 36), has in circuit a battery B and an interrupter I, and at some distance and parallel to this primary circuit is placed a secondary circuit S, having a telephone T included in it, the interruptions or reversals of the current in the primary circuit will give rise to a varying magnetic field round that circuit which will induce secondary currents in the other circuit and affect the telephone receiver. Willoughby Smith found that it was not necessary even to connect the telephone to a secondary circuit, but that it would be affected and give out sounds merely by being held in the variable magnetic field of a primary circuit. By the use of a key in the battery circuit as well as an interrupter or current reverser, signals can be given by breaking up the continuous hum in the telephone into long and short periods. This method of communication by *magnetic induction* through space establishes, therefore, a second method of wireless telegraphy which is quite independent of and different from that due to *conduction* through earth or water.

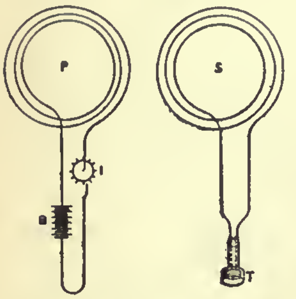

FIG. 36.—Magneto-Induction Method.

Preece.

Sir W. H. Preece, who took up the subject about the same time as Prof. Trowbridge, obtained improved practical results by combining together methods of induction and conduction. His first publication of results was in 1882 (*Brit. Assoc. Report*), when he drew attention to the considerable distance over which inductive effects occurred between parallel wires forming portions of telephonic and telegraphic circuits. Following on this he made an interesting experiment, using Morse's method, to connect the Isle of Wight telegraphically with the mainland, by conduction across the Solent in two places, during a temporary failure of the submarine cable in 1882 in that channel. In subsequent years numerous experiments were carried out by him in various parts of Great Britain, in some cases with circuits earthed at both ends, and in other cases with completely insulated circuits, which showed that conductive effects could be detected at distances of many miles, and also that inductive effects could take place even between circuits separated by solid earth and by considerable distances. A. W. Heaviside in 1887 succeeded in communicating by telephonic speech between the surface of the earth and the subterranean galleries of the Broomhill collieries, 350 feet deep, by laying above and below ground two complete metallic circuits, each about 2½ m. in length and parallel to each other. At a later date other experimentalists found, however, that an equal thickness of sea-water interposed between a primary and secondary circuit completely prevented similar inductive intercommunication. In 1885 Preece and Heaviside proved by experiments made at Newcastle that if two completely insulated circuits of square form, each side being 440 yds., were placed a quarter of a mile apart, telephonic speech was conveyed from one to the other by induction, and signals could be perceived even when they were separated by 1000 yds. The method of induction between insulated primary and secondary circuits laid out flat on the surface of the earth proves to be of limited application, and in his later experiments Preece returned to a method which unites both conduction and induction as the means of affecting one circuit by a current in another. In 1892, on the Bristol Channel, he established communication between Lavernock Point and an island called Flat Holme in that channel by placing at these positions insulated single-wire circuits, earthed at both ends and laid as far as possible parallel to each other, the distance between them being 3·3 m. The shore wire was 1267 yds. long, and that on the island 600 yds. An interrupted current having a frequency of about 400 was used in the primary circuit, and a telephone was employed as a receiver in the secondary circuit. Other experiments in inductive telegraphy were made by Preece, aided by the officials of the British Postal Telegraph Service, in Glamorganshire in 1887; at Loch Ness in Scotland in 1892; on Conway Sands in 1893; and at Frodsham, on the Dee, in 1894. (See *Jour. Inst. Elec. Eng.*, 27, p. 869.) In 1899 experiments were made at Menai Straits to put the lighthouse at the Skerries into communication with the coastguard station at Cemlyn. A wire 750 yds. in length was erected along the Skerries, and on the mainland one of 3½ m. long, starting from a point opposite the Skerries, to Cemlyn. Each line terminated in an earth plate placed in the sea. The average perpendicular distance between the two lines, which are roughly parallel, is 2·8 m. Telephonic speech between these two circuits was found possible and good, the communication between the circuits taking place partly by induction, and no doubt partly by conduction. On the question of how far the effects are due to conduction between the earth plates, and how far to true electromagnetic induction, authorities differ, some being of opinion that the two effects are in operation together. A similar installation of inductive telephony, in which telephone currents in one line were made to create others in a nearly parallel and distant line, was established in 1899 between Rathlin Island on the north coast of Ireland and the mainland. The shortest distance between the two places is 4 m. By stretching on the island and mainland parallel wire circuits earthed at each end, good telephonic communication over an average distance of 6½ m. was established between these independent circuits.

Willoughby Smith.

The difficulty of connecting lightships and isolated lighthouses to the mainland by submarine cables, owing to the destructive action of the tides and waves on rocky coasts on the shore ends, led many inventors to look for a way out of the difficulty by the adoption of some form of inductive or conductive telegraphy not necessitating a continuous cable. Willoughby S. Smith and W. P. Granville put into practice between Alum Bay in the Isle of Wight and the Needles lighthouse a method which depends upon conduction through sea water. (See *Jour. Inst. Elec. Eng.*, 27, p. 938.) It may be explained as follows:—Suppose a battery on shore to have one pole earthed and the other connected to an insulated submarine cable, the distant end of which was also earthed; if now a galvanometer is inserted anywhere in the cable, a current will be found flowing through the cable and returning by various paths through the sea. If we suppose the cable interrupted at any place, and both sides of the gap earthed by connexion to plates, then the same conditions will still hold. Communication was established by this method in the year 1895 with the lighthouse on the Fastnet.[1] A cable is carried out from the mainland at Crookhaven for 7 m., and the outer end earthed by connexion with a copper mushroom anchor. Another earthed cable starts from a similar anchor about 100 ft. away near the shore line of the Fastnet rock, crosses the rock, and is again earthed in the sea at the distant end. If a battery on the mainland is connected through a key with the shore end of the main cable, and a speaking galvanometer is in circuit with the short cable crossing the Fastnet rock, then closing or opening the battery connexion will create a deflection of the galvanometer. A very ingenious call-bell arrangement was devised, capable of responding only to regularly reversed battery currents, but not

[1] See Fahie, *History of Wireless Telegraphy*, p. 170; also 5th Report (1897) of the Royal Commission on Electrical Communication with Lightships and Lighthouses.

to stray "earth currents," and very good signalling was established between the mainland and the rock. Owing to the rough seas sweeping over the Fastnet, the conditions are such that any ordinary submarine cable would be broken by the wearing action of the waves at the rock boundary in a very short time. Another worker in this department of research was C. A. Stevenson, who in 1892 advocated the use of the inductive system pure and simple for communication between the mainland and isolated lighthouses or islands. He proposed to employ two large flat coils of wire laid horizontally on the ground, that on the mainland having in circuit a battery, interrupter and key, and that on the island a telephone. His proposals had special reference to the necessity for connecting a lighthouse on Muckle Flugga, in the Shetlands, and the mainland, but were not carried into effect. Professor E. Rathenau of Berlin made many experiments in 1894 in which, by means of a conductive system of wireless telegraphy, he signalled through 3 m. of water.

Sir Oliver Lodge in 1898 theoretically examined the inductive system of space telegraphy. (See *Jour. Inst. Elec. Eng.*, 27, p. 799.) He advocated and put in practice experimentally a system by which the primary and secondary circuits were "turned" or syntonized by including condensers in the circuits. He proved that when so syntonized the circuits are inductively respondent to each other with a much less power expenditure in the primary circuit than without the syntony. He also devised a "call" or arrangement for actuating an ordinary electric bell by the accumulated effect of the properly tuned inductive impulses falling on the secondary circuit. A very ingenious call-bell or annunciator for use with inductive or conductive systems of wireless telegraphy was invented and described in 1898 by S. Evershed, and has been practically adopted at Lavernock and Flat Holme. (*Id.*, 27, p. 852.)

Lodge.

In addition to the systems of wireless or space telegraphy depending upon conduction through earth or water, and the inductive system based upon the power of a magnetic field created round one circuit to induce, when varied, a secondary current in another circuit, there have been certain attempts to utilize what may best be described as electrostatic induction. In 1885 Edison, in conjunction with Gilliland, Phelps, and W. Smith, worked out a system of communicating between railway stations and moving trains. At each signalling station was erected an insulated metallic surface facing and near to the ordinary telegraph wires. On one or more of the carriages of the trains were placed also insulated metallic sheets, which were in connexion through a telephone and the secondary circuit of an induction coil with the earth or rails. In the primary circuit of the induction coil was an arrangement for rapidly intermitting the current and a key for short-circuiting this primary circuit. The telephone used was Edison's chalk cylinder or electromotograph type of telephone. Hence, when the coil at one fixed station was in action it generated high frequency alternating currents, which were propagated across the air gap between the ordinary telegraph wires and the metallic surfaces attached to one secondary terminal of the induction coil, and conveyed along the ordinary telegraph wires between station and moving train. Thus, in the case of one station and one moving railway carriage, there is a circuit consisting partly of the earth, partly of the ordinary telegraph wires at the side of the track, and partly of the circuits of the telephone receiver at one place and the secondary of the induction coil at the other, two air gaps existing in this circuit. The electromotive force of the coil is, however, great enough to create in these air gaps displacement currents which are of magnitude sufficient to be equivalent to the conduction current required to actuate a telephone. This current may be taken to be of the order of two or three micro-amperes. The signals were sent by cutting up the continuous hum in the telephone into long and short periods in accordance with the Morse code by manipulating the key in the primary circuit. The system was put into practical operation in 1887 on the Lehigh Valley railroad in the United States, and worked well, but was abandoned because it apparently fulfilled no real public want. Edison also patented (U.S.A. *Pat. Spec.*, No. 465971, 14th May 1885) a plan for establishing at distant places two insulated elevated plates. One of these was to be connected to the earth through a telephone receiver, and the other through the secondary circuit of an induction coil in the primary circuit of which was a key. The idea was that variations of the primary current would create electromotive force in the secondary circuit which would act through the air condenser formed by the two plates. It has sometimes been claimed that Edison's proposed elevated plates anticipated the subsequent invention by Marconi of the aerial wire or antenna, but it is particularly to be noticed that Edison employed no spark gap or means for creating electrical high frequency oscillations in these wires. There is no evidence that this plan of Edison's was practically operative as a system of telegraphy.

Edison.

A very similar system of wireless telegraphy was patented by Professor A. E. Dolbear in 1886 (U.S.A. *Pat. Spec.*, No. 350299), in which he proposed to employ two batteries at two places to affect the potential of the earth at those places. At the sending station one battery was to have its positive pole connected to the earth and its negative pole to an insulated condenser. In circuit with this battery was placed the secondary circuit of an induction coil, the primary circuit of which contained a telephone transmitter or microphone interrupter. At the receiving station a telephone receiver was placed in series with another insulated battery, the negative terminal of which was to be in connexion with the earth. There is no evidence, however, that the method proposed could or did effect the transmission of speech or signals between stations separated by any distance. Many other more or less imperfect devices—such as those of Mahlon Loomis, put forward in 1872 and 1877, and Kitsee in 1895—for wireless telegraphy were not within the region of practically realizable schemes.

Space or Radio-Telegraphy by Hertzian Waves.—Up to 1895 or 1896 the suggestions for wireless telegraphy which had been publicly announced or tried can thus be classified under three or four divisions, based respectively upon electrical conduction through the soil or sea, magnetic induction through space, combinations of the two foregoing, and lastly, electrostatic induction. All these older methods have, however, been thrown into the background and rendered antiquated by inventions which have grown out of Hertz's scientific investigations on the production of electric waves. Before the classical researches of Hertz in 1886 and 1887, many observers had noticed curious effects due to electric sparks produced at a distance which were commonly ascribed to ordinary electrostatic or electro-magnetic induction. Thus Joseph Henry (*Scientific Writings*, vol. i. p. 203) noticed that a single electric spark about an inch long thrown on to a circuit of wire in an upper room could magnetize steel needles included in a parallel circuit of wire placed in a cellar 30 ft. below with two floors intervening. Some curious distance-phenomena connected with electric sparks were observed in 1875 by Edison (who referred them to a supposed new "aetheric force"), and confirmed by Beard, S. P. Thompson, E. J. Houston and others.[1] D. E Hughes made some remarkable observations and experiments in or between the years 1879 and 1886 though he did not describe them till some twenty years afterwards. He discovered a fact subsequently rediscovered by others, that a tube of metallic filings, loosely packed, was sensitive to electric sparks made in its vicinity, its electrical resistance being reduced, and he was able to detect effects on such a tube connected to a battery and telephone at a distance of 500 yds.[2]

These distance effects were not understood at the time, or else were referred simply to ordinary induction. Hertz, however, made known in 1887 the experimental proofs that the discharge

[1] See *Telegraphic Journal of London*, vol. iv. pp. 29, 46, 61; *Proc. Phys. Soc. Lond.*, vol. ii. p. 103.

[2] See Fahie, *History of Wireless Telegraphy*, p. 289; also an important letter by D. E. Hughes in *The Electrician*, London, 1899, 43, 40.

of a condenser produces an electric spark which under proper conditions creates an effect propagated out into space as an *electric wave*. He employed as a detector of this wave a simple, nearly closed circuit of wire called a Hertz resonator, but it was subsequently discovered that the metallic microphone of D. E. Hughes was a far more sensitive detector. The peculiar action of electric sparks and waves in reducing the resistance of discontinuous conductors was rediscovered and investigated by Calzecchi Onesti,[1] by Branly,[2] Dawson Turner,[3] Minchin, Lodge,[4] and many others. Branly was the first to investigate and describe in 1890 the fact that an electric spark at a distance had the power of changing loose aggregations of metallic powders from poor to good electric conductors, and he also found that in some cases the reverse action was produced. Lodge particularly studied the action of electric waves in reducing the resistance of the contact between two metallic surfaces such as a plate and a point, or two balls, and named the device a "coherer." He constructed one form of his coherer of a glass tube a few inches long filled with iron borings or brass filings, having contact plates or pins at the end. When such a tube is inserted in series with a single voltaic cell and galvanometer it is found that the resistance of the tube is nearly infinite, provided the filings are not too tightly squeezed. On creating an electric spark or wave in the neighbourhood of the tube the resistance suddenly falls to a few ohms and the cell sends a current through it. By shaking or tapping the tube the original high resistance is restored. In 1894 he exhibited apparatus of this kind in which the tapping back of the tube of filings was effected automatically. He ascribed the reduction of resistance of the mass to a welding or cohering action taking place between the metallic particles, hence the name "coherer." But, as Branly showed, it is not universally true that the action of an electric wave is to reduce the resistance of a tube of powdered metal or cause the particles to cohere. In some cases, such as that of peroxide of lead, an increase of resistance takes place.

Between 1894 and 1896 G. Marconi gave great attention to the improvement of devices for the detection of electric waves.

Marconi. He made his sensitive tube, or improved coherer, as follows:—A glass tube having an internal diameter of about 4 millimetres has sealed into it two silver plugs PP by means of platinum wires WW (fig. 37); the opposed faces of these plugs are perfectly smooth, and are placed within a millimetre of each other. The interspace is filled with a very small quantity of nickel and silver filings, about 95 per cent. nickel and 5 per cent. silver, sufficient to fill loosely about half the cavity between the plugs, which fit tightly into the tube.[5] The tube is then exhausted of its air, and attached to a bone or glass rod as a holder. This form of electric wave detector proved itself to be far more certain in operation and sensitive

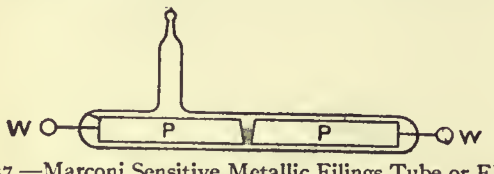

Fig. 37.—Marconi Sensitive Metallic Filings Tube or Electric Wave Detector.

than anything previously invented. The object which Marconi had in view was not merely the detection of electric waves, but their utilization in practical wireless telegraphy. Sir William Crookes had already suggested in 1892 in the *Fortnightly Review* (February 1892) that such an application might be made, but no one had overcome the practical difficulties or actually shown how to do it.

G. Marconi, however, made the important discovery that if his sensitive tube or coherer had one terminal attached to a metal plate lying on the earth, or buried in it, and the other to an insulated plate elevated at a height above the ground, it could detect the presence of very feeble electric waves of a certain kind originating at a great distance. In conjunction with the above receiver he employed a transmitter, which consisted of a large induction or spark coil S having its spark balls placed a few millimetres apart; one of these balls was connected to an earth

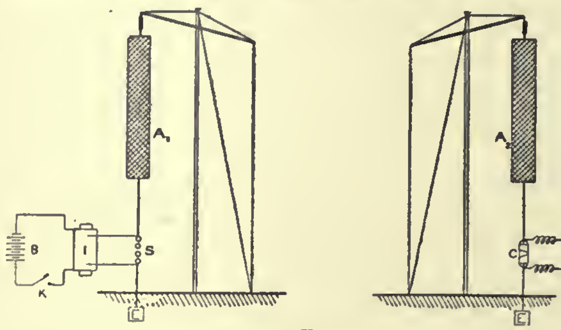

Fig. 38.

plate E and the other to a plate or wire insulated at the upper end and elevated above the surface of the earth. In the primary circuit of the induction coil I he placed an ordinary signalling key K, and when this was pressed for a longer or shorter time a torrent of electric sparks passed between the balls, alternately charging and discharging the elevated conductor A_1 and creating electrical oscillations (see Electro-Kinetics) in the wire. This elevated conductor is now called the *antenna*, *aerial wire*, or *air wire*. At the receiving station Marconi connected a single voltaic cell B_1 and a sensitive telegraphic relay R in series with his tube of metallic filings C, and interposed certain little coils called choking coils. The relay was employed to actuate through a local battery B_2 an ordinary Morse printing telegraphic instrument M. One end of the sensitive tube was then connected to the earth and the other end to an antenna or insulated elevated conductor A_2. Assuming the transmitting and receiving apparatus to be set up at distant stations (see fig. 38[6]), the insulated wires or plates being upheld by masts, its operation is as follows:—When the key in the primary circuit of the induction coil is pressed the transmitting antenna wire is alternately charged to a high potential and discharged with the production of high frequency oscillations in it. This process creates in the space around electric waves or periodic changes in electric and magnetic force round the antenna wire. The antenna wire, connected to one spark ball of the induction coil, must be considered to form with the earth, connected to the other spark ball, a condenser. Before the spark happens lines of electrostatic force stretch from one to the other in curved lines. When the discharge takes place the ends of the lines of electric force abutting on the wire run down it and are detached in the form of semi-loops of electric force which move outwards with their ends on the surface of the earth. As they travel they are accompanied by lines of magnetic force, which expand outwards in ever-widening circles.[7] The magnetic and electric forces are directed alternately in one direction and the other, and at distances which are called multiples of a *wave length* the force is in the same direction at the same time, but in the case of damped waves has not quite the same intensity. The force at any one point also varies cyclically, that is, is varying at any one point

[7] For a more complete account of the nature of an electric wave the reader is referred to Hertz's *Electric Waves*, and to the article Electric Wave. See also *The Principles of Electric Wave Telegraphy*, by J. A. Fleming.

and varying from point to point. This periodic distribution in time and space constitutes an electric wave proceeding outwards in all directions from the sending antenna. If we consider the lines of magnetic force in the neighbourhood of the receiving antenna wire we shall see that they move across it, and thus create in it an electromotive force which acts upon the coherer or other sensitive device associated with it.

Marconi's System of Wireless Telegraphy.—Marconi's system of electric wave telegraphy consists therefore in setting up at the transmitting station the devices just described for sending out groups of damped electric waves of the above kind in long or short trains corresponding to the *dash* or *dot* signals of the Morse alphabet. These trains are produced by pressing the key in the primary circuit of the induction coil for a longer or shorter time and generating a long or short series of oscillatory electric sparks between the spark balls with a corresponding creation of trains of electric waves. At the receiving station he connected, as stated, one end of the sensitive tube to earth and the other to the antenna, and improved and applied a device of Popoff for automatically tapping the tube after each electric impact had rendered it conductive. He caused the relay in series with the sensitive tube to set in action not only a telegraphic instrument but also the electromagnetic tapper, which was arranged so as to administer light blows on the under side of the sensitive tube when the latter passed into the conductive condition. The effect was to print a *dash* or *dot* on a strip of telegraphic paper, according as the incident electric wave train lasted a longer or shorter time. In addition he added certain spark-generating coils across the contacts of the relay and tapper. He thus produced in 1896 for the first time an operative apparatus of electric wave telegraphy. Its simplicity and compactness recommended it immediately for communication between ship and shore and for intermarine communication generally. Marconi's earliest experiments with this apparatus were made in Italy. In 1896 he came to England and gave demonstrations to the British postal telegraph department and other officials. Some of these experiments were made on Salisbury Plain and others in the Bristol Channel between Lavernock and Flat Holm and Bream Down in 1897. Early in 1898 permanent stations were established between Alum Bay and Bournemouth, a distance of 14½ m., where successful results were obtained. Later the Bournemouth station was removed to Poole Harbour, and the Alum Bay station to Niton in the Isle of Wight, the distance being thus increased to 30 m. In December 1898 communication was established by the Marconi method between the East Goodwin lightship and the South Foreland lighthouse; and this installation was maintained for upwards of a year, during which it was the means of saving both life and property. In March 1899 communication was effected by his system between England (South Foreland lighthouse) and France (Wimereux, near Boulogne), a distance of 30 m. He kept up the communication for six months, in all weathers, and found that ordinary commercial messages could be transmitted at the rate of 15 to 20 words a minute. In January 1901 he established communication by his system between the Lizard in Cornwall and Niton in the Isle of Wight, a distance of 200 m. A full account of the development of his system was given by him in an article published in the *Fortnightly Review* for June 1902; see also a paper by him in the *Journ. Inst. Elec. Eng.*, 1899, 28, p. 273. About this time he introduced various improvements into the receiving apparatus. Instead of inserting the sensitive tube between the receiving antenna and the earth, he inserted the primary coil of a peculiar form of oscillation transformer and connected the terminals of the tube to the secondary circuit of the transformer. Lodge had previously suggested the use of transformed oscillations for acting on the coherer (see *British Patent Spec.*, No. 11575 of 1897), but it is not every form of oscillation transformer which is suitable for this purpose.

Marconi's successes and the demonstrations he had given of the thoroughly practical character of this system of electric wave telegraphy stimulated other inventors to enter the same field of labour, whilst theorists began to study carefully the nature of the physical operations involved. It was seen that the effect of the impact of the incident electric waves upon the vertical receiving wire was to create in it electrical oscillations, or in other words, high frequency alternating electric currents, such that whilst the potential variations were a maximum at the top or insulated end of the antenna the current at that point was zero and at the base the potential variation was zero and the current amplitude a maximum. Hence devices for detecting the oscillations in the antenna are merely very sensitive forms of ammeter and voltmeter. It was also recognized that what is required at the transmitting end is the establishment of powerful electric oscillations in the sending antenna, which create and radiate their energy in the form of electric waves having their magnetic force component parallel to the earth's surface and their electric component perpendicular to it.

Transmitting Apparatus.—We now consider the more recent appliances for electric wave telegraphy under the two divisions of transmitting and receiving apparatus. First as regards the transmitting part, one essential element is the *antenna, aerial*, or *air wire*, which may take a variety of forms. It may consist of a single plain or stranded copper wire upheld at the top by an insulator from a mast, chimney or building. The wire may have at the upper end a plate called a "capacity area," electrically equivalent to an extension of the wire, or part of the wire may be bent over and carried horizontally. In many cases multiple antennae are used consisting of many wires arranged in cone or umbrella-rib fashion, or a metal roof or metallic chimney may be employed (see fig. 39). In any case the antenna serves as one surface of a condenser, the other surface of which is the earth. This condenser is charged electrically and then suddenly discharged and violent electrical oscillations are set up in it, that is to say, electricity rushes to and fro between the antenna and the earth. This creates rapid variations in electric and magnetic force round the antenna and detaches energy from it in the form of an electric wave. The antenna has at one moment a static electrical charge distributed upon it, and lines of electric force stretch from it to the surrounding earth. At the next instant it is the seat of an electric current and is surrounded by closed lines of magnetic force. These static and kinetic conditions succeed each other rapidly, and the result is to detach or throw off from the antenna semi-loops of electric force, which move outwards in all directions and are accompanied by expanding circular lines of magnetic force. The whole process is exactly analogous to

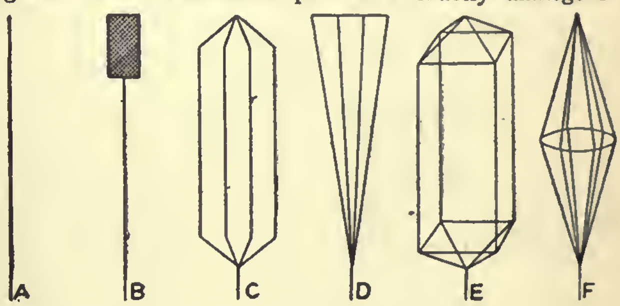

FIG. 39.

the operation by which a violin string or organ pipe creates an air or sound wave. The violin string is first drawn on one side. This strain corresponds to the electrical charging of the antenna. The string is then suddenly released. This corresponds to the electrical discharge of the antenna, and the subsequent string vibrations to the electrical vibrations. These communicate their energy to the surrounding air, and this energy is conveyed away in the form of air waves.

There are three ways in which the antenna may be charged:—

(i) It may be separated from the earth by a pair of spark balls which are connected respectively to the terminals of an induction coil or transformer, or other high tension generator. If these spark balls are set at the right distance, then when the potential difference accumulates the antenna will be charged and at some stage suddenly discharged by the discharge leaping across the spark gap. This was Marconi's original method, and the plan is still used under the name of the direct method of excitation or the plain antenna.

(ii) The antenna may have oscillations excited in it inductively. F. Braun suggested in 1898 that the oscillatory discharge of a Leyden jar should be sent through the primary coil of a transformer and the secondary coil should be interposed between the antenna and an earth connexion.[1] Marconi[2] imparted practical utility to this idea by tuning the two circuits together, and the arrangement now employed is as follows:— A suitable condenser C, or battery of Leyden jars, has one coating connected to one spark ball and the other through a coil of one turn with the other spark ball of a discharger S. These spark balls are connected either to the secondary circuit of an induction coil I, or to that of an alternating current transformer having a secondary voltage of 20,000 to 100,000 volts. Over the coil of one turn is wound a secondary circuit of 5 or 10 turns, of which one end is connected to the earth through a variable inductance and the other end to an antenna or radiating wire A (see fig. 40). These two circuits are so adjusted that the *closed* oscillation circuit, consisting of the condenser, primary coil

[1] See *German Patent* of F. Braun, No. 11578 of 1898, or *British Specification*, No. 1862 of 1899.

[2] See *British Pat. Spec.*, G. Marconi, No. 7777 of 1900.

and spark gap, has the same natural time period of oscillation as the *open* circuit consisting of the antenna, secondary coil and adjustable inductance. When this is the case, if discharges are made across the spark gap oscillations are excited in the closed circuit, and these induce other syntonic oscillations in the antenna circuit. J. A. Fleming devised an arrangement in which a multiple transformation takes place, two oscillation circuits being interlinked inductively, and the last one acting inductively on the open or antenna circuit. J. S. Stone similarly devised a multiple inductive oscillation circuit with the object of forcing on the antenna circuit a single oscillation of definite frequency.[1] In the case of the inductive mode of exciting the oscillations an important quantity is the *coefficient of coupling* of the two oscillation circuits. If L and N are the inductances of any two circuits which have a coefficient of mutual inductance M, then $M/\surd(LN)$ is called the coefficient of coupling of the circuits and is generally expressed as a percentage. Two circuits are said to be closely coupled when this coefficient is near unity and to be loosely coupled if it is very small. It can be shown that if two circuits, both having capacity (C) and inductance (L), are coupled together inductively, then, when oscillations are set up in one circuit, oscillations of two periods are excited in the other differing in frequency from each other and from the natural frequency of the circuit. If the two circuits are in tune so that the numerical product of capacity and inductance of each circuit is the same or $C_1L_1 = C_2L_2 + CL$ and if k is the coefficient of coupling then the natural frequency of each circuit is $n = 1/2\pi\surd(CL)$, and when coupled two oscillations are set up in the secondary circuit having frequencies n_1 and n_2 such that $n_1 = n/\surd(1-k)$ and $n_2 = n/\surd(1+k)$. Since in all cases of

FIG. 40.

wave motion the wave-length λ is connected with the frequency n and the velocity of propagation v by the relation $v = n\lambda$, it follows that from such an inductively coupled tuned antenna electric waves of two wave-lengths are sent out having lengths λ_1 and λ_2 such that $\lambda_1 = \lambda\surd(1-k)$ and $\lambda_2 = \lambda\surd(1+k)$, where λ is the natural wave-length. It is seen that as the coupling k becomes small these two wave-lengths coalesce into one single wave length. Hence there are advantages in employing a very loose coupling.

(iii) The antenna may be direct-coupled to the closed oscillatory circuit in the manner suggested by F. Braun, A. Slaby and O. Lodge. In this case a closed condenser circuit is formed with a battery of Leyden jars, an inductance coil and a spark gap, and oscillations are excited in it by discharges created across the spark gap by an induction coil or transformer. One end of the inductance coil is connected to the earth, and some other point on the closed condenser circuit to an antenna of appropriate length. When oscillations are created in the closed circuit syntonic oscillations are created in the antenna and electric waves radiated from it (fig. 41). In many cases additional condensers or inductance coils are inserted in various places so that the arrangement is somewhat disguised, but by far the larger part of the electric wave wireless telegraphy in 1907 was effected by transmitters having antennae either inductively or directly coupled to a closed condenser circuit containing a spark gap.

In practical wireless telegraphy the antenna is generally a collection of wires in fan shape upheld from one or more masts or wooden towers. Sometimes the prolongations of these wires are carried horizontally or dipped down so as to form an umbrella antenna (fig. 42). The lower ends of these wires are connected through the secondary coil of an oscillation transformer to an earth plate, or to a large conductor placed on or near the earth called a "balancing capacity." If the direct coupling is adopted then the lower end of the antenna is connected directly to the condenser circuit. The main capacity in this last circuit consists of a battery of Leyden jars or of Leyden panes immersed in oil or some form of air condenser, and the inductance coil or primary circuit of the oscillation transformer consists of a few turns of highly insulated wire wound on a frame and immersed in oil. The oscillations are controlled either by a key inserted in the primary circuit of the exciting induction coil or transformer, or by a key cutting in and out of the primary condensers or throwing inductance in and out of the closed oscillation circuit. In one of these ways the oscillations can be created or stopped at pleasure in the radiating antenna, and hence groups of electric waves thrown off at will.

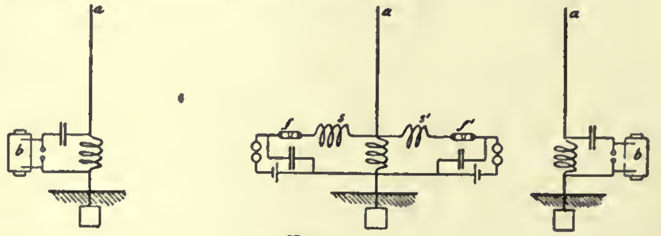

FIG. 41.

Production of Electric Waves of Large Amplitude.—In creating powerful electric waves for communication over long distances it is necessary to employ an alternating current transformer (see TRANSFORMERS) supplied with alternating currents from a low frequency alternator D driven by an engine to charge the condenser (fig. 43). The transformer T_1 has its secondary or high-pressure terminals connected to spark balls S_1, which are also connected by a circuit consisting of a large glass plate condenser C_1 and the primary circuit of an air-core transformer T_2, called an oscillation transformer. The secondary circuit of this last is either connected between an aerial A and the earth E, or it may be again in turn connected to a second pair of spark balls S_2, and these again to a second condenser C_2, oscillation transformer T_2, and the aerial A. In order to produce electric oscillations in the system, the first or alternating current transformer must charge the condenser connected to its secondary terminals, but must not produce a permanent electric arc between the balls. Various devices have been suggested for extinguishing the arc and yet allowing the condenser oscillatory discharge to take place. Tesla effected this purpose by placing the spark balls transversely in a powerful magnetic field. Elihu Thomson blows on the spark balls with a powerful jet of air. Marconi causes the spark balls to move rapidly past each other or causes a studded disk to move between the spark balls. J. A. Fleming devised a method which has practical advantages in both preventing the arc and permitting the oscillatory currents to be controlled so as to make electric wave signals. He inserts in the primary circuit of the alternating

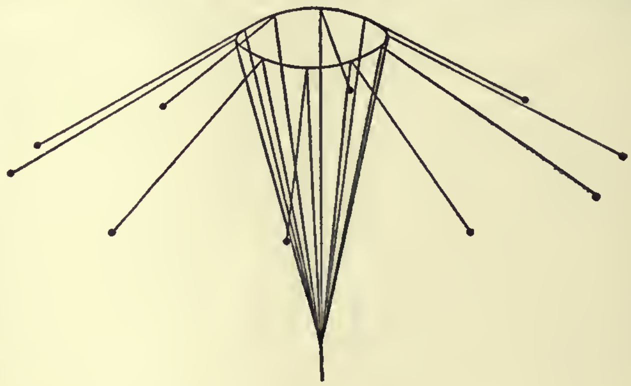

FIG. 42.

current transformers one or more choking or impedance coils R_1, R_2 (fig. 43), called "chokers," which are capable, one or all, of being short-circuited by keys K_1, K_2. The impedance of the primary or alternator circuit is so adjusted that when both the chokers are in circuit the current flowing is not sufficient to charge the condensers; but when one choker is short-circuited the impedance is reduced so that the condenser is charged, but the alternating arc is not formed. In addition it is necessary to

[1] See J. S. Stone, *U.S.A. Pat. Spec.*, Nos. 714756 and 714831.

adjust the frequency so that it has the value of the normal time period of the circuit formed of the condenser and transformer secondary circuit, and thus it is possible to obtain condenser oscillatory discharges free from any admixture with alternating current arc. In this manner the condenser discharge can be started or stopped at pleasure, and long and short discharges made in accordance with the signals of the Morse

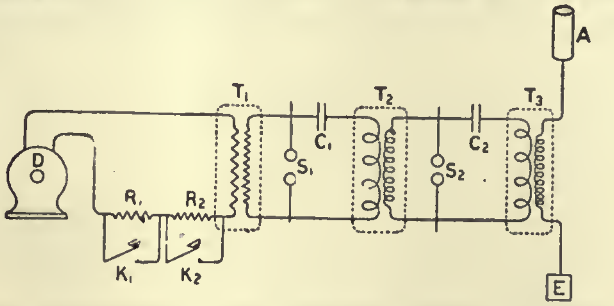

FIG. 43.—Alternate Current Transformer System. (Fleming.)

alphabet by manipulating the short-circuiting key of one of the choking coils (see *British Patent Specs.*, Nos. 18865, 20576 and 22126 of 1900, and 3481 of 1901).

In the case of transmitters constructed as above described, in which the effective agent in producing the electric waves radiated is the sudden discharge of a condenser, it should be noticed that what is really sent out is a train of damped or decadent electric waves. When electric oscillations are set up in an open or closed electric circuit having capacity and inductance, and left to themselves, they die away in amplitude, either because they dissipate their energy as heat in overcoming the *resistance* of the circuit, or because they *radiate* it by imparting wave motion to the surrounding ether. In both cases the amplitude of the oscillations decreases more or less rapidly. Such a sequence of decreasing electric oscillations and corresponding set of waves is called a damped train. In the case of the plain or directly excited antenna the oscillations are highly damped, and each train probably only consists at most of half a dozen oscillations. The reason for this is that the capacity of a simple antenna is very small—it may be something of the order of 0·0002 of a microfarad—and hence the energy stored up in it even under a high voltage is also small. Accordingly this energy is rapidly dissipated and but few oscillations can take place. If, however, the antenna is inductively or directly coupled to a condenser circuit of large capacity then the amount of energy which can be stored up before discharge takes place is very much greater, and hence can be drawn upon to create prolonged or slightly damped trains of waves. Allusion is made below to recent work on the production of undamped trains of electric waves.

Receiving Arrangements.—Before explaining the advantages of such small damping it will be necessary to consider the usual forms of the receiving appliance. This consists of a receiving antenna similar to the sending antenna, and in any wireless telegraph station it is usual to make the one and the same antenna do duty as a receiver or sender by switching it over from one apparatus to the other. The electric waves coming through space from the sending station strike against the receiving antenna and set up in it high frequency alternating electromotive forces. To detect these currents some device has to be inserted in the antenna circuit or else inductively connected with it which is sensitive to high frequency currents. These wave-detecting devices may be divided into two classes: (i) potential operated detectors, and (ii) current operated detectors. The oldest of the class (i) is that generically known as a *coherer*, the construction of which we have already described. The ordinary forms of metallic filings coherer of the Branly type require tapping to bring them back to the high resistance or sensitive condition. Lodge arranged a mechanical tapper for the purpose which continually administered the small blow to the tube sufficient to keep the filings in a sensitive condition. Popoff employed an electromagnetic tapper, in fact the mechanism of an electric bell with the gong removed, for this purpose. Marconi, by giving great attention to details, improved the electromagnetic tapper, and, combining it with his improved form of sensitive tube, made a telegraphic instrument as follows: the small glass tube, containing nickel and silver filings between two silver plugs, was attached to a bone holder, and under this was arranged a small electromagnet having a vibrating armature like an electric bell carrying on it a stem and hammer. This hammer is arranged so that when the armature vibrates it gives little blows to the underside of the tube and shakes up the filings. By means of several adjusting screws the force and frequency of these blows can be exactly regulated. In series with the tube is placed a single voltaic cell and a telegraphic relay, and Marconi added certain coils placed across the spark contacts of the relay to prevent the local sparks affecting the coherer. The relay itself served to actuate a Morse printing telegraph by means of a local battery. This receiving apparatus, with the exception of the Morse printer, was contained in a sheet-iron box, so as to exclude it from the action of the sparks of the neighbouring transmitter. In the early experiments Marconi connected the sensitive tube in between the receiving antenna and the earth plate, but, as already mentioned, in subsequent forms of apparatus he introduced the primary coil of a peculiar form of oscillation transformer into the antenna circuit and connected the ends of the sensitive tube to the terminals of the secondary circuit of this "jigger" (fig. 44). In later improvements the secondary circuit of this jigger was interrupted by a small condenser, and the terminals of the relay and local cell were connected to the plates of this condenser, whilst the sensitive tube was attached to the outer ends of the secondary circuit. Also another condenser was added in parallel with the sensitive tube.

With this apparatus some of Marconi's earliest successes, such as telegraphing across the English Channel, were achieved, and telegraphic communication at the rate of fifteen words or so a minute established between the East Goodwin lightship and the South Foreland lighthouse, also between the Isle of Wight and the Lizard in Cornwall. It was found to be peculiarly adapted for communication between ships at sea and between ship and shore, and a system of regular supermarine communication was put into operation by two limited companies, Marconi's Wireless Telegraph Company and the Marconi International Marine Communication Company. Stations were established on various coast positions and ships supplied with the above-described apparatus to communicate with each other and with these stations. By the end of 1901 this radio-telegraphy had been established by Marconi and his associates on a secure industrial basis.

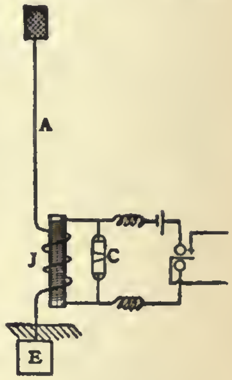

FIG. 44.

Various Forms of Wave Detectors or Receivers.—The numerous adjustments required by the tapper and the inertia of the apparatus prompted inventors to seek for a self-restoring coherer which should not need tapping. Castelli, a petty officer in the Italian navy, found that, if a small drop of mercury was contained in a glass tube between a plug of iron and carbon, with certain adjustments, the arrangement was non-conductive to the current from a single cell but became conductive when electric oscillations passed through it.[1] Hence the following appliance was worked out by Lieutenant Solari and officers in the Italian navy.[2] The tube provided with certain screw adjustments had a single cell and a telephone placed in series with it, and one end of the tube was connected to the earth and the other end to a receiving antenna. It was then found that when electric waves fell on the antenna a sound was heard in the telephone as each wave train passed over it, so that if the wave trains endured for a longer or shorter time the sound in the telephone was of corresponding duration. In this manner it was possible to hear a Morse code dash or dot in the telephone. This method of receiving soon came to be known as the telephonic method. Lodge, Muirhead and Robinson also devised a self-restoring coherer as follows:[3]—A small steel wheel with a sharp edge was kept rotating by clockwork so that its edge continually cut through a globule of mercury covered with paraffin oil. The oil film prevented

[1] See *Electrical Review*, 1902, 51, p. 968.

[2] See "A Royal Institution Discourse," by G. Marconi, *The Electrician*, 1902, 49, p. 490; also *British Pat. Spec.*, No. 18105 of 1901.

[3] See *British Pat. Spec.*, Lodge and others, No. 13521 of 1902.

perfect electrical contact between the steel and mercury for low voltage currents, but when electric oscillations were passed through the junction it was pierced and good electrical contact established as long as the oscillations continued. This device was converted into an electric wave detector as follows:—The mercury-steel junction was acted upon by the electromotive force of a shunted single cell and a siphon recorder was inserted in series. The wheel was connected to a receiving antenna and the mercury to earth or to an equivalent balancing capacity. When electric waves fell on the antenna they caused the mercury-steel junction to become conductive during the time they endured, and the siphon recorder therefore to write signals consisting of short or long deflexions of its pen and therefore notches of various length on the ink line drawn on the strip of telegraphic tape.

An innumerable number of forms of coherer or wave detector depending upon the change in resistance produced at a loose or imperfect contact have been devised. A. Popoff,[1] E. Branly,[2] A. Blondel,[3] O. Lodge[4] and J. A. Fleming[5] invented special forms of the metallic contact or metallic filings sensitive tube. Brown and Neilson,[6] F. J. Jervis-Smith[7] and T. Tommasina[8] tried carbon in various forms. The theory of the action of the coherer has occupied the attention of T. Sundorp,[9] T. Tommasina,[8] K. E. Guthe,[10] J. C. Bose,[11] W. H. Eccles,[12] and Schäfer.[13] For details see J. A. Fleming, *The Principles of Electric Wave Telegraphy and Telephony*, p. 416, 2nd ed. 1910.

The next class of wave or oscillation detector is the magnetic detector depending upon the power of electric oscillations to affect the magnetic state of iron. It had long been known that the discharges from a Leyden jar could magnetize or demagnetize steel needles. J. Henry in the United States in 1842 and 1850 investigated the effect. In 1895 E. Rutherford examined it very carefully, and produced a magnetic detector for electric waves depending upon the power of electric oscillations in a coil to demagnetize a saturated bundle of steel wires placed in it (see *Phil. Trans.*, 1897, 189 A, p. 1). Rutherford used this detector to make evident the passage of an electric or Hertzian wave for half a mile across Cambridge, England. In 1897 E. Wilson constructed various forms of electric wave detector depending on this same principle. In 1902 Marconi invented two forms of magnetic detector, one of which he developed into an electric wave detector of extraordinary delicacy and utility (see *Proc. Roy. Soc.*, 1902, 70, p. 341, or *British Pat. Spec.*, No. 10245 of 1902). In this last form an endless band of hard iron wires passes slowly round two wooden pulleys driven by clockwork. In its course it passes through a glass tube wound over with two coils of wire; one of these is an oscillation coil through which the oscillations to be detected pass, and the other is in connexion with a telephone. Two horse-shoe magnets are so placed (fig. 45) that they magnetize the part of the iron band passing through the coil. Owing to hysteresis the part of the band magnetized is not symmetrically placed with regard to the magnetic poles, but advanced in the direction of motion of the band. When the oscillations pass through the coil they annul the hysteresis and cause a change of magnetism within the coil connected to the telephone. This creates a short sound in the telephone. Hence according as the trains of oscillations are long or short so is the sound heard in the telephone, and these sounds can be arranged on the Morse code into alphabetic audible signals. When used as a receiver for wireless telegraphy Marconi inserted the oscillation coil of this detector in between the earth and a receiving antenna, and this produced one of the most sensitive receivers yet made for wireless telegraphy. Other forms of magnetic detector have been devised by J. A. Fleming,[14] L. H. Walter and J. A. Ewing,[15] H. T. Simon and M. Reich,[16] R. A. Fessenden[17] and others.

A third class of electric wave detector depends upon the power of electric oscillations to annul the electrolytic polarization of electrodes of small surface immersed in an electrolyte. If in a vessel of nitric acid are placed a large platinum plate and a platinum electrode of very small surface such as that produced when an extremely fine platinum wire is slightly immersed in the liquid, and if a current from a single voltaic cell is passed through the electrolytic cell so that the fine wire is the anode or positive pole, then the small surface will be polarized or covered with a film of gas due to electrolysis (fig. 46). This increases the resistance of the electrolytic cell. If, however, one electrode of this cell is connected to the earth and the other to a receiving antenna and electric waves allowed to fall on the antenna, the oscillations passing through the electrolytic cell will remove the polarization and temporarily decrease the resistance of the cell. This may be detected by putting a telephone in series with the electrolytic cell, and then on the impact of the electric waves a sound is heard in the telephone due to the sudden increase in the current through it. Such receivers were devised by R. A. Fessenden,[18] W. Schloemilch[19] and others, and are known as electrolytic detectors. Discussions have taken place as to the theory of the operations in them, in which some have advocated a thermal explanation and others a chemical explanation (see V. Rothmund and A. Lessing, *Ann. der Physik*, 1904, 15, p. 193, and J. E. Ives, *Electrical World* of New York, December 1904).

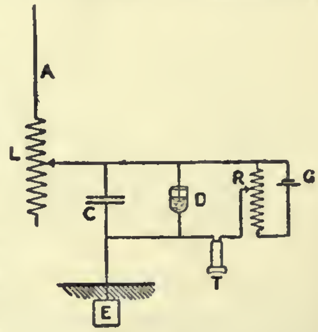

FIG. 46.

A fourth class of electric wave detector comprises the thermal detectors which operate in virtue of the fact that electric oscillations create heat in a fine wire through which they pass. One form such a detector takes is the *bolometer*. If a loop of very fine platinum wire, prepared by the Wollaston process, is included in an exhausted glass bulb like an incandescent lamp, then when electric oscillations are sent through it its resistance is increased. This increase may be made evident by making the loop of wire one arm of a Wheatstone's bridge and so arranging the circuits that the oscillations pass through the fine wire. H. Rubens and Ritter in 1890 (*Wied. Ann.*, 1890, 40, p. 56) employed an arrangement as follows: Four fine platinum or iron wires were joined in lozenge shape, and two sets of these R and S were connected up with two resistances P and Q to form a bridge with a galvanometer G and battery B. To one of these sets of fine wires an antenna A and earth connexion E is added (fig. 47) and when electric waves fall on A they excite oscillations in the fine wire resistance R and increase the resistance, and so upset the balance of the bridge and cause the galvanometer to deflect. Such a bolometer receiver has been used by C. Tissot (*Comptes rendus*, 1904, 137, p. 846) and others as a receiver in electric wave telegraphy.

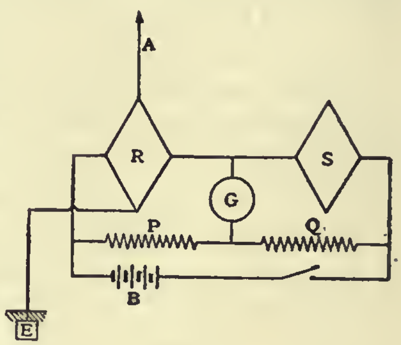

FIG. 47.

Fessenden employed a simple fine loop of Wollaston platinum wire in series with a telephone and shunted voltaic cell, so that when electric oscillations passed through the fine wire its resistance was increased and the current through the telephone suddenly diminished (R. A. Fessenden, *U.S.A. Pat. Spec.*, No. 706742 and No. 706744 of 1902). I. Klemençiç devised a form of thermal receiver depending on thermoelectricity. A pair of fine wires of iron and constantan are twisted together in the middle, and one pair of unlike ends are connected to a galvanometer. If then oscillations are sent through the other pair heat is produced at the junction and the galvanometer indicates a thermoelectric current (*Wied. Ann.*, 1892, 45, p. 78). This thermoelectric receiver was made vastly more sensitive by W. Duddell (*Phil. Mag.*, 1904, 8, p. 91). He passed the oscillations to be detected through a fine wire or strip of gold leaf, and over this, but just not touching, suspended a loop of bismuth-antimony wire by a quartz fibre. This loop hung in a very strong magnetic field, and when one junction was heated by radiation and convection from the heating wire the loop was

[18] See R. A. Fessenden, *U.S.A. Pat. Spec.*, No. 731029, and reissue No. 12115 of 1903.

traversed by a current and deflected in the field. Its deflexion was observed by an attached mirror in the usual way.

Another form of thermoelectric receiver has been devised by J. A. Fleming (*Phil. Mag.*, December 1906) as follows:—It consists of two glass vessels like test tubes one inside the other, the space between the two being exhausted. Down the inner test tube pass four copper strips having platinum wires at their ends sealed through the glass. In the inner space between the test tubes one pair of these platinum wires are connected by a fine constantan wire about ·02 mm. in diameter. The other pair of platinum wires are connected by a tellurium-bismuth thermo-couple, the junction of which just makes contact with the centre of the fine wire. The outer terminals of this junction are connected to a galvanometer, and when electric oscillations are sent through the fine wire they cause a deflexion of this galvanometer (fig. 48). The thermal detectors are especially useful for the purpose of quantitative measurements, because they indicate the true effective or square root of mean square value of the current or train of oscillations passing through the hot wire. On the other hand, the coherer or loose contact detectors are chiefly affected by the initial value of the electromotive force acting on the junction during the train of oscillations, and the magnetic detectors by the initial value of the current and also to a considerable extent by the number of oscillations during the train. Hence the coherer type of detectors are called potential detectors whilst the thermal are called integral current detectors, the current detectors depending entirely or to some extent upon the damping of the train of oscillations, that is to say, upon the number of oscillations forming a train.

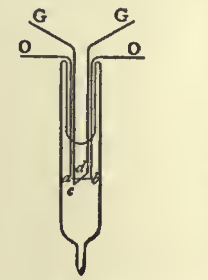

FIG. 48.—Tellurium-bismuth Vacuum Thermal Detector for Electric Oscillations. *a b*, constantan wire; *c d*, thermojunction; G G, galvanometer terminals; O O, antenna and earth terminals.

The fifth type of wave detector depends upon the peculiar property of rarefied gases or vapours which under some circumstances possess a unilateral conductivity. Thus J. A. Fleming invented in 1904 a detector called an oscillation valve or glow lamp detector made as follows:[1] A small carbon filament incandescent lamp has a platinum plate or cylinder placed in it surrounding or close to the filament. This plate is supported by a platinum wire sealed through the glass. Fleming discovered that if the filament is made incandescent by the current from an insulated battery there is a unilateral conductivity of the rarefied gas between the hot filament and the metal plate, such that if the negative terminal of the filament is connected outside the lamp through a coil in which electric oscillations are created with the platinum plate, only one half of the oscillations are permitted to pass, viz., those which carry negative electricity from the hot filament to the cooled plate through the vacuous space. This phenomenon is connected with the fact that incandescent bodies, especially in rarefied gases, throw off or emit electrons or gaseous negative ions.

Such an oscillation valve was first used by Fleming as a receiver for wireless telegraph purposes in 1904 as follows:—In between the receiving antenna and the earth is placed the primary coil of an oscillation transformer; the secondary circuit of this transformer contains a galvanometer in series with it, and the two together are joined between the external negative terminal of the carbon filament of the above-described lamp and the insulated platinum plate. When this is the case oscillations set up in the antenna will cause a continuous current to flow through the galvanometer, the lamp acting as a valve to stop all those electric oscillations in one direction and only permit the opposite ones to pass (fig. 49). Wehnelt discovered that the same effect could be produced by using instead of a carbon filament a platinum wire covered with the oxides of calcium or barium, which when incandescent have the property of copiously emitting negative ions. Another form of receiver can be made depending on the properties of mercury vapour. A highly insulated tube contains a little mercury, which is used as a negative electrode, and the tube also has sealed through the glass a platinum wire carrying an iron plate as an anode. A battery with a sufficient number of cells is connected to these two electrodes so as to pass a current through the mercury vapour, negative electricity proceeding from the mercury cathode to the iron anode. The mercury vapour then possesses a unilateral conductivity, and can be used to filter off all those oscillations in a train which pass in one direction and make them readable on an ordinary galvanometer. In addition to the above gaseous rectifiers of oscillations it has been found that several crystals, such as carborundum (carbide of silicon), hessite, anastase and many others possess a unilateral conductivity and enable us to rectify trains of oscillations into continuous currents which can affect a telephone. Also several contacts, such as that of galena (sulphide of lead) and plumbago, and molybdenite and copper possess similar powers, and can be used as detectors in radio-telegraphy. See G. W. Pierce, *The Physical Review*, July 1907, March 1909, on crystal rectifiers for electric oscillations.

Syntonic Electric Wave Telegraphy.—If a simple receiving antenna as above described is set up with an oscillation-detecting device attached to it, we find that it responds to incident electric waves of almost any frequency or damping provided that the magnetic force of the wave is perpendicular to the antenna, and of sufficient intensity. This arrangement is called a non-syntonic receiver. On the other hand, if a closed oscillation circuit is constructed having capacity and considerable inductance, then oscillations can be set up in it by very small periodic electromotive forces provided these have a frequency exactly agreeing with that of the condenser circuit. This last circuit has a natural frequency of its own which is numerically measured by $1/2\pi\sqrt{(CL)}$, where C is the capacity of the condenser and L is the inductance of the circuit. The problem of syntonic electric wave telegraphy is then to construct a transmitter and a receiver of such kind that the receiver will be affected by the waves emitted by the corresponding or syntonic transmitter, but not by waves of any other wave-length or by irregular electric impulses due to atmospheric electricity. It was found that to achieve this result the transmitter must be so constructed as to send out prolonged trains of slightly damped waves. Electric-radiative circuits like thermal radiators are divided into two broad classes, good radiators and bad radiators. The good electric radiators may be compared with good thermal radiators, such as a vessel coated with lamp black on the outside, and the bad electric radiators to poor thermal radiators, such as a silver vessel highly polished on its exterior. When electric oscillations are set up in these two classes of electric radiators, the first class send out a highly damped wave train and the second a feeble damped wave train provided that they have sufficient capacity or energy storage and low resistance. A radiator of this last class can be constructed by connecting inductively or directly an antenna of suitable capacity and inductance to a nearly closed electric circuit consisting of a condenser of large capacity, a spark gap and an inductance of low resistance. When oscillations are excited in this last circuit they communicate them to the antenna provided this last circuit is *tuned* or syntonized to the closed circuit, and the radiating antenna has thus a large store of energy to draw upon and can therefore radiate prolonged trains of electric waves. The above statements, though correct as far as they go, are an imperfect account of the nature of the radiation from a coupled antenna, but a mathematical treatment is required for a fuller explanation.

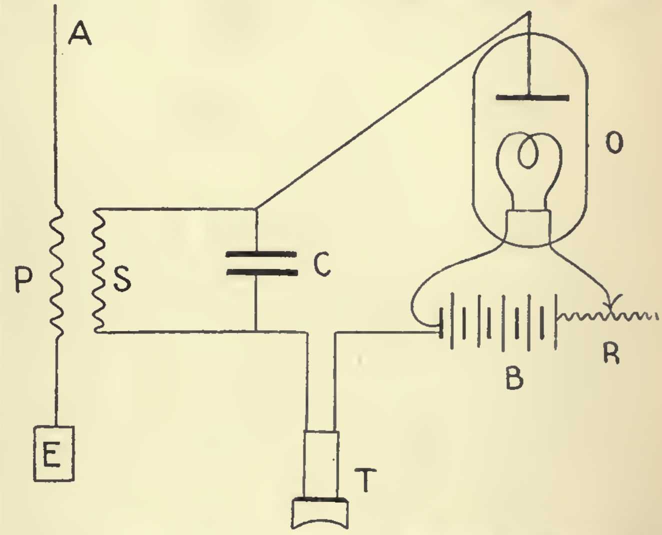

FIG. 49.—A, antenna; P S, jigger or oscillation transformer; C, condenser; O, Fleming oscillation valve; B, working battery; T, telephone; R, rheostat; E, earth-plate.

The success so far achieved in isolating electric wave telegraphic stations has been based upon the principles of electric resonance and the fact that electric oscillations can be set up in a circuit having capacity and considerable inductance by feeble electromotive impulses, provided they are of exactly the natural frequency of the said circuit. We may illustrate the matter as follows: A heavy pendulum possesses inertia and the property of being displaced from a position of rest but tending to return to it. These mechanical qualities correspond to inductance and capacity in electric circuits. Such a pendulum can be set in vigorous vibration even by feeble puffs of air directed against it, provided these are administered exactly in time with the natural period of vibration of the pendulum.

Although inventors had more or less clearly grasped these principles they were first embodied in practice in 1900 by G. Marconi in an operative system of syntonic wireless telegraphy. His transmitter consists of a nearly closed oscillating circuit comprising a condenser or battery of Leyden jars, a spark gap, and the primary coil of an oscillation transformer consisting of one turn of thick wire wound on a wooden frame. Over this primary is wound a secondary circuit of five to ten turns which has one end connected to the earth through a variable inductance coil and the other end to an antenna. These two circuits are syntonized so that the closed or condenser circuit and the open or antenna circuit are adjusted to have, when separate, the same natural electrical time of vibration. The receiving arrangement consists of an antenna which is connected to earth through the primary coil of an oscillation transformer and a variable inductance. The secondary circuit of this transformer is cut in the middle and has a condenser inserted in it, and its ends are connected to the sensitive metallic filings tube or coherer as shown in fig. 50. This receiver therefore, like the transmitter,

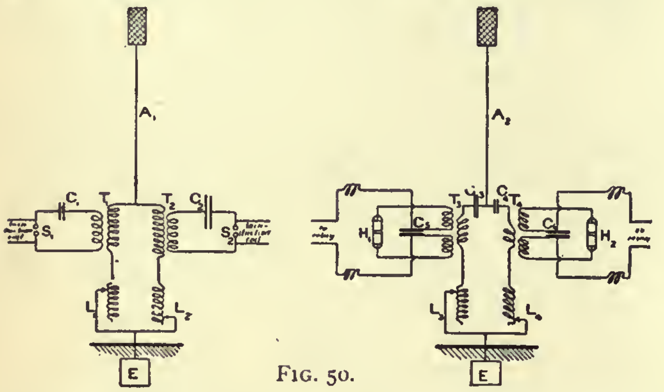

Fig. 50.

consists of an open and a closed electric oscillation circuit inductively connected together; also the two circuits of the receiver must be syntonized or tuned both to each other and to those of the transmitter.[1] When this is done we have a syntonic system which is not easily affected by electric waves of other than the right period or approximating thereto. Marconi exhibited in October 1900 this apparatus in action, and showed that two or more receivers of different tunes could be connected to the same antenna and made to respond separately and simultaneously to the action of separate but tuned transmitters.

A. Slaby in Berlin shortly afterwards made a similar exhibition of syntonic electric wave telegraphy.[2] O. Lodge had previously described in 1897 a syntonic system of electric wave telegraphy, but it had not been publicly seen in operation prior to the exhibitions of Marconi and Slaby.[3] Lodge was, however, fully aware that it was necessary for syntonic telegraphy to provide a radiator capable of emitting sustained trains of waves. His proposed radiator and absorber consisted of two wing-shaped plates of copper, the transmitter plates being interrupted in the centre by a spark gap, and the receiver plates by an inductance coil from the ends of which connexions were made to a coherer. At a later date a syntonic system comprising, as above stated, an antenna directly coupled to a resonant closed circuit was put into operation by Lodge and Muirhead, and much the same methods have been followed in the system known as the *Telefunken* system employed in Germany.

A method of syntonic telegraphy proposed by A. Blondel (*Comptes rendus*, 1900, 130, p. 1383) consisted in creating a syntony not between the frequency of the oscillations in the sender and receiver circuits but between the groups of oscillations constituting the wave trains; but, although other patentees have suggested the same plan, the author is not aware that any success has attended its use in practice. The only other suggested solution of the problem of isolation in connexion with wireless telegraph stations was given by Anders Bull (*Electrician*, 1901, 46, p. 573). Very briefly stated, his method consists in sending out a group of wave trains at certain irregular but assigned intervals of time to constitute the simplest signal equivalent to a dot in the Morse code, and a sequence of such trains, say three following one another, to constitute the dash on the Morse code. The apparatus is exceedingly complicated and can only be understood by reference to very detailed diagrams. (See *Principles of Electric Wave Telegraphy*, by J. A. Fleming, 1906, sect. 13, chap. viii.) By means of the Anders Bull apparatus several messages can be sent out simultaneously from different transmitters and received independently and simultaneously upon corresponding receivers, while no ordinary non-syntonic or other receiver is able either to obscure the messages being sent to the Anders Bull receivers or to interpret those that may be picked up. Although complicated the apparatus seems to work fairly well.

Practical Electric Wave Telegraphy.—At this stage it may be convenient to outline the progress of electric wave telegraphy since 1899. Marconi's success in bridging the English Channel at Easter in 1899 with electric waves and establishing practical wireless telegraphy between ships and the shore by this means drew public attention to the value of the new means of communication. Many investigators were thus attracted into this field of research and invention. In Germany A. Slaby and F. Braun were the most active. Slaby paid considerable attention to the study of the phenomena connected with the production of the oscillations in the antenna. He showed that in a simple Marconi antenna the variations of potential are a maximum at the insulated top and a minimum at the base, whilst the current amplitudes are a maximum at the top earthed end and zero at the top end. He therefore saw that it was a mistake to insert a potential-affected detector such as a coherer in between the base of the antenna and the earth because it was then subject to very small variations of potential between its ends. He overcame the difficulty by erecting a vertical earthed receiving antenna like a lightning rod and attached a lateral extension to it at a yard or two above the earthed end. To the outer end of this lateral wire a condenser was attached and the coherer inserted between the condenser and the earth. The oscillations set up in the vertical antenna excited sympathetic ones in the lateral circuit provided this was of the proper length; and the coherer was acted upon by the maximum potential variations possible. Passing over numerous intermediate stages of development we find that in 1898 Professor F. Braun showed that oscillations suitable for the purposes of electric wave creation in wireless telegraphy could be set up in a circuit consisting of a Leyden jar or jars, a spark gap and an inductive circuit, and communicated to an antenna either by inductive or direct coupling (*Brit. Pat. Spec.*, No. 1862 of 1899). When the methods for effecting this had been worked out practically it finally led to the inventions of Slaby, Braun and others being united into a system called the Telefunken system, which, as regards the transmitter, consisted in forming a closed oscillation circuit comprising a condenser, spark gap and inductance which at one point was attached either directly or through a condenser to the earth or to an equivalent balancing capacity, and at some other point to a suitably tuned antenna. The receiving arrangements comprised also an open or antenna circuit connected directly with a closed condenser-inductance circuit, but in place of the spark gap in the transmitter an electrolytic receiver was inserted, having in connexion with it as indicator a voltaic cell and telephone. In this manner the signals are read by ear. In the same way the arrangements finally elaborated by Lodge and Muirhead consisted of a direct coupled antenna and nearly closed condenser circuit, and a similar receiving circuit containing as a detector the steel wheel revolving on oily mercury which actuated a siphon recorder writing signals on paper tape. Arrangements not very different in general principle were put into practice in the United States by Fessenden, de Forest and others.

Hence it will be seen that the difference between various forms of the so-called spark systems of wireless telegraphy is not very

[1] See G. Marconi, *Brit. Pat. Spec.*, No. 7777 of 1900; also *Journ. Soc. Arts*, 1901, 49, p. 505.

[3] See O. Lodge, *Brit. Pat. Spec.*, No. 11575 of 1897.

great. All of them make use of Marconi's antenna in some form both at the transmitting and at the receiving end, all of them make use of an earth connexion, or its equivalent in the form of a balancing capacity or large surface having capacity with respect to the earth, which merely means that they insert a condenser of large capacity in the earth connexion. All of them couple the transmitting antenna directly or inductively to a capacity-inductive circuit serving as a storage of energy, and all of them create thereby electric waves of the same type moving over the earth's surface with the magnetic force of the wave parallel to it. At the receiving station the differences in these systems depend chiefly upon variations in the actual form of the oscillation detector used, whether it be a loose contact or a thermal, electrolytic or magnetic detector.

In July and August 1899 the Marconi system of wireless telegraphy was tried for the first time during British naval manoeuvres, and the two cruisers, "Juno" and "Europa," were fitted with the new means of communication. The important results obtained showed that a weapon of great power had been provided for assisting naval warfare. From and after that time the British Admiralty and the navies of other countries began to give great attention to the development of electric wave telegraphy.

Transatlantic Wireless Telegraphy.—Having found that the principles of resonance could be successfully applied so as to isolate wireless telegraph receivers, Marconi turned his attention to the accomplishment of his great ambition, viz. Transatlantic wireless telegraphy. In January 1901 he telegraphed without difficulty by electric waves from the Isle of Wight to the Lizard, viz. 200 m., and he considered that the time had come for a serious attempt to be made to communicate across the Atlantic. A site for a first Transatlantic electric wave power station was secured at Poldhu, near Mullion in south Cornwall, by the Marconi Company, and plans arranged for an installation. Up to that time an induction coil known as a 10-inch coil had sufficed for spark production, but it was evident that much more power would be required to send electric waves across the Atlantic. Transformers were therefore employed taking alternating electric current from an alternator driven by an oil or steam engine, and these high tension transformers were used to charge condensers and set up powerful oscillations in a multiple antenna. The special electrical engineering arrangements employed at the outset for this first electric wave power station required to create the oscillations of the desired power were designed for Marconi by J. A. Fleming, but the arrangements were subsequently altered and improved by Marconi, one of the most important additions being a form of high-speed rotating disk discharger devised by Marconi by which he was able to immensely increase the speed of signalling. The first antenna employed consisted of 50 bare copper wires 200 ft. long, arranged in fan-shape and upheld between two masts. Subsequently this antenna was enlarged, and four wooden lattice towers were built, 215 ft. high and 200 ft. apart, sustaining a conical antenna comprised of 400 wires (see G. Marconi, *Proc. Roy. Inst.*, 1902, 17, p. 208). This transmitting plant was completed in December 1901, and Marconi then crossed the Atlantic to Newfoundland and began to make experiments to ascertain if he could detect the waves emitted by it. At St John's in Newfoundland he erected a temporary receiving antenna consisting of a wire 400 ft. long upheld by a box kite, and, employing a sensitive coherer and telephone as a receiver, he was able, on December 12, 1901, to hear "S" signals on the Morse code, consisting of three dots, which he had arranged should be sent out from Poldhu at stated hours, according to a preconcerted programme, so as to leave no doubt they were electric wave signals sent across the Atlantic and not accidental atmospheric electric disturbances. This result created a great sensation, and proved that Transatlantic electric wave telegraphy was quite feasible and not inhibited by distance, or by the earth's curvature even over an arc of a great circle 3000 m. in length. In a repetition of this experiment at the end of February 1902 Marconi, on board the s.s. "Philadelphia," received wireless messages printed on the ordinary Morse tape at a distance of 1557 m. from the sending station at Poldhu, and also received the letter "S" at a distance of 2099 m. from the same place. In the course of this voyage he noticed that the signals were received better during the night than the daytime, legible messages being received on a Morse printer only 700 m. by day but 1500 by night.

The appliances in the Poldhu station were subsequently enlarged and improved by Marconi, and corresponding power stations erected at Cape Cod, Massachusetts, U.S.A., and at Cape Breton in Nova Scotia. In 1902 Marconi was able to transmit a large number of messages across the Atlantic, receiving them by means of his magnetic detector. In the same year numerous experiments were tried with the assistance of an Italian battleship, the "Carlo Alberto," lent by the Italian government, and messages were transmitted from Poldhu to Kronstadt, to Spezia, and also to Sydney in Nova Scotia. Doubts having been raised whether the powerful electric waves sent out from these stations would not interfere with the ordinary ship to shore communication, special demonstrations were made by Marconi before the writer, and later before British naval officers, to demonstrate that this was not the case.[1] In 1904 a regular system of communication of press news and private messages from the Poldhu and Cape Breton stations to Atlantic liners in mid-Atlantic was inaugurated, and daily newspapers were thenceforth printed on board these vessels, news being supplied to them daily by electric wave telegraphy. By the middle of 1905 a very large number of vessels had been equipped with the Marconi short distance and long distance wireless telegraph apparatus for intercommunication and reception of messages from power stations on both sides of the Atlantic, and the chief navies of the world had adopted the apparatus. In 1904, during the Russo-Japanese war, war news was transmitted for *The Times* by wireless telegraphy, the enormous importance of which in naval strategy was abundantly demonstrated.

As the power station at Poldhu was then fully occupied with the business of long distance transmission to ships, the Marconi Company began to erect another large power station to Marconi's designs, at Clifden in Connemara on the west coast of Ireland. This station was intended for the Transatlantic service in correspondence with a similar station at Glace Bay in Nova Scotia. It was completed in the summer of 1907, and on the 17th of October 1907 press messages and private messages were sent across the Atlantic in both directions. The station was opened shortly afterwards for public service, the rates being greatly below that then current for the cable service.

The service was, however, interrupted in August 1909 by a fire, which destroyed part of the Glace Bay station, but was re-established in April 1910.

Meanwhile other competitors were not idle. The inventions of Slaby, Braun and others were put into practice by a German wireless telegraph company, and very much work done in erecting land stations and equipping ships. In France the scientific study of the subject was advanced by the work of Blondel, Tissot, Ducretet and others, and systems called the Ducretet and Rochefort set in operation. In the United States the most active workers and patentees at this period were R. A. Fessenden, Lee de Forest, J. S. Stone, H. Shoemaker and a few others. In England, in addition to the Marconi Company, the Lodge-Muirhead Syndicate was formed to operate the inventions of Sir Oliver Lodge and Dr Muirhead.

Directive Telegraphy.—A problem of great importance in connexion with electric wave telegraphy is that of limiting the radiation to certain directions. A vertical transmitting antenna sends out its waves equally in all directions, and these can be equally detected by a suitable syntonic or other receiver at all points on the circumference of a circle described round the transmitter. This, however, is a disadvantage. What is required is some means for localizing and directing a beam of radiation. The first attempts involved the use of mirrors. Hertz had shown that the electric radiation from an oscillator

[1] See J. A. Fleming, *The Principles of Electric Wave Telegraphy* (London, 1906), chap. vii.; also Cantor Lectures on Hertzian wave telegraphy, Lecture iv., *Journ. Soc. Arts*, 1903, or letter to *The Times*, April 14, 1903.

could be reflected and converged by cylindrical parabolic mirrors. He operated with electric waves two or three feet in wave-length. Experiments precisely analogous to optical ones can be performed with somewhat shorter waves. Marconi in his first British patent (No. 12039 of 1896) brought forward the idea of focusing a beam of electric radiation for telegraphic purposes on a distant station by means of parabolic mirrors, and tried this method successfully on Salisbury Plain up to a distance of about a couple of miles. As, however, the wave-length necessary to cover any considerable distance must be at least 200 or 300 ft., it becomes impracticable to employ mirrors for reflection. The process of reflection in the case of a wave motion involves the condition that the wave-length shall be small compared with the dimensions of the mirror, and hence the attempt to reflect and converge electric waves 1000 ft. in length by any mirrors which can be practically constructed would be like attempting optical experiments with mirrors one-hundred-thousandth of an inch in diameter.

Another closely connected problem is that of locating or ascertaining the direction of the sending station. To deal with the latter question first, one of the earliest suggestions was that of J. S. Stone (*U.S.A. Pat. Spec.*, Nos. 716134 and 716135, also reissue No. 12148), who proposed to place two receiving antennae at a distance of half a wave-length apart. If these two were broadside on to the direction of the sending station oscillations in the same phase would be produced in them both, but if they were in line with it then the oscillations would be in opposite phases. It was then proposed to arrange a detector so that it was affected by the algebraic sum of the two oscillations, and by swivelling round the double receiving antennae to locate the direction of the sending station by finding out when the detector gave the best signal. Even if the proposal had been practicable with waves 1000 or 2000 ft. in length, which it is not, it is essentially based upon the supposition that the damping of the waves is negligible. A proposal was made by L. de Forest (*U.S.A. Pat. Spec.*, No. 771818) to employ a receiving antenna consisting of vertical wires held in a frame which could be swivelled round into various positions and used to locate the position of the sending station by ascertaining the position in which the frame must be placed to create in it the maximum oscillatory current. Other inventors had professed to find a solution of the problem by the use of looped receiving antennae or antennae inclined in various directions.

G. Marconi, however, gave in 1906 the first really practical solution of the problem by the use of bent transmitting and receiving antennae. He showed that if an antenna were constructed with a short part of its length vertical and the greater part horizontal, the lower end of the vertical part being earthed, and if oscillations were created in it, electric waves were sent out most powerfully in the plane of the antenna and in the direction opposite to that in which the free end pointed. Also he showed that if such an antenna had its horizontal part swivelled round into various directions the current created in a distant receiver antenna varied with the azimuth, and when plotted out in the form of a polar curve gave a curve of a peculiar figure-of-8 shape.[1] The mathematical theory of this antenna was given by J. A. Fleming (*Proc. Roy. Soc.*, May 1906, also *Phil. Mag.*, December 1906). Marconi also showed that if such a bent receiving antenna was used the greatest oscillations were created in it when its insulated end pointed directly away from the sending station. In this manner he was able to provide means for locating an invisible sending station. F. Braun also gave an interesting solution of the problem of directive telegraphy.[2] In his method three vertical antennae are employed, placed at equidistant distances, and oscillations are created in the three with a certain relative difference of phase. The radiations interfere in an optical sense of the word, and in some directions reinforce each other and in other directions neutralize each other, so making the resultant radiation greater in some directions than others. Very valuable work in devising forms of antennae for directive radio-telegraphy has been done by MM. Bellini and Tosi, who have devised instruments, called radiogonimeters, for projecting radiation in required directions and locating the azimuth of a transmitting station.

Improvements in the Production of Continuous Trains of Electric Waves.—All the above-described apparatus employed in connexion with wireless telegraph transmitters, in which the oscillatory discharge of a condenser is used to create oscillations in an antenna, labours under the disadvantage that the time occupied by the oscillations is a very small fraction of the total time of actuation. Thus, for instance, when using an induction coil or transformer to charge a condenser, it is not generally convenient to make more than 50 discharges per second, but each of these may create a train of oscillations consisting of, say, 20 to 50 waves. Supposing, then, that these waves are 1000 ft. in wave-length, the frequency of the oscillations would by 1,000,000 per second, and accordingly 50 of these waves would be emitted in 1/20,000th part of a second; and if there are 50 groups of waves per second, the total time occupied by the oscillations in a second would only be 1/400th part of a second. In other words, the intervals of silence are nearly 400 times as long as the intervals of activity. It very soon, therefore, became clear to inventors that a very great advantage would be gained if some means could be discovered of creating high frequency oscillations which were not intermittent but continuous. The condenser method of making oscillations is analogous to the production of air vibrations by twanging a harp string at short intervals. What is required, however, is something analogous to an organ pipe which produces a continuous sound.

A method of producing these oscillations devised by Valdemar Poulsen is based upon the employment of what is called a musical arc. W. Duddell discovered in 1900 that if a continuous current carbon arc had its carbon electrodes connected by a condenser in series with an inductance, then under certain conditions oscillations were excited in this condenser circuit which appeared to be continuous. Poulsen immensely improved this process by placing the arc in an atmosphere of hydrogen, coal-gas or some other non-oxidizing gas, and at the same time arranging it in a strong magnetic field.[3] In this way he was able to produce an apparatus which created continuous trains of oscillations suitable for the purposes of wireless telegraphy. The so-called musical arc of Duddell has been the subject of considerable investigation, and physicists are not entirely in accordance as to the true explanation of the mode of production of the oscillations. It appears, however, to depend upon the fact that an electric arc is not like a solid conductor. Increase in the voltage acting upon a solid conductor increases the current through it, but in the case of the electric arc an increase in current is accompanied by a fall in the difference of potential of the carbons, within certain limits, and the arc has therefore been said to possess a negative resistance.[4]

Poulsen's method of producing continuous or undamped electrical waves has been applied by him in radio-telegraphy. The electric arc is formed between cooled copper (positive) and carbon (negative) electrodes in an atmosphere of hydrogen or coal-gas. In recent apparatus, to enable it to be used on board ship, a hydrogeneous spirit is used which is fed drop by drop into the chamber in which the arc is worked. Across the arc is a transverse or radial magnetic field, and the electrodes are connected by an oscillatory circuit consisting of a condenser and inductance. The antenna is connected either directively or inductively with the circuit. At the receiving end are a similar antenna and resonant circuit, and a telephone is connected across one part of the latter through an automatic interrupting device called by Poulsen a "ticker." To send signals the continuous or nearly continuous train of waves must be cut up into Morse signals by a key, and these are then heard as audible signals in the telephone. An important modification of this method enables not only audible signals but articulated words to be transmitted, and gives thus a system of wireless telephony. This has been achieved by employing a microphone transmitter at the sending end to vary the amplitude but not the wave-length of the emitted waves, and at the receiving end using an electrolytic receiver, which proves to be not merely a qualitative but also a quantitative instrument, to make these variations audible on a telephone. The system has already been put into practice in Germany by the *Gesellschaft für drahtlose Telegraphie*, and in the United States by R. A. Fessenden. This last-named inventor has

employed for the production of the continuous trains of waves a high frequency alternator of his own invention (see *The Electrician*, 1907, 58, pp. 675, 701). Much work has been done on this matter by E. Ruhmer, for which the reader must be referred to his work, *Drahtlose Telephonie*, Berlin, 1907. There is no doubt that the transmission of articulate sounds and speech over long distances without wires by means of electric waves is not only possible as an experimental feat but may perhaps come to be commercially employed. In connexion with this part of the subject a brief reference should also be made to M. Wien's method of impact excitation by employing a form of spark gap which quenches the primary discharge instantly and excites the free oscillations in the antenna by impact or shock.

Instruments and Appliances for making Measurements in Connexion with Wireless Telegraphy.—The scientific study of electric wave telegraphy has necessitated the introduction of many new processes and methods of electrical measurement. One important measurement is that of the wave-length emitted from an antenna. In all cases of wave motion the wave-length is connected with the velocity of propagation of the radiation by the relation $v=n\lambda$, where n is the frequency of the oscillations and λ is the wave-length. The velocity of propagation of electric waves is the same as that of light, viz., about 1000 million feet, or 300 million metres, per second. If therefore we can measure the frequency of the oscillations in an antenna we are able to tell the wave-length emitted. Instruments for doing this are called wave meters and are of two kinds, open circuit and closed circuit. Forms of open circuit wave meter have been devised by Slaby and by Fleming. Slaby's wave meter consists of a helix of non-insulated wire wound on a glass tube. This helix is presented or held near to the antenna, and the length of it shortened until oscillations of the greatest intensity are produced in the helix as indicated by the use of an indicator of fluorescent paper.

Closed circuit wave meters have been also devised by J. Dönitz[1] and by Fleming.[2] In Dönitz's wave meter a condenser of variable capacity is associated with inductance coils of various sizes, and the wave meter is placed near the antenna so that its inductance coils have induced currents created in them. The capacity of the condenser is then altered until the maximum current, as indicated by a hot wire ammeter, is produced in the circuit. From the known value of the capacity in that position and the inductance the frequency can be calculated. The Fleming closed circuit wave meter, called by him a cymometer, consists of a sliding tube condenser and a long helix of wire forming an inductance; these are connected together and to a copper bar in such a manner that by one movement of a handle the capacity of the tubular condenser is altered in the same proportion as the amount of the spiral inductance which is included in the circuit. If, then, a long copper bar which forms part of this circuit is placed in proximity to the transmitting antenna and the handle moved, some position can be found in which the natural time period of the cymometer circuit is made equal to the actual time period of the telegraphic antenna. When this is the case the amplitude of the potential difference of the surfaces of the tubular condenser becomes a maximum, and this is indicated by connecting a vacuum tube filled with neon to the surfaces of the condenser. The neon tube glows with a bright orange light when the adjustments of the cymometer circuit are such that it is in resonance with the wireless telegraph antenna. The scale on the cymometer then shows directly the wave-length and frequency of the oscillations.[3]

An immense mass of information has been gathered on the scientific processes which are involved in electric wave telegraphy. Even on fundamental questions such as the function of the earth interconnexion with it physicists differ in opinion to a considerable extent. Starting from an observation of Marconi's, a number of interesting facts have been accumulated on the absorbing effect of sunlight on the propagation of long Hertzian waves through space, and on the disturbing effects of atmospheric electricity as well as upon the influence of earth curvature and obstacles of various kinds interposed in the line between the sending and transmitting stations.[4]

Electric wave telegraphy has revolutionized our means of communication from place to place on the surface of the earth, making it possible to communicate instantly, and certainly between places separated by several thousand miles, whilst at the same time it has taken a position of the greatest importance in connexion with naval strategy and communication between ships and ships and the shore in time of peace. It is now generally recognized that Hertzian wave telegraphy, or radio-telegraphy, as it is sometimes called, has a special field of operations of its own, and that the anticipations which were at one time excited by uninformed persons that it would speedily annihilate all telegraphy conducted with wires have been dispersed by experience. Nevertheless, transoceanic wireless telegraphy over long distances, such as those across the Atlantic and Pacific oceans, is a matter to be reckoned with in the future, but it remains to be seen whether the present means are sufficient to render possible communication to the antipodes. The fact that it has become necessary to introduce regulations for its control by national legislation and international conferences shows the supremely important position which it has taken in the short interval of one decade as a means of communicating human intelligence from place to place over the surface of the globe. An important International Conference on radio-telegraphy was held in Berlin in 1906, and as a result of its deliberations international regulations have been adopted by the chief Powers of the world. The decisions of the Conference were ratified for Great Britain by the British government on July 1, 1908.

TELEMACHUS, in Greek legend (*Odyssey* i.–iv., xv.–xxiv.; Hyginus, *Fab.* 127), son of Odysseus and Penelope. When he reached manhood, he visited Pylos and Sparta to make inquiries about his father, who had been absent for nearly twenty years. On his return, he found that Odysseus had reached home before him. Then father and son, aided by Eumaeus and Philoetius, slew or drove out the suitors of Penelope (see ODYSSEUS). According to later tradition, Telemachus became the husband of Circe and by her the father of Latinus and of a daughter Roma, afterwards the wife of Aeneas. In another story, he married a daughter of Circe, named Cassiphone; having slain his mother-in-law in a quarrel, he was himself killed by his wife. This is the only notice of the death of Telemachus. The foundation of Clusium in Etruria was attributed to him.

TELEMARK, or THELEMARK, a district of southern Norway, wholly comprised in the *amt* (county) of Bratsberg. It covers the uplands and fjelds of the southward projection of the country, having its highest point in the Gaustafjeld (6200 ft.); and contains several large and beautiful lakes, as Nordsjö, Bandaksvand, Tinsjö, Mjösvand and Totakvand. The two first are connected by the Bandaks canal, a fine engineering work giving access from the port of Skien to Dalen at the head of Bandaksvand. From Dalen, which may be reached by road from the railway at Kongsberg (38 miles) a driving road much frequented by travellers runs north-west. It traverses a precipitous wooded gorge, its course in parts hewn out of the rock, and skirts the Börte and Grungedal lakes, follows the Flaathyl river, passes the Vafos and Little Rjukanfos (waterfalls), and Lake Voxli, and culminates at Haukelidsaeter, a station grandly situated among the fjelds at a height of 3085 ft. It rises to the watershed (3715 ft.) and then, leaving the district, descends abruptly with a remarkable winding course to Röldal (58 miles from Dalen), and soon divides, one branch surmounting the Horrebraekke pass and continuing to Odde, the other traversing the beautiful Bratlandsdal. On the Kongsberg-Dalen road is Hitterdal, with a good specimen of the Stavekirke or medieval timber-built church. A divergence from this route may be made by way of Tinsjö to Fosso, where the Maan river forms a fine fall (Rjukanfos) of 415 ft.

TELEOLOGY (Gr. τέλος, end), in philosophy and theology, strictly that branch of study which considers "final causes" as real principles of explanation, *i.e.* which explains things as existing solely as pre-requisites of the results which they produce. More commonly the term is applied to the doctrine that the universe as a whole has been planned on a definite design, or at least that it tends towards some end. The term has been used very loosely, and its meaning has changed considerably. The root idea arises from the analogy of the acts of human beings which are observed to have certain purposes: hence it was natural to assume that the whole sum of existence with its amazing complexity and its orderly progress can be explained only on the assumption of a similar plan devised by a conscious agent. Such a view is essential to any theistic view of the universe which postulates God as the Creator, omniscient and all-good. The modern theory of evolution, on the other hand, has reintroduced a scientific teleology of another type. This is discussed, from the biologist's point of view, in the article ZOOLOGY. Teleology, in this narrower sense, as the study of the adaptation of organic structures to the service of the organisms in which they occur, was completely revolutionized by Darwinism and the research founded on it.

TELEOSTOMES, members of the third sub-class of the class Fishes, being all the fishes in which the skull is invested with membrane bones, viz., the Crossopterygians, the Dipnoans, the Ganoids and the Teleosteans. They may be further defined as fishes with an ossified or cartilaginous skeleton, a lower jaw, gills inserted on the gill-arches, a single gill-opening on each side (exceptionally fused with its fellow on the ventral side), an opercle formed of one or several bones, the body usually covered with scales or bony plates, an air-bladder or lung, at least in the primitive forms, and without copulatory paired organs or "claspers."

The term which designates this sub-class has been adopted by Sir R. Owen, E. D. Cope, and A. S. Woodward in a less comprehensive sense, the Dipneusti being regarded by them as constituting a separate sub-class, and its inventor, C. L. Bonaparte (1838) had proposed it in a more restricted sense, the sturgeons, lophobranchs and plectognaths being excluded. T. Gill (1872) was the first to use it in the acceptation taken in the present article. Whether the Ostracophores should be included among the Teleostomes, as recently proposed by C. T. Regan, is still open to doubt. The sub-class is here divided into four orders, but it is difficult to decide whether, in an ascending series, the Crossopterygians or the Ganoids should be placed first. From the point of view of the evolution of the paired fins, accepting the lateral fin-fold theory as the better supported by the evidence at hand, there is much to say in favour of regarding the Chondrostean Ganoids as the more primitive type. From another point of view the condition of the air-bladder in the existing Crossopterygians appears to represent the earliest form assumed by this important organ, which it seems rational to conclude was originally evolved as an accessory breathing organ and later became transformed into a hydrostatic apparatus (Ganoids and Teleosteans) on the one hand, into a true lung (Dipnoans and Batrachians) on the other. Guided by the second consideration, assuming that the air-bladder of the fossil Crossopterygians conformed to the type known in their recent representatives, and also in deference to palaeontological chronology, whatever it be worth in the present state of our knowledge, we shall begin the series with the Crossopterygians, which pass into the Dipnoans, and then take up the Ganoids, which lead up very gradually to the Teleosteans, the dominant group at the present day. But we do not deny the force of the arguments adduced by Regan in attempting to show that the paired fins of the Chondrostean Ganoids are a nearer approach to the primitive condition than are those of the Crossopterygians. No doubt some day we shall become acquainted with still older Teleostomes, which we may expect to establish the connexion between the two types which in Palaeozoic times have evolved on parallel lines.

ORDER I.—CROSSOPTERYGII

Paired fins, at least the pectorals, lobate, having an endo-skeletal axis more or less fringed with dermal rays. Mandibular arch suspended from the upper segment of the hyoid arch (hyostylic skull). Splenial bone present. No supraoccipital bone. A pair of large jugular plates, sometimes with small lateral plates and an anterior azygous element, developed in the branchiostegal membrane between the mandibular rami. Heart with a contractile, multivalvular conus arteriosus; intestine with a spiral valve; air-bladder with pneumatic duct communicating with the ventral side of the oesophagus.

Maxillary bone large, toothed, bordering the mouth. Bones of the upper surface of the skull mostly paired. Pectoral arch with both clavicle (so-called infra-clavicle) and cleithrum. Ventral fins inserted far back. With few exceptions (tail of Coelacanthidae, dorsal and caudal fins of Polypteridae) the dermal rays of the unpaired fins more numerous than their endo-skeletal supports, a primitive character also found in the lower Ganoids, but disappearing in the higher.

SUB-ORDER I.—OSTEOLEPIDA

(Including the Haplistia, Rhipidistia and Actinistia.) Pectoral fins obtusely or acutely lobate, articulating with the pectoral girdle by a single basal endo-skeletal element. Nostrils on the lower side of the snout. Two dorsal fins.

Families: Osteolepidae, Rhizodontidae, Holoptychidae, Coelacanthidae.

The scales may be rhombic and thickly coated with ganoine (Osteolepidae) or cycloid. The vertebral axis is strongly heterocercal in the Osteolepidae and Holoptychidae, and diphycercal or intermediate between the heterocercal and the diphycercal types in the other families; usually acentrous, sometimes with ring-like calcifications (some of the Rhizodontidae). In the Holoptychidae the pectoral fin is extremely similar to that of the Dipneusti of the family Dipteridae, which they resemble closely in form and scaling. Their teeth are remarkable for their complicated structure, resembling that of the Labyrinthodont Batrachians. A pineal foramen is present between the frontal bones in most of the Rhizodontidae.

The Osteolepidae were mostly moderate-sized fishes, the largest (*Megalichthys*) measuring about 4 ft. in length.

These Crossopterygians first appear in the Lower Devonian, are abundant in the Upper Devonian, Carboniferous and Permian; in later periods they are represented only by the more specialized Coelacanthidae, which appear in the Lower Carboniferous, and persist as late as the Upper Chalk.

SUB-ORDER II.—CLADISTIA

Pectoral fin obtusely lobate, with three basal endo-skeletal elements. Nostrils on the upper side of the snout. A single dorsal fin, formed of a series of detached rays.

A single family: Polypteridae.

The existing Crossopterygians which form this sub-order differ very considerably from the extinct Osteolepida, perhaps quite as much as these differ from the Dipneusti. The ventral fins are not lobate, the vertebral column is well ossified and its termination is of the diphycercal type. Spiracles, covered by bony valves, are present on the upper surface of the head. The dorsal fin is unique among fishes, being formed of detached rays consisting of a spine-like fulcral scale supporting the fringes of the ray; these rays have been regarded, erroneously, as representing so many distinct fins, or "finlets." The scales are bony, rhombic and thickly coated with ganoine.

The Polypteridae are confined to tropical Africa and the Nile, and represented by two genera: *Polypterus* and *Calamichthys*, the former moderately elongate and provided with ventral fins, the latter serpentiform and devoid of ventrals. We now know ten species of *Polypterus*, from the Nile, the Congo, the rivers of West Africa, and lakes Chad, Rudolf and Tanganyika, and one of *Calamichthys*, which inhabits West Africa from the Niger delta to the Chiloango. The largest species of *Polypterus* reach a length of nearly 4 ft. The young are provided with an external opercular gill very similar to the gills of larval salamanders. The air-bladder acts as an accessory breathing organ, although these fishes are not known ever to leave the water. The development is stated by the late J. S. Budgett to be even more Batrachian-like than that of the Dipneusti, but the results of the study of the material collected by him shortly before his death have not yet been published.

Order II.—DIPNEUSTI

Often called Dipnoi, a term proposed for this order by J. Müller in 1845, but which had already been used for the Batrachians (F. Leuckart, 1821) before the discovery of *Lepidosiren*. The substitute Dipneusti (E. Haeckel, 1866) is, therefore, preferable.

Paired fins lobate, or reduced to a jointed endo-skeletal axis. Upper segment of the mandibular arch confluent with the skull (autostylic skull). Praemaxillary and maxillary bones absent, dentary absent or small and toothless; teeth on the palato-pterygoid and splenial bones, sometimes also on the vomers. No supraoccipital bone. Heart trilocular, with a contractile, multivalvular conus arteriosus; intestine with a spiral valve; air-bladder transformed into a single or double lung, opening at the glottis on the ventral side of the pharynx.

The cranial roof-bones include median as well as paired plates, which cannot easily be homologized with those of other Teleostomes; in the older forms, these bones are small and numerous, and, coated with ganoine, appear on the surface of the head, whilst in the later forms they are reduced in number as well as in the degree of ossification, and have sunk below the skin. Pectoral arch with both clavicle and cleithrum. Ventral fins inserted far back. Vertebrae acentrous. Dermal rays of vertical fins much more numerous than their supports, which correspond in number to the neural and haemal arches. Nostrils on the lower side of the snout, the posterior within the mouth. Scales cycloid (almost quadrate in *Sagenodus*, a genus of Ctenodontidae).

Families: Dipteridae, Ctenodontidae, Uronemidae, Ceratodontidae, Lepidosirenidae.

The Dipteridae are heterocercal and have two dorsal fins, as in the Crossopterygian Holoptychidae; in the other families the dorsal fin is elongate and single, and extends to the extremity of the tail, which belongs to the diphycercal type. In the three first families, which are entirely Palaeozoic, ranging from the Devonian to the Permian, the dental plates nearly always exhibit more or less clearly the points of the separate denticles of which, as shown by the development of *Neoceratodus*, they were originally composed, but vomerine teeth, such as exist in the Ceratodontidae and Lepidosirenidae, do not appear to have existed. In the Dipteridae alone the scales were covered with dense, punctate ganoine, which has become much reduced or disappeared entirely in the other members of this order. The two first families had well-developed gular plates.

In the Ceratodontidae, which first appeared in the Trias and have persisted to the present day, the skull is more feebly ossified than in the earlier forms, and this may well be looked upon as a degeneration, since the head of the Triassic *Ceratodus sturi*, whilst exhibiting the same arrangement of bones as in the living form, differs in its higher degree of ossification; and as the dermal rays of the caudal fin also exhibit distinctive features in a fossil of the same period, it is advisable to refer the existing *Ceratodus forsteri* to a distinct genus, which has been named *Neoceratodus* by Castelnau (1876) and *Epiceratodus* by Teller (1891). But there can be no question that *Neoceratodus* is very closely related to *Ceratodus*. Its only known species, *N. forsteri*, variously known as the barramunda, flat-head, and Dawson or Burnett salmon, inhabits the Burnett, Dawson and Mary rivers in Queensland, and was first discovered in 1870. Its anatomy was made known by the memoir of A. Günther, and numerous contributions by T. H. Huxley, E. R. Lankester, J. E. V. Boas, W. B. Spencer and others, whilst its development has been elaborately worked out by R. Semon. This fish, which grows to a length of 6 ft., has the body moderately elongate and compressed, covered with large thin scales, and the paired fins are acutely lobate, consisting of a median jointed axis fringed on each side by a series of radialia supporting fine dermal rays (archipterygium of C. Gegenbaur). Although provided with a lung, which is single, *Neoceratodus* never leaves the water. It feeds on both animal and vegetable matter, the specimens kept in the London Zoological Gardens readily eating lettuce in addition to frogs and bits of raw meat. The early development resembles very closely that of Batrachians, but there are no metamorphoses properly speaking, and at no period does the young possess external gills or a holder or cement organ.

The South American *Lepidosiren* and the tropical African *Protopterus*, which constitute together the family Lepidosirenidae, were discovered long before *Neoceratodus*, the former in 1836, the latter in 1839. These fishes are much more specialized than are the Ceratodontidae; the body is more or less eel-shaped, the scales are thinner, the paired fins are reduced to slender styliform appendages formed of a jointed axis with or without a unilateral fringe of cartilaginous rays bearing fine dermal rays, and the lung is paired. The development is even more Batrachian-like than that of *Neoceratodus*, and the larvae are provided with a cement organ and four (*Lepidosiren*) or five (*Protopterus*) fringed external gills, traces of which may persist throughout life in *Protopterus*. The habits and development of *Lepidosiren* have been investigated by J. Graham Kerr, and those of *Protopterus* by J. S. Budgett. In both the eggs are deposited in nests in the water and the male keeps guard over the eggs and young. The food is both animal and vegetable, as in *Neoceratodus*. During the dry season, *Protopterus* burrows in the mud of drying marshes and, surrounded by a cocoon formed of hardened mucus secreted by glands of the skin, it spends weeks or months in a dormant condition, breathing exclusively by its lungs; dry clay balls containing such cocoons have often been brought over to Europe, and when soaked in water, the *Protopterus* is released in a most lively condition. Three species of *Protopterus* are known from different parts of Africa, the type species being *P. annectens*, an inhabitant of West Africa, from the Senegal to the Niger, and Lake Chad. Of *Lepidosiren* only one species is known, *L. paradoxa*, living in the Amazon and Paraguay basins.

Great uncertainty, and much difference of opinion among palaeichthyologists, still prevail as to the position in the system of a group of Devonian fishes, of which *Coccosteus* and *Dinichthys* are the best-known representatives. Long placed with the Ostracophores is a group instituted by Sir F. McCoy in 1848 under the name of Placodermi; they were removed from their vicinity by A. S. Woodward in 1889, and referred to the Dipnoans as an order which he proposed to call Arthrodira. This view was based mainly on the assumption that the skull was autostylic and that maxillary bones were not developed, and also on the resemblance, previously noticed by J. S. Newberry, between the dentition of *Dinichthys* and that of *Protopterus*. Woodward's proposal has not met with general acceptance, but it is strongly supported by the recent investigations of C. R. Eastman, who has added fresh arguments in favour of the autostylic condition of the skull and the homology of the cranial roof-plates with those of the Dipnoans, the Ceratodontidae in particular. On the other side, B. Dean and L. Hussakof deny such homologies, and even regard the dental mechanism of the Arthrodira as something quite different from the jaws and teeth of other vertebrates, and revert to the view of McCoy in placing the Arthrodira in a group Placodermata, which they regard as a class co-ordinate in rank with such divisions as Cyclostomi and Pisces.

In the present state of our knowledge it is perhaps best to leave the Arthrodira with or near the Dipneusti. They are thus defined by Woodward:—Fishes with both head and trunk armoured, in the more specialized genera the shield of the abdominal region articulating with the head-shield in ginglymoid facettes (Gr. γιγγλυμος, a hinge) which admit of free motion (hence the name *Arthrodira*, joint-neck). No trace of a hyomandibular bone. Jaws paralleled by those of the existing Dipneusti. Notochord persistent. Pectoral fins unknown; ventral fins rudimentary.

Two families: Coccosteidae and Dinichthyidae, from the Devonian of Europe and North America.

Some of the species of *Dinichythys* reached a great size, the head sometimes measuring a metre across.

Order III.—GANOIDEI

Paired fins not lobate. Mandibular arch suspended from the upper segment of the hyoid arch (hyostylic skull). Splenial bone present. No supraoccipital bone. Unpaired fins often with fulcra. Heart with a contractile, multivalvular conus arteriosus; intestine with a spiral valve; air-bladder with pneumatic duct communicating with the dorsal side of the oesophagus.

Sub-order I.—CHONDROSTEI

Pectoral arch with both clavicle and cleithrum. Ventral fins inserted far back, with well-developed endo-skeletal rays (baseosts); dermal rays of the dorsal and anal fins more numerous than their endo-skeletal supports. Heterocercal. Vertebrae acentrous.

Families: Palaeoniscidae, Platysomidae, Catopteridae, Belonorhynchidae, Chondrosteidae, Polyodontidae, Acipenseridae.

In the three first families (Devonian to Jura), the mouth is toothed, praemaxillary bones are present, and the maxillaries are large, the bones of the upper surface of the head are paired, branchiostegal rays are present, and the body is covered with rhomboidal, typically ganoid bony scales. In the fourth family (Trias to Lias), the snout is much elongate, and longitudinal series of scutes extend along the body, one on the back, one on the belly, and one on each side. The Liassic Chondrosteidae show an approach to the sturgeons, and form a sort of connecting link between them and the Palaeoniscidae. The mouth was edentulous, praemaxillary bones were absent, but the maxillary bone was well developed, though small; the membrane bones of the skull were paired;

branchiostegal rays were present; scales were absent, except on the caudal lobe.

In the modern Polyodontidae and Acipenseridae, whose first representatives appear in the Eocene, praemaxillaries are absent and the mouth is edentulous (Acipenseridae) or beset with minute teeth (Polyodontidae), the membrane bones of the skull are more irregular and comprise azygous elements, branchiostegal rays are absent, and the body is naked or covered with small ossifications and longitudinal series of bony scutes, whilst the caudal fin is scaled exactly as in the Palaeoniscidae. Barbels are absent in the Polyodontidae.

In the Polyodontidae, represented by one species, the paddle-fish or spoon-bill (*Polyodon folium*), in the Mississippi, Ohio and Missouri rivers of North America, and by another (*Psephurus gladius*) in the Yang-tse-kiang and Hoang Ho rivers of China, the snout is produced into a very long, spatulate (*Polydon*) or sub-conical (*Psephurus*) appendage, apparently useful in stirring up the mud of the thick waters in which these fishes live, and perhaps a tactile organ compensating the very reduced size of the eyes. *Psephurus gladius* is said to grow to a length of 20 ft. The sturgeons (Acipenseridae) are divided into two genera: *Acipenser*, distributed over the coasts and fresh waters of the temperate parts of the northern hemisphere, and *Scaphirhynchus*, inhabiting North America and Central Asia. About twenty species of *Acipenser* and five of *Scaphirhynchus* are known. The sturgeons are of great value for their flesh, their eggs (caviare) and the isinglass from the air-bladder; several species are migratory, ascending rivers to spawn. The largest species attain a length of 10 to 18 ft.

Sub-order II.—HOLOSTEI

Clavicle proper absent. Ventral fins inserted more or less far back, without or with mere rudiments of endo-skeletal rays; dermal rays of the dorsal and anal fins corresponding to their endo-skeletal supports. Caudal fin of an abbreviate-heterocercal or homocercal type.

Families: Semionotidae, Macrosemiidae, Pycnodontidae, Eugnathidae, Pachycormidae, Lepidosteidae, Aspidorhynchidae, Amiidae.

First appear in the Permian with the Semionotidae, become abundant in the Trias, dominant in the Jurassic, begin to decline in the Cretaceous, and from the Eocene to the present day are reduced to the two families Lepidosteidae and Amiidae, the modern representatives of which inhabit the fresh waters of North America.

In most of the Holostei the scales are bony, rhombic and covered with an enamel-like (ganoine) coating, but there is every gradation between this so-called ganoid type of scaling and the cycloid type exemplified by the Amiidae. Fulcra also disappear in some of the more specialized types. The mouth is always large and toothed, and branchiostegal rays are invariably present; a single gular plate is often present. In the earlier groups the notochord was persistent, with or without annular centra, or with each centrum composed of two elements—pleurocentrum and hypocentrum; these elements remain distinct and alternate in the caudal region of the Amiidae, whilst in the Lepidosteidae the centra are as fully developed as in most Teleosteans, and opisthocoelous or convexo-concave.

The pike-like genus *Lepidosteus* was abundant in Europe in Eocene and Miocene times, and is now represented by three species in eastern North America, Mexico and Cuba. The largest species reaches a length of 10 ft. *Amia*, the bowfin, of similar geological age, is a much smaller fish, not exceeding 2 ft., from the eastern parts of North America. Its air-bladder is cellular and acts as an accessory breathing organ. It deposits its eggs in a sort of nest, which is protected by the male, who for some time accompanies the swarm of young fry and defends them with great courage.

Leedsia problematica, one of the Pachycormidae from the Oxford clay, probably reached a length of 30 ft., and is the largest known Teleostome.

Order IV.—TELEOSTEI

Paired fins non-lobate, the ventrals without baseosts. Mandible suspended from the upper segment of the hyoid arch. Splenial bone absent. Supraoccipital bone present. Heart without muscular conus arteriosus, or with much reduced conus, with one, exceptionally two, rows of valves. Air-bladder, if present, communicating with the dorsal side of the oesophagus or digestive tract, or completely closed.

Sub-order I.—MALACOPTERYGII

Air bladder, if present, with a duct. Opercle well developed. Pectoral arch suspended from the skull; mesocoracoid bone present. Fine without spines, the ventrals abdominal (rarely absent). Anterior vertebrae distinct, without Weberian ossicles.

Families: Pholidophoridae, Archaeomenidae, Oligopleuridae, Leptolepidae, Elopidae, Albulidae, Mormyridae, Hyodontidae, Notopteridae, Osteoglossidae, Pantodontidae, Ctenothrissidae, Phractolaemidae, Saurodontidae, Chirocentridae, Clupeidae, Chanidae, Salmonidae, Alepocephalidae, Stomiatidae, Gonorhynchidae, Cromeriidae.

Unquestionably the most generalized sub-order, having most in common with the Holostean ganoids. The first four families, of Triassic to Cretaceous age, are so closely connected with these Ganoids that their allocation to the Teleosteans must be regarded as provisional. Some of the Pholidophoridae were flying fishes. The Elopidae and Albulidae are also low forms, traced back to the Cretaceous seas, having points in common with the Ganoids (gular plate in the former, conus arteriosus with two rows of valves in the latter). The Mormyridae are among the most extraordinary fishes, and, like the four families which follow in the above list, confined to fresh waters. Other families, like the Chirocentridae, Clupeidae and Salmonidae, are entirely or partly marine, the two last being of great economic importance. The Alepocephalidae and Stomiatidae are restricted to the deep sea.

See Anchovy, Herring, Menhaden, Mormyr, Pilchard, Salmonidae, Shad and Sprat.

Sub-order II.—OSTARIOPHYSI

Air-bladder, if well developed, with a duct. Pectoral arch suspended from the skull; mesocoracoid bone present. Fins without spines, or dorsal and pectoral with a single spine formed by the co-ossification of the segments of an articulated ray. The anterior four vertebrae strongly modified, often co-ossified, and bearing a chain of small bones (so-called Weberian ossicles) connecting the air-bladder with the ear.

Families: Characinidae, Gymnotidae, Cyprinidae, Siluridae, Loricariidae, Aspredinidae.

One of the most natural groups of the class Pisces, as demonstrated by M. Sagemehl in 1885. The Characinidae are the most generalized, although perhaps not directly derived from the Amiid Ganoids, as believed by Sagemehl; they show great variety of form and dentition, and are confined to Central and South America and Africa. The Gymnotidae, which include the so-called electric eel, are closely related to the Characinidae, and occur only in South America. The largest families are the Cyprinidae and Siluridae. With the exception of a few Siluridae, the Ostariophysi are all fresh-water fishes.

Sub-order III.—SYMBRANCHII

Eel-shaped fishes without paired fins, with the pectoral arch free or suspended from the skull, without mesocoracoid bone, and with the anterior vertebrae distinct, without Weberian ossicles. Gill-openings confluent into a single, ventral slit. Air-bladder absent.

Families: Symbranchidae and Amphipnoidae.

Like the Apodes, which they resemble in general appearance, these fishes are no doubt derived from some low type with abdominal ventral fins, but whether from the Malacopterygii or the Haplomi we have as yet no data from which to conclude. Inhabitants of the fresh or brackish waters of south-eastern Asia, tropical America, Australia and Tasmania.

In the cuchia, *Amphipnous cuchia*, the gills are much reduced, and a respiratory air-sac extends on each side of the body behind the head, communicating with the gill-cavity.

Sub-order IV.—APODES

Air-bladder, if present, with a duct. Praemaxillary bones absent; the maxillaries, if present, separated on the median line in front by the coalescent ethmoid and vomer. Pectoral arch, if present, not connected with and remote from the skull; mesocoracoid bone absent. Fins without spines, the ventrals absent. Anterior vertebrae distinct, without Weberian ossicles.

Elongate, serpentiform fishes with naked skin, or with minute scales imbedded in the skin.

Families: Anguillidae, Nemichthyidae, Synaphobranchidae, Saccopharyngidae, Muraenidae.

A large group of aberrant, degraded fishes, heralded by the Cretaceous genus *Urenchelys*, the most generalized of eels. Mostly marine, many bathybial; some living principally in fresh water, but breeding in the sea, like the common eel (see articles Eel and Muraena).

Sub-order V.—HAPLOMI

Air-bladder, if present, with a duct. Opercle well developed. Pectoral arch suspended from the skull; no mesocoracoid bone. Fins usually without, rarely with a few spines; ventrals abdominal, if present. Anterior vertebrae distinct, without Weberian ossicles.

Families: Galaxiidae, Haplochitonidae, Enchodontidae, Esocidae, Dalliidae, Scopelidae, Alepidosauridae, Cetomimidae, Chirothricidae, Kneriidae, Cyprinodontidae, Amblyopsidae, Stephanoberycidae, Percopsidae.

The absence of the mesocoracoid bone distinguishes these fishes from the Malacopterygii, and the presence of a duct to the air-bladder separates them from the Percesoces, to some of which, the Scombresocidae and the Atherinidae, they are linked by the Cyprinodontidae; whilst the Scopelidae are connected with the Berycidae by the Stephanoberycidae.

The type family of this sub-order is that of the Esocidae or pike, inhabitants of the fresh waters of Europe, northern Asia, and North

America. The Galaxiidae are mostly fresh-water fishes and have a wide distribution in the southern hemisphere (southern parts of South America, New Zealand, South Australia and Tasmania, Cape of Good Hope), one species being identical in South America, the Falkland Islands, New Zealand and Tasmania. Their distribution has been regarded as affording support to the theory of an Antarctic continent in Tertiary times. However, several of the species spend part of their life, and even breed, in the sea, whilst others may be regarded as having become more recently adapted to fresh water, so that the argument derived from their range is not so strong as if we had to deal with exclusively fresh-water fishes. The Cyprinodontidae are partly brackish, partly fresh-water fishes, whilst the Scopelidae, which are traced back to the Chalk, are all marine, many being inhabitants of great depths.

Sub-order VI.—HETEROMI

Air-bladder without duct. Opercle well developed, parietal bones separating the frontals from the supraoccipital. Pectoral arch suspended from the supraoccipital or the epiotic, the post-temporal small and simple or replaced by a ligament; no mesocoracoid bone. Ventral fins abdominal, if present.

Families: Dercetidae, Halosauridae, Lipogenyidae, Notacanthidae, Fierasferidae.

Closely related to the Haplomi, but separated chiefly on account of the closed air-bladder. Mostly deep-sea fishes, some of which appeared as early as the Cretaceous period. The genus *Fierasfer* comprises small degraded fishes commensals of Holothurians and bivalve molluscs.

Sub-order VII.—SELENICHTHYES

Air-bladder without duct. Opercle well developed. Pectoral arch suspended from the skull; no mesocoracoid bone. Fins without spines. Ventral fins abdominal, with very numerous (15 to 17) rays.

A very aberrant type, of uncertain affinities. Its only representative is the opah, *Lampris luna*, a large pelagic fish of wide distribution.

Sub-order VIII.—THORACOSTEI

Embracing the Hemibranchii and Lophobranchii, but excluding the Hypostomides (Pegasidae), which the investigations of F. E. Jungersen show to be aberrant mail-cheeked Acanthopterygians.

Air-bladder without duct. Pectoral arch suspended from the skull; no mesocoracoid bone. Ventral fins abdominal, if present. Branchial arches more or less reduced.

Families: Gastrosteidae, Aulorhynchidae, Protosyngnathidae, Aulostomatidae, Fistulariidae, Centriscidae, Amphisilidae, Solenostomidae, Syngnathidae. The two latter families institute the division Lophobranchii, in which the gill-lamellae are enlarged and form rounded lobes.

See articles SEA-HORSE, STICKLEBACK, and PIPE-FISHES.

Sub-order IX.—PERCESOCES

Air-bladder, if present, without duct. Parietal bones separated by the supraoccipital. Pectoral arch suspended from the skull; no mesocoracoid bone. Ventral fins, if present, abdominal, or at least with the pelvic bones not solidly attached to the clavicular arch.

Families: Scombresocidae, Ammodytidae, Atherinidae, Mugilidae, Polynemidae, Chiasmodontidae, Sphyraenidae, Tetragonuridae, Stromateidae, Icosteidae, Ophiocephalidae, Anabantidae.

This series of families connects the Haplomi with the Acanthopterygii. The Percesoces are mostly marine, but the two last families are exclusively fresh-water. Some are inhabitants of great depths, others are pelagic, like the flying-fish (*Exocoetus*).

Sub-order X.—ANACANTHINI

Air-bladder without duct. Parietal bones separated by the supraoccipital; prootic and exoccipital separated by the enlarged opisthotic. Pectoral arch suspended from the skull; no mesocoracoid bone. Ventral fins below or in front of the pectorals, the pelvic bones posterior to the clavicular symphysis and only loosely attached to it by ligament. Fins without spines.

Families: Macruridae, Gadidae, Muraenolepididae.

Nearly all marine. The Macruridae are among the most characteristic fishes of the great depths. The Gadidae include some of the most valuable food-fishes.

Sub-order XI.—ACANTHOPTERYGII

Air-bladder usually without duct. Opercle well developed; supraoccipital in contact with the frontals. Pectoral arch suspended from the skull; no mesocoracoid bone. Ventral fins thoracic or jugular, more or less firmly attached to the clavicular arch. Gill-opening usually large, in front of the base of the pectoral fin.

The character from which this sub-order, the most comprehensive of the whole class, derives its name, viz., the presence of non-articulated, spiny rays in the dorsal and anal fins, is by no means universal, exceptions to the rule being numerous.

Division I. Beryciformes.—Families: Berycidae, Monocentridae, Polymixiidae.

The most primitive of the Acanthopterygians, already well represented in the Chalk. A duct has been observed to be sometimes present between the air-bladder and the digestive tract. All marine, several bathybial.

Division II. Perciformes.—Families: Pempheridae, Serranidae, Anomalopidae, Pseudochromididae, Cepolidae, Hoplognathidae, Sillaginidae, Sciaenidae, Scorpididae, Caproidae, Centrarchidae, Cyphosidae, Lobotidae, Toxotidae, Nandidae, Percidae, Acropomatidae, Gerridae, Lactariidae, Trichodontidae, Pristipomatidae, Sparidae, Mullidae, Latrididae, Haplodactylidae, Chaetodontidae, Drepanidae, Osphromenidae, Acanthuridae, Teuthididae, Embiotocidae, Cichlidae, Pomacentridae, Labridae, Scaridae.

The Percidae, Centrarchidae, Toxotidae, Nandidae, Osphromenidae, Embiotocidae, and Cichlidae are fresh-water fishes, the others are all or nearly all marine. *Aipichthys*, which is included among the Scorpididae, is one of the few Acanthopterygian types known to have existed as early as the Cretaceous period.

See articles CICHLIDS, MULLET, MURRAY COD, PARROT-FISHES, PERCH, PIKE-PERCH, SHEEPSHEAD, WRASSE.

Division III. Scombriformes.—Families: Carangidae, Rhachicentridae, Scombridae, Trichiuridae, Histiophoridae, Xiphiidae, Luvaridae, Coryphaenidae, Bramidae.

Marine fishes, several being pelagic and among the largest Teleosteans and swiftest swimmers. See articles HAIR-TAIL, MACKEREL, PILOT-FISH, SWORD-FISH, TUNNY.

Division IV. Zeorhombi.—Families: Zeidae, Amphistiidae, Pleuronectidae.

Division V. Kurtiformes.—A single family, Kurtidae, with a single genus and species from the Indian and Pacific oceans.

Division VI. Gobiiformes.— A single family, Gobiidae.

Division VII. Discocephali.— A single family, Echeneididae.

The remarkable remoras attach themselves by means of a cephalic disk to boats or to sharks, turtles, cetaceans, and other large swift-swimming animals. They form an isolated group, and have no real affinity with the Scombridae, with which they have long been associated.

Division VIII. Scleroparei.—Families: Scorpaenidae, Hexagrammidae, Comephoridae, Rhamphocottidae, Cottidae, Cyclopteridae, Platycephalidae, Hoplichthyidae, Agonidae, Pegasidae, Triglidae, Dactylopteridae.

The "Mail-cheeked" Acanthopterygians include a great variety of forms, mostly living in the sea, the best known being referred to in the articles FLYING-FISH, GURNARD, LUMP-SUCKER, and MILLER'S-THUMB.

Division IX. Jugulares.—Families: Trachinidae, Percophiidae, Leptoscopidae, Nototheniidae, Uranoscopidae, Trichodontidae, Callionymidae, Gobiesocidae, Blenniidae, Batrachidae, Pholididae, Zoarcidae, Congrogadidae, Ophidiidae, Podatelidae.

Nearly all marine, some deep-sea. *Macrius amissus*, which probably belongs to the Leptoscopidae, measures 5 ft. and is the largest known deep-sea Teleostean. The other members of this division are mostly small, *Anarrhichas* being another exception. The weevers (*Trachinus*) are dangerous stinging fishes.

Division X. Taeniosomi.—Families: Trachypteridae, Lophotidae.

Deep-sea or pelagic fishes, some attaining a large size.

Sub-order XII.—OPISTHOMI

Air-bladder without duct. Opercle well developed, hidden under the skin; supraoccipital in contact with the frontals. Pectoral arch suspended from the vertebral column, far behind the skull; no mesocoracoid bone. Vertical fins with spines. Ventral fins absent.

Eel-shaped fishes standing in the same relation to the Acanthopterygii as do the Apodes to the Malacopterygii. The single family, Mastacembelidae, is possibly derived from the Blenniidae.

Fresh and brackish waters of southern Asia and tropical Africa.

Sub-order XIII.—PEDICULATI

Air-bladder without duct. Opercle well developed, hidden under the skin; supraoccipital in contact with the frontals. Pectoral arch suspended from the skull; no mesocoracoid bone. Ventral fins, if present, jugular. Gill-opening reduced to a foramen situated in or near the axil more or less posterior to the base of the pectoral fin. Body naked or covered with spines or bony tubercles.

Connected with the Acanthopterygii Jugulares through the Batrachidae.

Families: Lophiidae, Ceratiidae, Antennariidae, Gigantactinidae, Malthidae.

Curiously aberrant marine fishes, many bathybial. The best known are the fishing-frog or angler, *Lophius*, and the *Antennarius*, which lives in coral groves or is carried about in mid-ocean among the *Sargassum* weeds.

SUB-ORDER XIV.—PLECTOGNATHI

Air-bladder without duct. Opercular bones more or less reduced; supraoccipital in contact with the frontals; maxillary and praemaxillary bones often firmly united. Pectoral arch suspended from the skull. No ribs. Ventral fins thoracic and much reduced if present; the pelvic bones, if present, more or less co-ossified. Gill-opening much reduced. Body covered with more or less osseous scales, bony scutes, or spines, or naked.

A highly aberrant group, closely connected with the Acanthopterygii through the Acanthuridae.

Division I. Sclerodermi.—Families: Triacanthidae, Triodontidae, Balistidae, Ostraciontidae.

Division II. Gymnodontes.—Families: Tetrodontidae, Diodontidae, Molidae.

The Plectognaths are all marine; the recently discovered Triacanthid *Halimochirurgus*, remarkable for its long, tube-like snout, from the Gulf of Manaar, is the only form of this sub-order which is confined to the deep sea. Although so highly specialized, several forms, such as *Ostracion* (the coffer-fish), *Tetrodon* and *Diodon*, were already represented in the upper Eocene. See FILE-FISH, GLOBE-FISH and SUN-FISH.

For bibliographical references to the Teleostomi, see ICHTHYOLOGY. (G. A. B.)

TELEPATHY (Gr. τῆλε, far, πάθη, feelings), or THOUGHT TRANSFERENCE, the conveyance of thoughts and feelings from mind to mind by other than the ordinary channels of sense. Although the word "telepathy" was first suggested by F. W. H. Myers in 1882, the suggestion had long before been made that the transmission of ideas, images and sensations could be brought about by other than the normally operative motor and sensory apparatus of the body. More than one writer had explained wraiths at the moment of death, clairvoyance and the phenomena of spiritualism by the theory of "brain waves." But it was not until the advent of the Society for Psychical Research that the hypothesis attracted much notice or was backed by carefully collected evidence. As used by the society the term is a mere designation, and implies no hypothesis as to "action at a distance" or the operation of any force not recognized by physical science.

The earliest recorded systematic experiments in thought transference were made in 1871 by the Rev. P. H. and Mrs. Newnham, and were continued for a period of some eight months with marked success; subsequent attempts showed no results of an evidential nature. A few years later the attention of the British Association was called to the subject by Prof. W. F. Barrett, and from 1881 onwards many experiments were made by members of the S.P.R. and others; in fact, the so-called "willing game" was at one time exceedingly popular; the successes, however, depended largely, if not entirely, upon muscle-reading, and usually ceased when there was no contact between agent (the sender of the idea) and percipient (the receiver). The systematic investigation has followed two main lines: (A) experiments on persons, often in the hypnotic state, in which the aim was to transfer selected images, &c., and compare the guesses with the results which chance would give; (B) the collection and examination of records of phenomena such as apparitions at the moment of death and other spontaneous cases in which there is a correspondence between the psychical states of two individuals, usually remote in space from one another. The problems raised by the two cases are entirely different: (1) in A there is seldom any hallucinatory element (see HALLUCINATIONS), in B, though not essential, it is present in a high percentage of cases; (2) what is transferred is in A an image kept before the mind, in B the phantasm of the dying person when that person has prima facie neither endeavoured to transfer this image nor, it may be, even thought of the percipient; (3) the desideratum in A has usually been to exclude normal methods of perception, in B the problem is to show that coincidence will not account for the facts; for, whereas in A the relation of successes to failures is known, in B it is difficult to get statistics and to be sure that an abnormal number of successful cases do not figure in a census. Side by side with direct experimentation, the S.P.R. collected first-hand records of apparitions at or within twelve hours of the moment of death. These, together with a discussion of the experimental evidence, were issued in 1885 under the title of *Phantasms of the Living*. In order to provide a statistical basis for discussion of coincidental apparitions, a census of hallucinations was undertaken by Edmund Gurney, and replies were obtained from over 5000 persons. A defect of the collection in *Phantasms* is that the progressive deterioration of evidence with age is neglected. No narratives are regarded as evidential by the society unless they were reduced to writing less than three years after the event or are based on notes made at the time.

The second systematic attempt to collect material was the census of hallucinations, initiated at the congress of experimental psychology of 1889, and entrusted to Professor Henry Sidgwick. The total number of persons who made returns was 17,000, of whom 1684 asserted that they had once or oftener experienced an hallucination. Analysis of the answers showed that in 350 cases the apparition was recognized; the probability that any person will die on a given day is roughly 1 in 19,000: if therefore chance alone operated, one apparition in 19,000 would coincide with a death; after making all allowances for error, the census committee found that 30 of the 350 recognized apparitions coincided with a death—in other words, cases prima facie telepathic were 440 times more numerous than chance coincidence would give. The committee reported that between deaths and apparitions of dying persons there exists a connexion which is not due to chance alone.

The experimental evidence for telepathy is made up partly of the results of trials where direct transference of thoughts, images or sensations was attempted, partly of successes in hypnotization at a distance; dreams (*q.v.*) also provide some material; and in a small but important class of cases, transitional between wraiths and ordinary experimental cases, the agent has caused his phantasm to appear to the percipient.

Among the chief experimenters may be mentioned Prof. M. Dessoir, Mr Guthrie, Sir Oliver Lodge and Prof. Sidgwick. In experiments conducted by the latter and Mrs Sidgwick at Brighton with numbers as the objects to be guessed, 617 trials were made with the agent and percipients in the same room: the numbers were between ten and ninety, and ninety successes were recorded, the probable total, if chance alone had operated, being eight. In a later series, conducted by Mrs Sidgwick, a similarly high proportion of successes was recorded; but when agent and percipients were in different rooms the results were not above what chance would give. These results were criticised by Prof. Lehmann and others, but were not seriously shaken; it was pointed out that the failure of experiments at a distance might be due to psychological causes rather than to the fact that the increase of distance eliminated the possibility of communication by normal means. In subsequent experiments, however, the successes in no series of any length were so far above chance as to give substantial support to a belief in telepathy.

Experiments in hypnotization at a distance provide some of the most conclusive evidence for telepathy. In 1885 trials were made both by Dr Janet and by Prof. Richet with the same subject. Out of twenty-five experiments the former held that nineteen were complete successes; Prof. Richet secured two successes and four partial successes in nine trials. The most striking point was that the hypnotic trance always coincided with or followed at an interval the attempt to hypnotize the patient; this is a feature of much importance in considering the possibility of coincidence or of auto-suggestion.

It is usually impossible to prove that a dying person has been thinking of the percipient; much less can we show that there was any idea of causing his phantasm to appear. There are, however, a small number of cases in which apparitions, of the agent or some other person, prima facie telepathic, have been produced experimentally. A singularly interesting instance is recorded by Wesermann, who tried the experiment in the early part of the 19th century; he wished to make the phantasm of a lady appear to a lieutenant, who was residing some miles away; at the time of the experiment he was, owing to an unforeseen visit, not alone, and his visitor is said to have seen the apparition also. More recently, in cases recorded in *Phantasms* and the *Census*, the figure of the agent himself has been seen by the percipient.

The so-called reciprocal cases are evidentially of much importance. Each of the two persons concerned appears to receive a telepathic impulse from the other, so that each receives information about the other, or sees his phantasm.

Occasionally telepathic impressions from animals to human beings are reported, but the facts are usually far from well established. Telepathic communication has also been suggested as the explanation of the simultaneous movements of large flocks of birds.

Various theories have been put forward to account for telepathy, but they only agree in the total lack of an experimental basis. Broadly speaking, they are divisible into physical and psychical. Sir W. Crookes suggests that transmission is effected by means of waves of smaller magnitude and greater frequency than those which constitute X rays. Undulations starting from nervous centres are adopted as the explanation by Prof. Flournoy and others. But Myers and others regard the case against a physical explanation as complete. The main difficulty in the way of it is that the strength of the impulse does not seem, in the spontaneous cases, to vary with the distance, as by all physical laws it should. On the other hand, a curious phenomenon has been noted in experiments; if the percipient gaze at an arrow with its head turned to the right, there is a tendency, disproportionately strong if we suppose that chance alone operates, for the arrow to be seen reversed. This fact is, however, more important in all probability for the light which it throws on the mechanism of hallucinations (*q.v.*) than on that of transmission. Telepathy is often invoked as an explanation of the facts of mediumship (see MEDIUM, and POSSESSION); but it seems insufficient to explain them unless we assume for the medium a far greater power of reading other people's minds than experimental evidence has so far shown to exist.

TELEPHONE (Gr. τῆλε, far, and φώνη, voice). Telephony is the art of reproducing sounds at a distance from their source, and a telephone is the instrument employed in sending or receiving such sounds. The term "telephony" was first used by Philipp Reis of Friedrichsdorf, in a lecture delivered before the Physical Society of Frankfort in 1861.[1] But, although this lecture and Reis's subsequent work received considerable notice, little progress was made until the subject was taken up between 1874 and 1876 by Alexander Graham Bell, a native of Edinburgh, then resident in Boston, Mass., U.S.A. Bell, like Reis, employed electricity for the reproduction of sounds; but he attacked the problem in a totally different manner. This will be better understood if we consider shortly on what the chief characteristics of sound depend.

Characteristics of sound.

The sensation of sound is produced by rapid fluctuation in the pressure of the atmosphere on the tympanum of the ear. If the fluctuations are irregular and non-periodic, the sound is called a noise; if they are cyclic and follow a regular and sufficiently rapid periodic law, the sound is musical. In connexion with the present subject it is important to notice the three characteristics of a musical sound, namely, *pitch*, *loudness* and *quality*. The pitch of a musical sound depends on the number of cycles passed through by the fluctuations of the pressure per unit of time; the loudness depends on the amount or the amplitude of the fluctuation in each cycle; the quality depends on the form or the nature of the fluctuation in each cycle. The necessary condition for a successful system of telephony is the ability to reproduce these characteristics.

Mechanical telephone.

In 1831 Wheatstone by his "magic lyre" experiment showed[2] that, when the sounding-boards of two musical instruments are connected together by a rod of pine wood, a tune played on one will be faithfully reproduced by the other. This only answers, however, for telephoning musical sounds to short distances. Another and somewhat similar example is furnished by what has been variously designated as the "string," "toy," "lovers," and "mechanical" telephone. Two disks of thin metal, or two stretched membranes, each furnished with a mouthpiece, are connected together by a thin string or wire attached at each end to the centres of the membranes. A good example may be made with two cylindrical tin cups; the bottoms form the membranes and the cups the mouthpieces. When the connecting string is held taut and sounds, such as those of ordinary speech, are produced in front of one of the membranes, pulses corresponding to the fluctuations of the atmospheric pressure are transmitted along the string and communicated to the other membrane, which in its turn communicates them to the air, thus reproducing the sound. In both these examples all the three characteristics—pitch, relative intensity, and quality—of sound are reproduced.

Page's discovery.

In July 1837 Dr C. G. Page of Salem, Mass., drew attention to the sound given out by an electromagnet at the instant when the electric circuit is closed or broken, and in October of the same year he discussed, in a short article[3] entitled "Galvanic Music," the musical note produced by rapidly revolving the armature of an electromagnet in front of the poles. Experiments bearing on this subject were subsequently made by a great number of investigators.[4] Page's discovery is of considerable importance in connexion with the theory of action of various forms of telephone, and was a very important feature in the early attempts by Reis to transit music and speech. On the 26th of August 1854 there appeared in *L'Illustration* (Paris) an interesting article by Charles Bourseul on the electric transmission of speech.[5] The writer recommended the use of a flexible plate at the source of sound, which would vibrate in response to the varying pressure of the air, and thus open and close an electric circuit, and of a similar plate at the receiving station, which would be acted on electromagnetically and thus give out as many pulsations as there are breaks in the current. These suggestions were to some extent an anticipation of the work of Reis; but the conditions to be fulfilled before the sounds given out at the receiving station can be similar in pitch, quality and relative intensity to those produced at the transmitting station are not stated, and do not seem to have been appreciated.

Bourseul's suggestions.

Reis's telephone.

In Reis's lecture an apparatus was described which has given rise to much discussion as to priority in the invention of the telephone. The instrument was described in over fifty publications[6] in various countries, and was well known to physicists previous to Bell's introduction of the electric telephone as a competitor with the electric telegraph. Reis caused a membrane to open and close an electric

circuit at each vibration, thus transmitting as many electric pulses through the circuit as there were vibrations in the sound. These electric pulses were made to act on an electromagnet at the receiving station, which, in accordance with Page's discovery, gave out a sound of a pitch corresponding to the number of times it was magnetized or demagnetized per second.

Reis's object was to reproduce at a distance not only music but also human speech; but that he did not wholly succeed is clear from the following extract from his lecture:—" Hitherto it has not been possible to reproduce human speech with sufficient distinctness. The consonants are for the most part reproduced pretty distinctly, but not the vowels as yet in an equal degree." Considering the time at which he wrote, Reis seems to have understood very well the nature of the vibrations he had to reproduce, but he failed to comprehend how they could be reproduced by electricity. His fundamental idea—the interruption of the current—was a fatal mistake, which was not at the time properly understood. The suggestion of Bourseul and the experiments of Reis are founded on the idea that a succession of currents, corresponding in number to the successive undulations of the pressure on the membrane of the transmitting instrument, could reproduce at the receiving station sounds of the same character as those produced at the sending station. Neither of them seemed to recognize anything as important except pitch and amplitude, and Reis thought the amplitude was to some extent obtained by the varying length of contact in the transmitting instrument. This might possibly be true to a small extent; but, considering the small capacity of the circuits he used and the nature of his receiving instrument, it is hardly probable that duration of contact sensibly influenced the result. The quality of the sounds was to some extent also reproduced; but, judging from the results of later telephone investigation, it is highly probable that this was due, not to the varying duration, but to the varying firmness of the contact.

Bell's researches.

The next worker at the telephone, and the one to whom the present great commercial importance of the instrument is due, was Bell. His aim was the production, by means of the undulations of pressure on a membrane caused by sound, of an electric current the strength of which should at every instant vary directly as the pressure varied.[1] His first idea seems to have been to employ the vibrations of the current in an electric circuit, produced by moving the armature of an electromagnet included in the circuit nearer to or farther from the poles of the magnet. He proposed to make the armature partake of the vibrations of the atmosphere either by converting it into a suitable vibrator or by controlling its vibrations by a stretched membrane of parchment

In the early trials the armature had the form of a hinged lever of iron carrying a stud at one end, which pressed against the centre of a stretched membrane. Fig. 1 shows the arrangement. M was a membrane stretched by a ring R over the end of a tube T fixed at one side of the frame F. To the opposite side of the frame an electromagnet I was fixed with its axis in line with the tube T, and between the end of the electromagnet and the membrane a hinged armature A was arranged in such a way that its motion could be controlled by the membrane. The instrument was joined in circuit with a battery and another similar instrument placed at a distance; and a continuous current was made to flow through the circuit, keeping the electromagnets energized. The experiments with this form were not successful, and, with the view of making the moving parts as light as possible, he substituted for the comparatively heavy lever armature a small piece of clock spring, about the size of a sixpence, glued to the centre of the diaphragm. The magnet was mounted with its end carrying the coil opposite, and very close to, the centre of the piece of clock spring. This answered sufficiently well to prove the feasibility of the plan, and subsequent experiments were directed to the discovery of the best form and arrangement of the parts. An increase in the size of the iron disk attached to the membrane augmented both the loudness and the distinctness of the sounds, and this finally led to the adoption of a thin iron disk supported round its edge, acting as both membrane and armature (fig. 2). Again, the form of the opening or mouthpiece in front of the membrane exercised considerable influence on the efficiency of the instrument, and it was ultimately ascertained that a small central opening, with a thin air space extending across the face of the membrane, was best. It was also found that comparatively small magnets were sufficient, and that there was no particular virtue in the closed circuit and electromagnet, but that a small permanent magnet having one pole in contact with the end of the core of a short electromagnet, the coil of which was in circuit with the line, but which had no permanent current flowing through it, answered the purpose quite as well.[2] The apparatus thus acted as both a transmitter and a receiver; indeed it is essentially the magneto-receiver which has come into universal use in practical telephony, though for transmission it was soon superseded by forms of microphonic transmitters. One of the latest forms of receiver, known as the double pole, is shown in fig. 3. M and M′ are two permanent magnets; P and P′ are soft iron pole-pieces upon which are placed the electromagnet coils C and C′; D is the diaphragm; I is a soft iron distance piece placed between the magnets at the end remote from the diaphragm; B is the brass body of the instrument, over which is placed a thin ebonite shell S. E is the ear-piece made of ebonite; F is a cap of the same material enclosing the receiver terminals, which are mounted upon the ebonite block G, attached to the distance piece I.

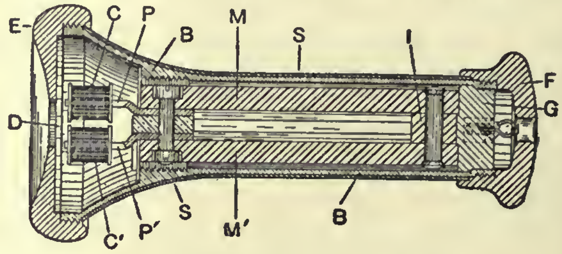

FIG. 3.—Double Pole Receiver.

Edison's instruments.

A telephone transmitter and a receiver on a novel plan were patented in July 1877 by Edison, shortly after the introduction of Bell's instruments. The receiver was based on the change of friction produced by the passage of an electric current through the point of contact of certain substances in relative motion. In one form a drum, mounted on an axis and covered by a band of paper soaked in a solution of caustic potash, was turned under a spring the end of which was in contact through a platinum point with the paper. The spring was attached to the centre of a diaphragm in such a way that, when the drum was turned, the friction between the point of the spring and the paper deflected the diaphragm. The current from the line was made to pass through the spring and paper to the cylinder. Now it had been previously shown by Edison that, when a current was made to pass through an arrangement like that just described, the friction between the paper and the spring was greatly diminished. Hence, when the undulating telephonic currents were made to pass through the apparatus, the constant variation of the friction of the spring caused the deflexions of the diaphragm to vary in unison with the variation of the electric

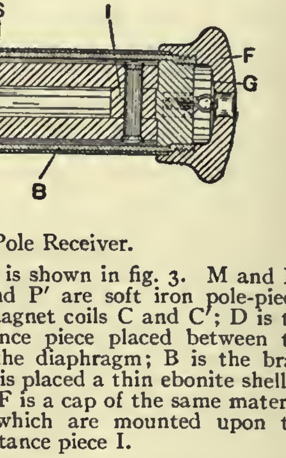

FIG. 4.—Edison's Microphone Transmitter.

[2] The extreme smallness of the magnets which might be successfully employed was first demonstrated by Professor Peirce of Brown University, Providence, R.I.

currents, and sounds were given out corresponding in pitch, and also to some extent in quality, with the sounds produced at the transmitting station. A cylinder of chalk was used in some of Edison's later experiments with this receiver.

The transmitter (fig. 4), in an early form, consisted of a cell of insulating material having at its bottom a flat-headed platinum screw G; on the top of G was a layer of carbon powder C, on the top of that a platinum disk D, and above that again, forming the cover of the cell, a disk of ivory B, held in position by a ring E. Resting on the centre of the ivory disk was a small piece of rubber tubing, and this was lightly pressed by the diaphragm A, which was held in place by the mouthpiece M. The varying pressure on A, when a sound was produced near it, caused corresponding variations in the pressure on the carbon powder, and this produced similar variations in its electric resistance.

Elisha Gray's experiments.

Experiments very similar to these of Edison were made by Elisha Gray of Boston, Mass., and described by him in papers communicated to the American Electrical Society in 1875 and 1878. In these experiments the electric current passed through the fingers of the operator's hand, which thus took the place of the spring in Edison's apparatus. The diaphragm was itself used as the rubbing surface, and it was either mounted and rotated or the fingers were moved over it. When the current passed, the friction was felt to increase, and the effect of sending a rapidly undulating current through the arrangement was to produce a sound. The application of this apparatus to the transmission of music was described by Gray.[1]

Dolbear's condenser telephone.

In another form of telephone, brought prominently forward by Professor A. E. Dolbear,[2] the effects were produced by electrostatic instead of electromagnetic forces, as in the Bell telephone. Sir W. Thomson (Lord Kelvin) observed in 1863[3] that when a condenser is charged or discharged, a sharp click is heard, and a similar observation was made by Cromwell F. Varley, who proposed to make use of it in a telegraphic receiving instrument.[4] In Dolbear's instrument one plate of a condenser was a flexible diaphragm, connected with the telephone line in such a way that the varying electric potential produced by the action of the transmitting telephone caused an increased or diminished charge in the condenser. This alteration of charge caused a corresponding change in the mutual attraction of the plates of the condenser; hence the flexible plate was made to copy the vibrations of the diaphragm of the transmitter. It is obvious that this apparatus might be used either as a transmitter or as a receiver, but that the effects must under ordinary circumstances be in either case extremely feeble.

Liquid transmitters of Bell and E. Gray.

It was very early recognized—and, indeed, is mentioned in the first patents of Bell, and in a caveat filed by Elisha Gray in the United States patent office only some two hours after Bell's application for a patent—that sounds and spoken words might be transmitted to a distance by causing the vibrations of a diaphragm to vary the resistance in the circuit. Both Bell and Gray proposed to do this by introducing a column of liquid into the circuit, the length or the resistance of which could be varied by causing the vibrations of the diaphragm to vary the depth of immersion of a light rod fixed to it and dipping into the liquid.

Berliner's microphone transmitter.

On the 4th of April 1877 Émile Berliner filed a caveat in the United States patent office, in which he stated that, on the principle of the variation with pressure of the resistance at the contact of two conductors, he had made an instrument which could be used as a telephone transmitter, and that, in consequence of the mutual forces between the two parts of the current on the two sides of the point of contact, the instrument was capable of acting as a receiver. The caveat was illustrated by a sketch showing a diaphragm with a metal patch in the centre, against which a metal knob was lightly pressed by an adjusting screw. This seems to have been the first transmitter in which it was proposed to use the resistance at the contact of two conductors.

Edison's microphone transmitter.

Almost simultaneously with Berliner, Edison conceived the idea of using a variable resistance transmitter.[5] He proposed to introduce into the circuit a cell containing carbon powder, the pressure on which could be varied by the vibrations of a diaphragm. He sometimes held the carbon powder against the diaphragm in a small shallow cell (from a quarter to half an inch in diameter and about an eighth of an inch deep), and sometimes he used what he describes as a *fluff*, that is, a little brush of silk fibre with plumbago rubbed into it. In another form the plumbago powder was worked into a button cemented together with syrup and other substances. In the specification of the patent applied for on the 21st of July 1877 he showed a sketch of an instrument which consisted of a diaphragm, with a small platinum patch in the centre for an electrode, against which a hard point, made of plumbago powder cemented together with india-rubber and vulcanized, was pressed by a long spring, the pressure of the carbon against the platinum disk being adjusted by a straining screw near the base of the spring. Subsequently he filed an application for a patent in which various forms of springs and weights assisted in maintaining the contacts and otherwise improved the instrument.

Hughes's microphone.

In the early part of 1878 Professor D. E. Hughes, while engaged in experiments upon a Bell telephone in an electric circuit, discovered that a peculiar noise was produced whenever two hard electrodes, such as two wires, were drawn across each other, or were made to touch each other with a variable degree of firmness. Acting upon this discovery, he constructed an instrument which he called a "microphone,"[6] and which consisted essentially of two hard carbon electrodes placed in contact, with a current passing through the point of contact and a telephone included in the same circuit. One of the electrodes was attached to a sounding board capable of being vibrated by sound-waves and the other was held either by springs or weights in delicate contact with it. When the sounding board was spoken to or subjected to sound-waves, the mechanical resistance of the loose electrode, due to its weight, or the spring, or both, served to vary the pressure at the contact, and this gave to the current a *form* corresponding to the sound-waves, and it was therefore capable of being used as a speaking-telephone transmitter.[7]

The next transmitter of note was that introduced by Francis Blake, which came into wide use in the United States of America and other countries. In it the electrodes were of platinum and carbon.

To a frame F (fig. 5) was attached a diaphragm D of thin sheet iron; in front of this was a cover M, M provided with a suitable cavity for directing the sound-waves against the diaphragm. The microphonic arrangement consisted of a spring S, about the hundredth of an inch thick and the eighth of an inch broad, fixed at one end to a lever L, and carrying at its free extremity a brass block W. In one side of W a small disk C of gas carbon was inserted, resting on the hemispherical end of a small platinum pin K, about the twentieth of an inch in diameter, held in position by a thin spring A. The pressure of the carbon on the platinum point could be adjusted by the screw N, which turned the lever about the flexible joint G. The electrical connexions of the instrument as arranged for actual use are also illustrated in the figure. The current circuit went through S, W, C, K, A, and the primary circuit of the induction coil I to the battery B, and thence to S again. This formed a local circuit at the transmitting station. The line of circuit passed through the secondary of the induction coil I to the line, from that to the telephone T at the receiving station,

and then either to earth or back to the induction coil by a return line of wire.

Another type of microphone which was used in Europe much more than in the United States was the multiple-contact instrument. In this several microphonic joints were employed.

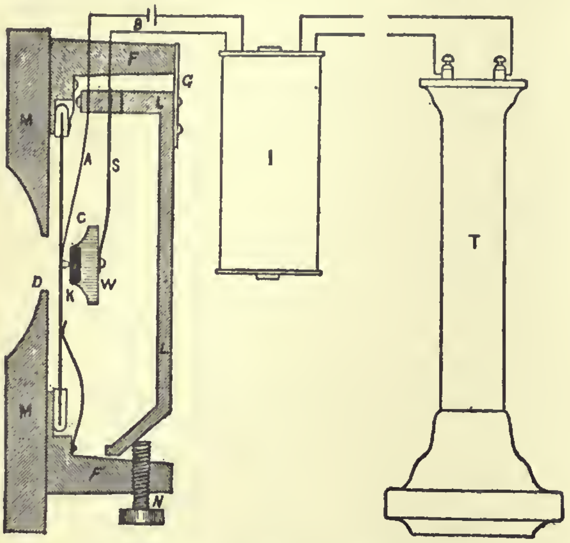

FIG. 5.—Blake's Transmitter.

Thus, in the Crossley transmitter four hard carbon pencils were arranged in a lozenge-shaped figure, the ends of each pencil resting loosely in a small carbon block. These blocks were fastened to a diaphragm of wood. The circuit connexions were such that two adjacent sides of the lozenge were in parallel and two in series. In the Ader transmitter as many as twelve carbon pencils were employed, arranged in a series of two groups with six pencils in parallel in each group. These were supported at their ends in parallel carbon bars, which were carried by a nearly horizontal wooden diaphragm. Such multiple-electrode transmitters give a loud although somewhat harsh sound, and will bear being spoken to very strongly without breaking the circuit.

A type of transmitter which has come to be invaluable in connexion with long-distance telephony, and which has practically superseded all other forms, is the granular carbon transmitter. The earliest instrument of this kind was the Hunnings transmitter, patented in 1878. This was constructed of a shallow box placed in a vertical position, with metallic front and back and insulating sides. The front face was of thin metal, and served as a diaphragm. The box was filled nearly, but not quite full, of granulated hard carbon. The current from the battery used passed from the diaphragm through the granulated carbon to the metallic back of the box. When spoken to the diaphragm vibrated, and thus set the carbon granules into vigorous vibration. The vast number of microphonic contacts present give rise to very strong electrical undulations, and hence to a loud sound.

The chief difficulty with this transmitter, and with various others of later date based upon it, has been the frequent packing of the carbon granules, which renders the instrument inoperative. The difficulty was first satisfactorily overcome in the long-distance transmitter, invented by A. C. White in the laboratory of the American Bell Telephone Company, and commonly known as the "solid back transmitter" (fig. 6).

The microphonic portion of the transmitter is contained in a thin cylindrical box or case of brass A, the inner curved surface of which is covered with an insulating layer of paper. The case is firmly fixed to a "bridge" B with its back or bottom in a vertical position. To the brass bottom of the case is attached a thin disk of polished hard carbon C, which is slightly less in diameter than the brass bottom, so that the carbon disk almost entirely covers this brass back, leaving only a slight annular space around its edge. The front or cover of the case is a similar button of hard polished carbon D, also slightly smaller in diameter than the cylindrical wall of the box. It is attached to a brass disk E, which is fastened to the centre of the diaphragm F by means of a rivet, and is capable of moving to and fro like a plunger when the diaphragm vibrates. A washer of thin flexible mica G concentric with the carbon button is carried by the brass disk, and projecting over the edge of this is held firmly against the rim of the cylindrical wall of the case by an annular brass collar H, which is screwed upon the outer curved surface of this wall. The box is thus entirely closed at the front, while the front carbon disk, which constitutes an electrode, is perfectly free to follow the motions of the diaphragm.

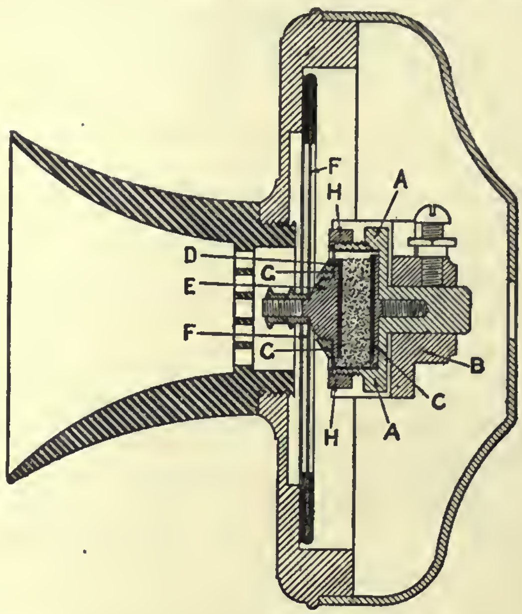

FIG. 6.—Solid Back Transmitter.

The space enclosed between the front and rear faces of the box is filled about three-quarters full of finely granulated hard carbon, which therefore lies in contact with the front and rear carbon disks of the apparatus, and also fills up the space lying between the lower edge of these disks and the curved surface of the case. The current from the battery passes from one of the carbon disks to the other through the particles of granulated carbon which fill the space between them.

The disks and granules constitute a very powerful microphone. The motions impressed upon the carbon granules are very vigorous, and this together with the particular arrangement of the parts of the instrument is effectual in obviating the difficulty from packing which attended the use of earlier forms of granulated carbon transmitters. This instrument has almost entirely displaced all other forms of transmitter.

Subscribers' Organization.—The employment of the telephone as one of the great means of communication requires a definite organization of the subscribers. It is not practicable to connect each subscriber directly to all the others, hence a system of exchanges has been adopted. The territory in which a telephone administration operates is usually divided into a number of local areas, in each of which one or more exchanges are placed. An exchange is a central station to which wires are brought from the various subscribers in its neighbourhood, any two of whom can be put in telephonic communication with each other when the proper pairs of wires are joined together in the exchange.

When the subscribers in a local area exceed a certain number, or when for some other reason it is not convenient or economical to connect all the subscribers in the area to one exchange, it is usual to divide the area into a number of districts in each of which an exchange is placed, and to connect these district exchanges together by means of "junction circuits." In some cases the exchanges are connected together directly; but when the volume of traffic is not sufficient to warrant the adoption of such a course connexions between two exchanges are made through junction centres to which both are connected.

A system of wires, similar to that which connects the district exchanges in an area, links together the various local areas in the territory, and sometimes the territory of one administration with that of another. These inter-area or long-distance lines, called trunk circuits in England, terminate at one exchange in each local area, and between that exchange and the various district exchanges junction circuits are provided for the purpose of connecting subscribers to the trunk lines.

Circuit and Working Arrangements.—The method first employed for working a telephone line was extremely simple. A single line of wire, like an ordinary telegraph line, had a Bell telephone included in it at each end, and the ends were put to earth. Words spoken to the telephone at one end could be heard by holding the telephone to the ear at the other. To obviate the inconvenience of placing the telephone to the mouth and the ear alternately, two telephones were commonly used at each end, joined either parallel to each other or in series. The contrivance most generally adopted for calling attention was a call-bell rung either by a small magneto-electric machine (magneto-generator) or by a battery. The telephone was switched out of circuit when not in use and the bell put in its place, a key being used for throwing the battery into circuit to make the signal. This arrangement is still employed, a hook being attached to the switch lever so that the mere hanging up of the telephone puts the bell in circuit. In some cases when a magneto-generator is employed for calling purposes the coil of the machine is automatically cut out of circuit when it is not in action, and is brought into circuit when the handle is turned by the operation of a centrifugal or other arrangement.

At first it was usual to join the microphone transmitter in the direct circuit. It was soon found that it could only be used to advantage in this way when the total resistance of the circuit, exclusive of the microphone, was small compared with the resistance of the microphone—that is, on very short lines worked with

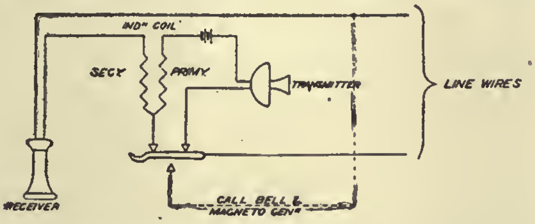

FIG. 7.—Telephone Set with Transmitter in a Local Circuit.

low resistance telephones. The transmitter on long and high-resistance lines worked better by joining, in the manner shown in fig. 7, the microphone, a battery and the primary of an induction coil in a local circuit, and putting the line in circuit with the secondary of the induction coil, which acted as the transmitter. The resistance of the microphone can thus be made a large fraction of the total resistance of the circuit in which it is placed; hence by using considerable currents, small variations in its resistance can be made to induce somewhat powerful currents in the line wire. The requisite energy is derived from the battery.

In the earliest telephone switchboards the lines were connected to vertical conducting strips, across which were placed a series of similar horizontal strips in such a manner that any horizontal could be connected to any line strip by the insertion of a plug into holes provided in the strips for the purpose. Any two lines could be connected together by connecting both to the same horizontal strip.

The next step of importance was the introduction of what was termed the "Standard board." This board was equipped with spring-jacks and annunciators (calling-drops) for the subscribers' lines, and with flexible cords terminating in plugs for connecting purposes. The spring-jack used was a form of switch with two contact springs which pressed against each other, one being connected to the subscriber's line wire and the other to the annunciator, which was also earthed. When a plug was inserted in the spring-jack the connexion between the springs was opened, disconnecting the calling-drop from the line. Each connecting-cord circuit had associated with it a clearing-out drop connected between the cord and earth and a key by means of which the operator's speaking and ringing apparatus could be brought into circuit. When a subscriber called (by turning the handle of his magneto-generator), the shutter of the annunciator associated with his line dropped. This attracted the attention of the attendant, who in response to the call inserted a plug into the spring-jack and connected the speaking apparatus to the circuit by means of the key. Then, having obtained particulars of the subscriber's requirement, the operator connected the second plug to the spring-jack of the wanted subscriber, whom she rang up. When the conversation was finished either of the subscribers could release the shutter of the clearing-out drop by turning his generator handle, and the operator thus notified of the fact removed the plugs and discontinued the connexion.

The single-wire earthed circuits used in the early days of telephony were subject to serious disturbances from the induction caused by currents in neighbouring telegraph and electric light wires, and from the varying potential of the earth due to natural or artificial causes. The introduction of electric tramways caused an enormous increase in disturbances of this class. It was early recognized that a complete metallic circuit would obviate troubles from varying earth potentials, and that if the outgoing and incoming branches of the circuit were parallel and kept, by transposition spiralling, or otherwise, at equal average distances from the disturbing wire, induction effects would likewise be removed. These advantages led to the gradual supersession of the single-wire system until at the present day the all-metallic system is employed almost universally. Since the time when the system first became prominent all switchboards have been arranged for metallic circuits.

Though many types of manually operated switchboards have been brought into use, differing from each other in respect of circuit and working arrangements, yet each of them may be placed in one or other of three main classes according as the system of working is magneto, call-wire, or common battery. The fundamental principle of the magneto system has been described in connexion with the "Standard board."

In a large exchange a number of operators are necessary to attend to calls. Several single switchboards like that described may be employed, each devoted to a certain section of the subscribers, and placed in care of an operator. In these circumstances, when, as frequently will be the case, the person calling desires to be put in communication with a subscriber who belongs to another section, connexions must be established in the office between the two sections; this necessitates additional switchboard arrangements, and also increases the time required to put subscribers in communication with one another. The difficulty was obviated by the introduction of the "multiple switchboard." This board is built up in sections of one or more operators' positions each. All the subscribers' lines are connected in order to jacks on the first two or three or four operators' positions, and these connexions are repeated or "multipled" upon each succeeding similar group of positions. Each subscriber's circuit is further connected to another spring-jack directly associated with the calling-drop. These spring-jacks, known as answering jacks, are distributed along the switchboard, a certain number being terminated upon each position and placed in the care of the operator assigned to that position. Hence this operator, when signalled in the ordinary way, can put any one of these subscribers in connexion with any subscriber whatever, without the necessity of calling upon another operator to make connexions.

Two methods of "multipling" have been much used. In the arrangement first introduced the line wire is connected in series through the various spring-jacks, the circuit finally passing through the answering jack to the calling-drop. This arrangement is liable to give trouble, as disconnexions may arise in the spring-jacks in consequence of the failures of the springs to make contact. Operating mistakes also cause interruptions to conversations, as it is possible, by the insertion of a plug in a multiple jack, to disconnect the circuit between two talking subscribers. To overcome these difficulties the "branching multiple" was introduced. In this arrangement, instead of the circuit being made through the jacks in series, each jack is connected to an independent branch from the main circuit. With the "branching multiple" the "self-restoring drop" was introduced. This apparatus has two coils, one of which, connected across the line, is provided for the purpose of projecting the shutter, while the other is intended for its restoration and is joined in a local circuit arranged to be closed when a plug is inserted in any one of the associated jacks.

It is necessary that the operators working at a multiple board shall be able to ascertain without entering a subscriber's circuit whether the circuit be disengaged. This requirement is usually met by connecting a third or "test" wire to each of the jacks associated with a subscriber's line, and by making the circuit arrangements such that this wire is either disconnected or at earth potential when the line is not in use, and at some potential above or below that of the earth, when the circuit is engaged. With a proper arrangement of the operator's speaking set it is possible, by touching the socket of a jack with the tip of a peg or a special "test" thimble, to determine whether the circuit connected to the jack is in use.

Both the series and the branching methods of multipling are recognized at the present time as standard methods, although the former is only employed in comparatively small exchanges. The magneto system itself is dying out. There are still many magneto exchanges in existence, but when new exchanges are erected only the very smallest are equipped for magneto working, that system having succumbed to the common battery one in the case of all equipments of moderate and large dimensions.

The "call-wire" system has been used to some extent, but it is now obsolete. The feature of the system was the provision of special service circuits, termed call-wires, for purposes of communication between the subscribers and the exchange operators. Each subscriber was given the exclusive use of a circuit as in other systems, and shared a call-wire with a number of other subscribers. Each telephone set was equipped with a special key or switch by means of which the telephone could be transferred from an exclusive line to the call-wire at will. A subscriber desiring a connexion pressed the key and communicated his own number and that of the wanted subscriber to the operator in attendance on the call-wire. Then, when the connexion was made, the originating subscriber rang up the other. At the close of a conversation the originating subscriber again entered the call-wire and requested the operator to take down the connexion. The call-wires were usually equipped with drops in order that the exchange might be called at night when the operators were not listening continuously.

One of the greatest advances made in the development of the art of telephony was the introduction of the "common battery relay system." This advance did not merely remove the primary batteries from the subscribers' stations; it removed also the magneto-generator, and at the same time it modified considerably the conditions governing the exchange operating. The calling-drop of the magneto system was displaced by a relay and a small electric incandescent lamp, and whereas in the older system the calling-drop and the answering jack with which it was associated were some distance apart, the calling-lamp and the answering jack of the newer system were placed in juxtaposition. This alteration improved the operating conditions in three ways. In the first place it increased the visibility of the signalling instrument; in the second place it brought that instrument into the position in which it could most readily catch the operator's eye; and finally it eliminated the effort involved in associating one piece of apparatus with another and in finding that other. Moreover the clearing-out drop of the cord circuit was replaced by an arrangement which included the provision of one signal to be controlled through the agency of a relay by the calling subscriber, and another to be controlled by the person wanted. These supervisory signals took the form of lamps and were placed on the keyboard in positions immediately adjacent to the associated cords. With the adoption of relays the signalling between the subscribers and the exchange became automatic, and, with the introduction of the principle of double and automatic supervision on the cord circuits, it became possible for the operators to tell at any instant the state of a connexion. As a result the time occupied by an operator per call was reduced from 50·77 seconds to 16·63 seconds.

Three fundamental common battery transmission systems have been devised and are shown in figs. 8, 9 and 10. In the Hayes system (fig. 8) a repeating coil is placed in the cord circuit, and when two subscribers are connected together the winding connected to the line of the subscriber who is talking for the time being acts as primary, and the other, which is in the line of the listening subscriber, as secondary.

variation in resistance of the transmitter spoken into causes a variation of the pressure at the line terminals of the impedance coils, and since those terminals are common to the two circuits the variable E.M.F. operates in the line of the listening subscriber, causing the reproduction of the speech in the latter's receiver. The Stone system, compared with that of Hayes, possesses the

disadvantage that one of the conditions affecting the supply of current to any particular subscriber's circuit is the resistance of the

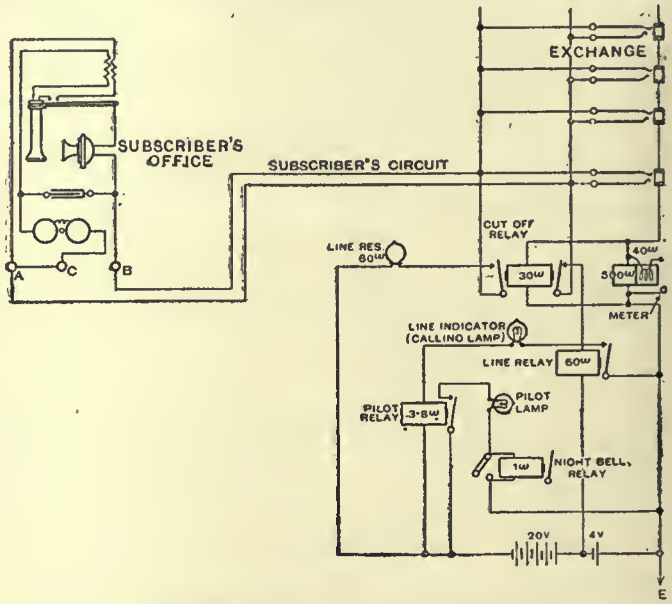

FIG. 11.—Subscriber's Circuit, Common Battery System.

other circuit to which it is connected for the time being. An improvement in this respect has been effected by the insertion of condensers in the cord circuits, coupled with the use of two sets of impedance coils, one set on each side of the condensers.

Dean's method (fig. 10) embodies the idea of supplying current to the transmitters over the line wires in parallel instead of round the loop circuit, as in the other systems referred to. An earth return is used. The transmitter is placed in multiple with the primary winding of an induction coil whose secondary operates in the loop circuit, and consequently when the transmitter is spoken into, a variable E.M.F. is impressed upon the circuit through the medium of the induction coil. The impedance coils shown connected between the battery and the lines and between the latter and the transmitters are joined up non-inductively as regards the transmitter circuits, but inductively as regards the secondary circuits. Figs. 11 and 12 indicate typical subscriber's and connecting-cord circuits as equipped by the Western Electric Company. At the subscriber's station when the receiver is on the hook switch the circuit is through the call-bell and a condenser. The conditions permit of the circulation of the alternating currents of low periodicity, which are used for operating the bells, but in respect of the battery the circuit is open until the subscriber lifts the receiver, when the hook switch, thus released, joins the transmitter with one winding of an induction coil in series across the circuit. A current then flows and in passing round the circuit operates the line relay, with the result that the calling-lamp is lighted. The operator, whose attention is thus attracted, inserts a peg in the jack, then throws over the speaking key of the cord circuit, and having ascertained particulars of the requirement places the other peg of the pair in the nearest multiple jack of the wanted subscriber, whom she proceeds to ring up. In the meantime the calling-lamp has darkened; and each subscriber's line being equipped with a cut-off relay whose function it is to disconnect the calling apparatus while the circuit is in use, the insertion of a peg is immediately followed by the disappearance of the calling signal. The supervisory lamp associated with the peg in the wanted subscriber's jack glows from the time that the peg is inserted until the subscriber responds, when it darkens, in which condition it remains until the subscriber restores the receiver to the hook and causes the lamp to light up again. The other supervisory lamp on the cord circuit is controlled in a similar manner by the subscriber who originated the call, and as that subscriber's telephone is off the hook when the peg is inserted, the lamp is not lighted at all until the subscriber replaces the receiver. When both lamps glow, the operator, who thereby knows that both subscribers have restored their instruments, discontinues the connexion.

A cord circuit, similar in many respects, including the method

FIG. 12.—Typical Cord Circuit, Western Electric Co.'s System, No. 1 Exchanges.

of operation, but equipped with condensers and impedance coils, in place of the repeating coil, is shown in fig. 13.

In fig. 11 a meter or counter is shown associated with the subscriber's line, and in both figs. 12 and 13 position meters are shown connected to the cord circuits. The operation of these meters is controlled by the operators. The subscriber's meter is joined in multiple with the cut-off relay, and whenever a peg is connected to the circuit a current flows through the meter. This current is small, however, and the meter is not operated until a much larger current is passed through it. Calls are registered by pressing a key, which connects a battery through a position meter of very low resistance to the socket of the line jack, thereby furnishing the necessary energy to the meter. The position meter just mentioned is common to all the cords on one position and records all completed calls handled at the position. Some administrations, in addition to employing the ordinary position meter, use a second one for registering ineffective calls.

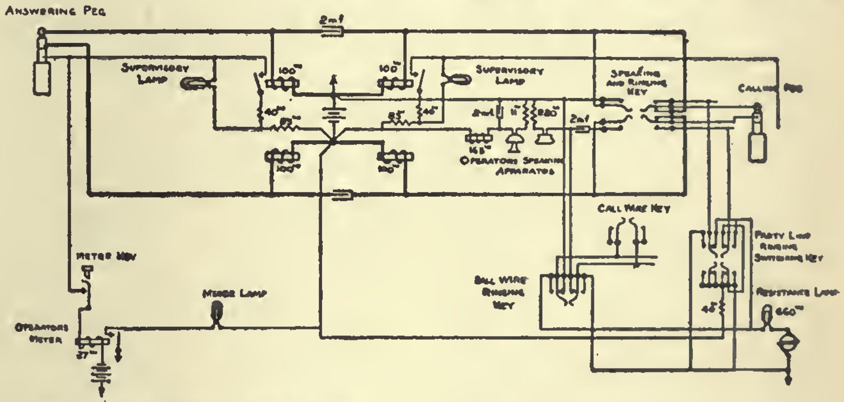
In large towns served by a number of exchanges the junction equipment is an important feature. In many cases from 60 to 80 per cent. of the calls originated at an exchange are for subscribers connected to other exchanges, and in these cases the junction plant forms a considerable fraction of the whole equipment. Moreover each call junctioned is dealt with by at least two operators. The junction circuits connecting two exchanges are invariably divided into two groups, one for traffic from exchange A to exchange B, the other for traffic from B to A. At the outgoing end the circuits are multipled on the subscribers' switchboard, while at the incoming end they terminate in plugs on a special incoming junction switchboard upon which the subscribers' lines are multipled in the usual way.

When a subscriber at exchange A asks for a connexion to a subscriber at B, the operator at A, to whom the request is made, passes the particulars over an order wire to an operator at B. The latter names a disengaged junction circuit, then "tests" the line of the wanted subscriber, and if she finds it free, finally completes the connexion and rings the subscriber. During the progress of these operations the A operator connects the originating subscriber to the junction circuit named by the B operator. There is only one signal on the cord circuit at B, and that signal is controlled by exchange A. Each of the subscribers controls a signal at A, and when either or both of the telephones are replaced, the action is indicated by the lamps there. Control of the call is thus vested in the operator at the originating exchange, at which point the connexion must be severed before a clearing signal can appear at B.

Party Lines.—A circuit which serves more than one subscriber is termed a "party line." It was originally the practice to place the calling apparatus in series in the line circuit, but the effect of the large impedance introduced by the electromagnets of the calling bells was such that not more than two or three persons could be connected without seriously impairing the efficiency of the circuit for speech transmission. An improvement was effected in this respect by the introduction of the "bridging" system, in which the bells possessing high inductance are placed in parallel between the two wires of the circuit. Although the bells are constantly in circuit their high impedance prevents any appreciable interference with the telephonic currents. In America, on farmers' circuits, ten or more stations are frequently connected to one line; but in England ten is practically the maximum. In city districts the modern practice is to restrict the number to four stations per line, and to equip the exchanges and stations for selective ringing. In one arrangement, now in extensive use, each telephone set is fitted with a relay of high inductance which is bridged across the circuit in series with a condenser. When the relay is operated it connects a bell between one of the wires of the circuit and earth, while the bell itself is arranged to respond to current pulsations in one direction only. The four telephones on a circuit are so wired that the relays connect two of the bells between each wire and earth, and further that one of each pair of bells responds to positive and the other to negative pulsations. This system of course requires that the exchange equipment shall include machines capable of delivering a positive pulsating current and a negative pulsating current, besides the usual alternations required for the ringing of ordinary subscribers.

In another party line system a harmonic principle is employed: the ringing machines deliver alternating currents of four frequencies, while each bell is constructed to operate at a particular frequency only. Of the four bells connected to a circuit each responds to a different frequency.

Trunk Line Working.—Trunk or long-distance working is complicated by the necessity for recording all calls. The system of the British Post Office is worked as follows: A subscriber desiring a long-distance connexion calls up his local exchange in the ordinary way, and the operator there, being informed that a trunk connexion is desired, extends the subscriber's line to the Post Office by means of a record circuit. At the Post Office a record operator replies and takes particulars of the connexion, and these are entered upon a ticket. The record operator then removes her speaking apparatus from the circuit, and the local operator, receiving a disconnect signal, severs the connexion at the local exchange. Meanwhile the ticket is conveyed to the position where the lines to the town wanted are terminated. If there be a line free, or when the turn of the call is reached, particulars of the connexion wanted are passed to the distant end, and the trunk operators request the local exchanges to connect the subscribers by means of junction



From the *Post Office Electrical Engineers' Journal.*

FIG. 13.—Typical Cord Circuit, British Insulated Co.'s System.

circuits to the trunk exchanges where the necessary connexions are made between the trunk line and the junctions. The call is controlled by the trunk operators, the junction circuits being equipped in such a manner that the subscribers' signals appear at the trunk exchanges, from which point disconnecting signals are sent automatically to the local exchanges, when the connexions between the trunk and the junction circuits are removed.

The large modern trunk exchanges are equipped with relays and lamps for signalling purposes. "Calculographs" are employed for stamping the time upon the tickets, and there is associated with each trunk circuit a device which lights a lamp as soon as the scheduled limit of the period of conversation is reached.

Particulars of calls are now passed between trunk centres to a great extent over telegraph circuits superposed upon the trunk lines. This arrangement permits particulars of calls to be passed over lines while conversations are in progress.

Automatic Systems.—The idea of automatic telephony is to substitute for the operator of the manual exchange an electro-mechanical or other switching system, which, controlled in its movement by the action of the subscriber, will automatically select, connect and disconnect circuits as desired. Several schemes embodying this idea have been developed, and one of them has been put into extensive operation. Each subscriber's circuit on this system terminates upon the incoming portion of a selector switch, called a first selector, and is multipled upon the outgoing portions of a number of similar switches called connector switches. Only calls originated by a subscriber pass through the selector switch (first selector) provided for his sole use; the calls incoming to him pass through one or other of the various connector switches upon which his circuit is multipled. Each connexion involves the use of three switches, viz., a first selector, a connector switch, and a second selector which is brought into operation between the other two.

The subscribers' lines in an exchange are arranged in groups of 1000, which are divided in turn into sub-groups of 100 each. By means of his first selector the circuit of a calling subscriber is connected to the outgoing end of a junction whose other end terminates upon the incoming portion of a second selector in the thousand group to which the wanted subscriber belongs. The second selector in turn extends the connexion by means of another junction circuit to one of the connector switches in the hundred group wanted, while finally the connector switch completes the connexion. One hundred circuits are connected to the outgoing portion of each switch, and the contacts upon which they terminate are arranged in a number of horizontal rows upon the face of a curved surface, at whose axis a vertical shaft is placed. This shaft, which carries a set of "wipers" connected to the incoming circuit, is susceptible of a vertical and a rotational movement, so that the wipers may be brought, first opposite any particular horizontal series of contacts, and then into actual contact with any particular set in the series. The movements of the shaft are controlled by relays and electro-magnets which operate in response to the action of the subscriber whose telephone is fitted with a calling mechanism which, when the subscriber calls, earths the line a certain number of times for each figure in the number of the wanted subscriber.

Wire Plant.—In suburban and rural districts subscribers are usually served by means of bare wires erected upon wooden or iron poles. As subscribers' lines are invariably short, the smallest gauge of wire possessing the mechanical strength necessary to withstand the stresses to which it may be subjected can be employed, and bronze wire weighing 40 ℔ per mile is commonly used. In large towns telephone distribution by means of open wires is practically impossible, and the employment of cables either laid in the ground or suspended from poles or other overhead supports is necessary.

In the types of cable that were first used, the wires, usually with a cotton insulation, were drawn into lead tubes, and the tubes filled with paraffin or other similar compound, which kept the wires from the injurious effects of any moisture which might penetrate the lead tube. This form of cable has been superseded by a type with paper insulation. The separate wires are surrounded only with a loose covering of specially prepared paper, which furnishes abundant insulation. In the manufacture of the cable the wires are first enclosed in the paper, which is applied sometimes longitudinally and sometimes spirally. The conductors are then twisted in pairs with definite lays. These pairs are laid up symmetrically into cables, each layer being protected with an additional covering of paper and all adjacent layers revolving with an opposite twist. The cable is then placed in an oven, and, after all moisture has been driven off, it is passed through a lead press whence it emerges protected by a continuous lead pipe. The electrostatic capacity of a cable of this type is low, and its dimensions are small, the external diameter of a cable containing 1600 ten-℔ conductors being only 2¾ in. The conductors used for subscribers' circuits are of copper weighing from 10 to 20 ℔ per mile. Junction circuits are usually made up of 20 or 40 ℔ conductors.

When a number of cables follow the same route, they are generally laid in conduits made up of earthenware or cement ducts; iron pipes are used when the number of cables is small. Manholes are placed at intervals in the line of ducts to facilitate the drawing in and jointing of the cables, and surface boxes are placed in the footways for distributing purposes. Various methods of making the connexions between the large main cables and the subscribers are in use. In one system the main cables terminate in large air-tight iron boxes placed in the manholes. There, the large cables divide into a number of small cables, which are carried along the footways in pipes and are tapped at suitable points to serve subscribers. Another method of distribution, largely adopted, is to run the lead cables into the interior of blocks of buildings, and to terminate them there in iron boxes from which the circuits are distributed to the surrounding buildings by means of rubber-covered wires run along the walls. Aerial distribution from distributing poles is a method frequently adopted. In this case the cables terminate upon the poles, the connexions between the cable wires and the open wires being made with rubber-covered leads.

The introduction in 1883 of the hard-drawn copper wire of high conductivity invented in 1877 by T. B. Doolittle was of the greatest importance in rendering the use of long lines practicable, and it is universally employed for such service. Wire weighing between 150 and 400 ℔ per mile is generally used. The New York-Chicago line, built in 1892, is of wire 165 millimetres in diameter (No. 8 Birmingham), weighing 435 ℔ per mile and having a resistance of 2·05 ohms per mile. Speech has been habitually transmitted for business purposes over a distance of 1542·3 m., viz., over the lines of the American Telegraph and Telephone Company from Omaha to Boston. Conversation has been carried on over 2200 m. of No. 8 line.

As no practical process of telephone relaying has been devised, it is extremely important that the character of the line should be such as to favour the preservation of the strength and form of the telephone current. In circuits possessing high resistance and capacity and low inductance per mile, telephonic currents are rapidly attenuated, and the higher the frequency the more rapid is the attenuation. Moreover, as the velocity of propagation is a function of the frequency, there is distortion of the complex waves. Oliver Heaviside showed mathematically that uniformly-distributed inductance in a telephone line would diminish both attenuation and distortion, and that if the inductance were great enough and the insulation resistance not too high the circuit would be distortionless, while currents of all frequencies would be equally attenuated. Following up this idea, Professor M. I. Pupin showed that by placing inductance coils in circuit, at distances apart of less than half the length of the shortest component wave to be transmitted, a non-uniform conductor could be made approximately equal to a uniform conductor. Many circuits have been "loaded" in the manner proposed by Pupin during recent years, especially in underground cables, and it has been found in practice that the transmission value of these when loaded is approximately from three to four times their value unloaded. Open aerial long-distance lines have also been loaded, but not to the same extent. The introduction of inductance coils into such circuits renders them more susceptible to trouble from atmospheric electricity and more sensitive to leakage variations.

In consequence of their high capacity, the attenuation constant of submarine cables is high, and only a small number of cables, of comparatively short length, are in use for telephonic purposes. Attempts have been made to improve submarine cables in this respect, and in 1906 a short cable "loaded" with Pupin coils was laid across Lake Constance. The problem, however, of constructing a deep-sea cable satisfactorily, with suitable inductance coils inserted at short distances apart, is a difficult one, and one which it cannot be said has been solved. (H. R. K.)

Commercial Aspects.—The records of the telephone industry in Great Britain during the thirty years from 1877 to 1907 form an instructive chapter in the industrial history of the country. The aspects which stand out most prominently in this history are: (*a*) The vacillation of successive governments due to the conflicting policies adopted from time to time to protect the telegraph revenues of the Post Office and to avoid the suppression of an enterprise which was becoming a public necessity and yielding substantial royalties to the Postmaster-General. (*b*) The obstructive use made by the local authorities of their power to veto underground wayleaves. (*c*) The remarkable success achieved by the National Telephone Company, despite these obstacles, in developing an extensive organization and a profitable business.

The chief events in chronological order are:—

1876. Graham Bell's telephone patent was granted for the United Kingdom.

1877. Edison's telephone patent was granted for the United Kingdom.

1878. Professor D. E. Hughes invented the microphone, but did not apply for letters patent. The Telephone Company, Limited, was formed to acquire Bell's patent. During the passage of the Telegraph Bill 1878 through parliament the Postmaster-General endeavoured, without success, to insert a clause declaring that the term "telegraph" included "any apparatus for transmitting messages or other communications with the aid of electricity, magnetism, or any other like agency."

1879. The Edison Telephone Company of London was formed. Both the Bell and the Edison Companies opened negotiations with the Post Office for the sale of their patents to the government, but without success. The Edison Company announced its intention to start telephone business in London, and the Postmaster-General instituted proceedings against the company for infringement of his monopoly rights under the Telegraph Act 1869.

1880. The two companies amalgamated as the United Telephone Company Ltd. Mr Justice Stephen decided (*Attorney-General* v. *Edison Telephone Company*, 6 Q.B.D., 244) that the telephone was a telegraph, and that telephone exchange business could not legally be carried on except by the Postmaster-General or with his consent. The decision covered also future invention in regard to "every organized system of communication by means of wires according to any preconcerted system of signals."

1881. The company's appeal against the decision was withdrawn, the Postmaster-General agreeing to grant licences for restricted areas of about 5 m. in London and about 2 m. in the provinces. The licences merely condoned the infringement of the Telegraph Act 1869, and did not confer powers to erect poles and wires on, or to place wires under, any highway or private property. The licensee was precluded from opening public call offices and from laying trunk lines from one town to another. The licences were for 31 years, expiring in 1922, without any provision for purchase or compensation, and were subject to the payment of a minimum royalty to the Post Office of 10 per cent. of the gross revenues. The United Telephone Company confined its operations to London; subsidiary companies were formed to operate in the provinces. The Post Office at the same time established several telephone exchanges in provincial towns so as to enable the Postmaster-General "to negotiate with the telephone companies in a satisfactory manner for licences."

1882. The Postmaster-General (Mr Fawcett) declared that he would issue no more licences unless the licensees agreed to sell telephones to the Post Office. As a result only eight companies out of over seventy that had applied obtained or accepted licences.

1883. The Post Office proposed to engage in active competition with the telephone companies, but the Treasury at that time opposed this policy on the ground that the state should at most be ready to supplement and not to supersede private enterprise.

1884. The licences within restricted areas having proved unsuitable for the growing business, public opinion appealed to the Post Office to issue new licences applicable to the whole country. All limitations of areas were removed and licensees were allowed to open public call offices but not to receive or deliver written messages, and they were allowed to erect trunk wires. The royalty of 10 per cent. was continued. The Post Office reserved the right to compete either directly or by granting other licences, and it was under no obligation to grant wayleaves. The new licences were to terminate in 1911 without any provision for purchase or compensation in that year, but with the option to the government to purchase the plant of the licensees in 1890, 1897, or 1904 at a price to be determined by arbitration. The United Telephone Company asked parliament for rights of way in streets but was refused, and its only right to place overhead wires was obtained by private wayleaves.

1885. The United Telephone Company again applied unsuccessfully for right to lay wires underground.

1888. The application of the company for permission to lay wires in streets was again refused.

1889. After the withdrawal of the restriction against the companies erecting trunk wires it became evident that the development of the telephone services throughout the country would be facilitated by complete intercommunication and uniformity of systems, and that economies could be effected by concentration of management. The various companies therefore amalgamated as the National Telephone Company.

1890. The government had the option to buy out the companies under the licences of 1884, but did not exercise it. The Bell telephone patents expired. The National Telephone Company applied to the London County Council for permission to lay wires underground and continued efforts till 1899 to obtain this power, but without success.

1891. The duke of Marlborough, in the name of the New Telephone Company, inaugurated a campaign for cheaper telephone services, but the New Telephone Company was subsequently merged in the National Telephone Company.

1892. The National Telephone Company again applied to parliament for powers to lay wires underground; public discontent with inadequate telephone services was expressed, and at the same time the competition of the telephone with the Post Office telegraph became more manifest. The government again changed its policy. It compelled the companies to sell their trunk wires to the Post Office, leaving the local exchanges in the hands of the companies. It also expressed willingness that the companies should have rights of way in the streets.

1893. The National Telephone Company again applied to parliament for power to lay wires underground, but was refused.

1894. The draft agreement between the government and the National Telephone Company to carry out the policy of 1892 was submitted to parliament and led to much discussion. Local authorities (particularly London and Glasgow) refused to permit the company to lay wires underground.

1895. A select committee of the House of Commons (with Mr Arnold Morley, Postmaster-General, as chairman) was appointed "to consider and report whether the provision now made for the telephone service in local areas is adequate, and whether it is expedient to supplement or improve this provision either by the granting of licences to local authorities or otherwise." The committee was not unanimous and made no report, but merely submitted to the House the evidence it had taken.

1896. The trunk wires were transferred to the Post Office in pursuance of the policy of 1892, but for all practical purposes the local authorities had vetoed the permission of the government to the company to lay wires underground.

1897. The government had an option to purchase the plant of the company under the licences of 1884, but did not exercise it. The corporation of Glasgow having persisted in its efforts to obtain a licence, the Treasury appointed Sheriff Andrew Jameson (afterwards Lord Ardwall) a special commissioner to hold a local inquiry in Glasgow to report whether the telephone service in that city was adequate and efficient and whether it was expedient to grant the corporation a licence. The commissioner reported that the service was adequate but not efficient; that the rates were reasonable but that the corporation was responsible for unreasonably withholding facilities, thus rendering the service inefficient; that it was inexpedient to grant the corporation a licence because the funds of a city ought not to be applied for the benefit of a limited class of citizens; that delay and waste would result from two systems in one area and would increase the difficulties of the government in 1911; and that the corporation had not proved it could work the licence without placing a burden on the rates.

1898. The policy of the government was again changed; Mr R. W. Hanbury, Financial Secretary to the Treasury and representative in the House of Commons of the Postmaster-General, advocated the granting of licences to local authorities. A select committee was appointed with Mr Hanbury as chairman to consider "whether the telephone service is calculated to become of such general benefit as to justify its being undertaken by municipal and other local authorities, and if so under what conditions." The committee reported (9th August) that the telephone service was not likely to become of general benefit "so long as the present practical monopoly in the hands of a private company shall continue." The committee considered that the Post Office was not prevented either by legal agreement or by good faith from limiting or ending the monopoly of the company, and that competition appeared to be both expedient and necessary in order to extend and popularize the service and to avoid the danger that a purchase of the company's undertaking at an inflated price might be forced upon the government. While considering that a really efficient Post Office service would afford the best means for securing such competition, it recommended that general, immediate and effective competition should at once be undertaken either by the Post Office or by local authorities. The Association of Municipal Corporations passed resolutions on the 28th of April that "the subject of telephonic supply should be treated as an imperial and not as a local one, and that the Postmaster-General should have the sole control of the telephone system," and "that in the event of the Postmaster-General not taking over the telephone service it should be competent for municipal and other local authorities to undertake such services within areas composed of their own districts or combination of such districts."

1899. In pursuance of the report of the select committee, 1898, the Telegraph Act 1899 was passed to enable the Post Office to develop its telephone exchange business, for which a loan of £2,000,000 was sanctioned, and to empower local authorities, subject to certain conditions, to enter upon telephone business. The licence of the National Telephone Company was extended so as to be co-extensive with that of a competitive licence for any locality on condition that the company should afford intercommunication with the telephone systems of the new licensees. In short, all-round competition was authorized, and the Post Office decided to establish a telephone system in London in competition with the company.

1900. The Telegraph Act 1899, while providing for intercommunication between the telephone systems of the local authorities and the company, did not give the Post Office the right to demand intercommunication between its exchanges and those of the company. The Post Office co-operated with the London County Council to put difficulties in the way of the company which had placed wires underground in London with the consent of the local road authorities. In February the Postmaster-General applied for an injunction to restrain the company from opening any street or public road within the county of London without the consent of the Postmaster-General and the London County Council, which injunction was granted in July.

1901. The government policy of 1899 was abandoned in London, the Post Office making an agreement with the company in regard to the London business. The company consented to free intercommunication between its subscribers and those of the Post Office, and undertook to charge rates identical with those charged by the Post Office. The Postmaster-General on the other hand agreed to provide underground wires for the company on a rental, and agreed to buy in 1911 the company's plant in London at the cost of construction less allowance for repairs and depreciation.

1904. The government had option to purchase the company's provincial plant under the licence of 1884. Negotiations took place, but no agreement was reached.

1905. The government contracted to buy the company's plant in 1911, thus in effect annulling the act of 1899 which had failed to accomplish its object of establishing all-round competition.

By 1907 altogether 59 local authorities had examined the proposition of establishing telephone systems after 1899, and licences were granted to local authorities at Brighton, Belfast, Chard, Glasgow, Grantham, Huddersfield, Hull, Portsmouth, Swansea, Tunbridge Wells, Oldham, Scarborough and Hartlepool, but only six municipalities proceeded with the business. Glasgow opened its exchange in March 1901, Tunbridge Wells in May 1901, Portsmouth in March 1903, Brighton in October 1903, Swansea in November 1903 and Hull in October 1904. The Tunbridge Wells and Swansea municipal undertakings were subsequently sold to the National Telephone Company, and the Glasgow and Brighton undertakings to the Post Office. Hull and Portsmouth were the only municipal telephone systems working in 1907.

The effect of the unsettled policy of the Post Office until 1905 and of the difficulties created by the local authorities was that the National Telephone Company was never able to do its best to develop the enterprise on the most efficient lines. In 1885 there were only 3800 telephone subscribers in London and less than 10,000 in the rest of the United Kingdom, and telephonic services were available in only about 75 towns, while in the same year the American Bell Telephone Company had over 134,000 subscribers. The removal in 1884 of the prohibition against the erection of trunk lines at once enabled considerable expansion to take place. Within six years the services had been extended to 400 towns with about 55,000 subscribers. Large as this progress was it would have been much greater if the Telephone Company had been granted adequate powers to put wires underground and thus instal a complete metallic circuit in place of the single wire, earth-return, circuit which it was constrained to employ. Subsequently the progress was still greater. In 1906 there were 30,551, equal to 7·2 per cent., more telephone stations in the United Kingdom than in the ten European countries of Austria, Hungary, Belgium, Denmark, Holland, Italy, Norway, Portugal, Russia, Sweden and Switzerland, having a combined population of 288 millions as against a population of 42 millions in the United Kingdom. Apart from France, Germany and Switzerland, there was no European country that had as many telephones working as London. That city, with a population of 6 millions, had nearly as many telephones as the whole of Sweden with about the same population, or as the whole of France, with a population of 39 millions. The only European country which can be compared with the United Kingdom in telephone development is Germany. With a population of 58 millions there are 10·2 telephones per 1000 of the population in that country compared with 10·15 in Great Britain and Ireland. The development of telephony in the United States of America is much greater than anywhere else; on the 1st of January 1907, 5 per cent. of the population were telephone subscribers.

Tariffs.—Telephone business is characterized by two features: (1) that the capital account is never closed, and (2) that the costliness of the service increases with the size of the undertaking. The original method of charging adopted in Great Britain took the telephone instrument as the unit, charging a fixed annual rental independent of the amount of use to which the instrument was put. The study of telephone economics showed that the proper basis for charging was the "message-mile," on the theory that the user should pay according to the facilities offered and the extent to which he made use of them. In a large city, where several interconnected exchanges have to be built and thousands of subscribers are put into communication with each other, the service is at once more costly and more valuable than in a small town with a few hundred subscribers accommodated in one exchange. Differences not only in the size of towns, but in the arrangement and character of the population, make each district a telephone problem by itself, and nullify close comparisons between telephone rates and telephone efficiencies in different areas and different countries. But the tendency is towards a system of charging a moderate sum to cover the rent of the instrument and an additional fee per message. For instance, in the county of London, the telephone tariff is £5 per annum plus 1d. per call within the county and 2d. per call outside the county. Subscribers outside the county of London pay only £4 in annual subscription and 1d. per call to subscribers on the same exchange and 2d. per call to subscribers on other exchanges. In each case the minimum annual amount for message fees is £1, 10s. The alternative is given of an unlimited service ("flat rate") at £17 per annum. In the provinces the unlimited service costs only £7, 10s. for subscribers within half a mile of the exchange, £1, 5s. being charged for every additional quarter of a mile or fraction thereof. The toll or message rates are £3, with 1d. per call, with a minimum of £1, 10s. As the cost of the service varies in proportion to the amount of use, the toll rate is more scientific, and it has the further advantage of discouraging the unnecessary use of the instrument, which causes congestion of traffic at busy hours and also results in lines being "engaged" when serious business calls are made. The tariff for unlimited use has to be made very high to cover the cost of the additional burdens thrown upon the service, and it only works economically to the individual subscriber who has an exceptionally large number of calls originating from his instrument. The message-rate system equalizes the charges according to the service rendered. Another method of charge, known as the "measured service rate," is designed to make the subscriber pay in proportion to the quality and quantity of the service he takes. It is widely used in America, and was introduced into Great Britain in 1907. The subscriber pays a fixed annual rent which covers a certain number of free outward calls, say 500; additional calls he purchases in advance in blocks of several hundred at so much per hundred, the price being reduced as the number increases.

For subscribers who desire the telephone for occasional use, the party-line system has been devised, whereby several telephones are connected to one line leading to the exchange. In London a two-line party service costs £3 per annum, the message fees being 1d. per call to subscribers within the county and 2d. per call to those outside it, with a minimum of £3. The fee charged for the use of public telephone call offices is 2d. per message.

The trunk line service is charged for on rates which vary from 3d. (for 25 m.) up to 1s. (for 100 m.) for a three minutes' conversation between 6 a.m. and 8 p.m. For every 40 m. above 100 m. an additional 6d. per conversation is charged. A reduction has been made in the charges for trunk calls at night, and calls for single periods of three minutes are allowed at half the ordinary rates between 7 p.m. and 7 a.m. A call between London and Liverpool, which ordinarily costs 2s., can be made for 1s. between those hours. The growth of traffic on this basis has been considerable, and the arrangement has proved of advantage to the public, as it provides cheap facilities at times which are convenient for social conversation.

Telephone subscribers may telephone ordinary messages to any post office which may be reached through the local exchange system, or by means of the trunk wires, in order that the messages may be written down and forwarded as telegrams or express letters or ordinary letters. Subscribers to exchanges may also make arrangements to have all telegrams (except Press telegrams) addressed to them delivered by telephone instead of messenger. Telephone subscribers may also obtain the services of an express messenger by telephoning to the nearest post office connected with the exchange.

National Telephone Company.—The issued share and debenture capital of the company on the 31st of December 1907 was:—

15,000 6% 1st preference shares of £10 each	£150,000
15,000 6% 2nd preference shares of £10 each	150,000
250,000 5% 3rd preference shares of £5 each	1,250,000
6% preferred stock	2,225,000
Deferred stock	3,366,425
71,715 new shares of £5 each	358,575
	£7,500,000
3½% debenture stock	2,000,000
4% debenture stock	1,716,593
	£11,216,593

The company has a reserve fund of £2,467,707, the major part of which is invested in the business. The gross income for the year 1907 amounted to £2,702,228, of which £257,920 was paid to the Post Office in respect of royalties. The working expenses amounted to £1,530,093 or 62·6 per cent. of the net income, leaving a profit for the year of £914,216.

At the time of the formation of the various telephone companies the enterprises were regarded as speculative, and much of the capital was raised at a discount. The business subsequently proved profitable, good dividends were paid, and the securities for the most part commanded a premium in the market. After the consolidation of the companies in 1889–1890 the profits declined, patent rights had expired, material reductions were made in the rates for telephone services, and considerable replacements of plant became necessary, the cost of which was charged to revenue.

Agreement of 1905.—By this agreement the Postmaster-General agreed to purchase all plant, land and buildings of the National Telephone Company in use at the date of the agreement or constructed after that date in accordance with the specification and rules contained in the agreement, subject to the right of the Postmaster-General to object to take over any plant not suited to his requirements. The price is to be fixed by the Railway and Canal Commissioners as arbitrators on the basis of the "then value," exclusive of any allowance for past or future profits or any compensation for compulsory sale or other consideration. In those cases in which the company's licence has been extended beyond 1911 (Glasgow to 1913, Swansea to 1926, Brighton to 1926 and Portsmouth to 1926) the Postmaster-General will buy the unexpired licence with allowance for goodwill. The Postmaster-General agreed also to buy the private wire plant of the company at a value based upon three years' purchase of the net profits on the average of the three years ending 31st of December 1911. The Postmaster-General also agreed to lay underground wires for the company at an annual rental of £1 per mile of double wire in any local area in which the company was operating, but not in areas in which the municipalities had established exchanges. Free intercommunication was established by the agreement between the subscribers of the company and those of the Post Office, and a scale of charges was adopted or arranged to be agreed as binding on both the Post Office and the company. The late Mr W. E. L. Gaine, general manager of the company, stated before the Select Committee that in the view of the directors the bargain was a hard one, because it gave no consideration in respect of the goodwill of the great business, with its gross income of over £2,000,000 per annum and its net revenue of over £750,000, which the company had built up. The company had had to pay for all the experiments and mistakes which are inherent in the launching and development of any new industry. It had paid the Post Office in royalties already £1,848,000, and the Post Office under the agreement would step into the business in 1911 by merely paying for the plant employed. The Association of Municipal Corporations and the London County Council, on the other hand, considered the terms of purchase to be too favourable to the company. The London County Council, according to the statement of its comptroller, was disturbed by the hope expressed by the manager of the company, that the holders of the company's ordinary shares would obtain the par value of their shares in 1911. Inasmuch as the debenture stocks and preference shares would have to be redeemed in 1911 at premiums ranging from 3 to 5 per cent., the state would have to pay the company £253,000 in excess of the total of the outstanding securities in order to enable the ordinary shares to receive par, and in the council's view this payment would diminish the probability of the Post Office being able to afford a substantial reduction in the telephone charges.

Post Office Telephones.—The number of trunk wire centres open on the 31st of March 1907 was 533, and the total number of trunk circuits was 2043, containing about 73,000 m. of double wire. The capital expenditure on the purchase and development of the trunk wire system amounted to £3,376,252. The total number of conversations which took place over the trunk wires during the year 1906–1907 was 19,803,300. The gross revenue derived from the trunk services was £480,658, being an average of 5·82d. per conversation. The total number of subscribers to the Post Office provincial exchanges on the 31st of March 1907 (excluding those in Glasgow and Brighton) was 10,010, and the number of telephones rented was 12,006. The Glasgow system included 11,103 subscribers' lines with 12,964 telephones, and the Brighton system contained 1542 subscribers' lines with 1884 telephones. The sum received by the Post Office as rental in respect of private wires was £183,000. The years' working of the whole telephone system of the Post Office showed a balance of £451,787 after payment of the working expenses, while the estimated amount required to provide for depreciation of plant and interest at 3 per cent. on the total expenditure of £7,252,000 was £432,726.

The number of telephones connected with the Post Office system in the metropolitan area on the 31st of March 1907 was 41,236, and additional subscribers were being connected at the rate of about 150 a week. There were 425 post office call-offices in the London area. The length of underground pipes which had been laid in the metropolitan area for telephone purposes was 2030 m. Cables containing 317,789 m. of wire had been laid, including 69,066 m. rented by the National Telephone Company. The average cost of constructing an exchange circuit in the metropolitan area (including the installation of telephone instruments and of exchange apparatus, but excluding the provision of spare plant) has been £33. Taking into account the whole system (including spare plant of all kinds), the capital expenditure per station (*i.e.* per telephone connected with an exchange) stands at less than £50.

International Telephone Lines.—The Anglo-French telephone service, which was opened between London and Paris in April 1891, was extended to the principal towns in England and France on the 11th of April 1904. The service has since been extended to certain other English provincial towns; and the Anglo-Belgian telephone service has similarly been extended. There are now four circuits between London and Paris, one between London and Lille, and two between London and Brussels, the last carrying an increasing amount of traffic. Experiments have been made in telephonic communication between London and Rome by way of Paris. It was found possible to exchange speech when the conditions were exceptionally favourable; but in spite of the partial success of the experiment, a public service between the two capitals is not at present practicable.

TELESCOPE, an optical instrument employed to view distant objects. The term "photographic telescope" has been applied to instruments employed to record the appearance of celestial objects by photography. The word was coined by Demiscianus, a Greek scholar, at the request of Federigo Cesi, founder of the *Accademia dei Lincei*, from the Greek τῆλε, far, and σκοπευν, to see. It was used by Galileo as early as 1612, and came into English use much later, when it supplanted *trunk* and *cylinder*, the terms hitherto used to denote the telescope.

History

The credit of the discovery of the telescope has been a fruitful subject of discussion. Thus, because Democritus announced that the Milky Way is composed of vast multitudes of stars, it has been maintained that he could only have been led to form such an opinion from actual examination of the heavens with a telescope. Other passages from the Greek and Latin authors have similarly been cited to prove that the telescope was known to the ancients. But, as has been remarked by Dr Robert Grant (*History of Physical Astronomy*, p. 515), we are no more warranted in drawing so important a conclusion from casual remarks, however sagacious, than we should be justified in stating that Seneca was in possession of the discoveries of Newton because he predicted that comets would one day be found to revolve in periodic orbits. William Molyneux, in his *Dioptrica Nova* (1692), p. 256, declares his opinion that Roger Bacon (who died *c.* 1294) "did perfectly well understand all kinds of optic glasses, and knew likewise the method of combining them so as to compose some such instrument as our telescope." He cites a passage from Bacon's *Opus Majus*, p. 377 of Jebb's edition, 1733, translated as follows:—

"Greater things than these may be performed by refracted vision. For it is easy to understand by the canons above mentioned that the greatest objects may appear exceedingly small, and the contrary, also that the most remote objects may appear just at hand, and the converse; for we can give such figures to transparent bodies, and dispose them in such order with respect to the eye and the objects, that the rays shall be refracted and bent towards any place we please, so that we shall see the object near at hand or at any distance under any angle we please. And thus from an incredible distance we may read the smallest letters, and may number the smallest particles of dust and sand, by reason of the greatness of the angle under which we see them. . . . Thus also the sun, moon and stars may be made to descend hither in appearance, and to be visible over the heads of our enemies, and many things of the like sort, which persons unacquainted with such things would refuse to believe."

Molyneux also cites from Bacon's *Epistola ad Parisiensem*, "Of the Secrets of Art and Nature," chap. 5:—

"Glasses or diaphanous bodies may be so formed that the most remote objects may appear just at hand, and the contrary, so that we may read the smallest letters at an incredible distance, and may number things, though never so small, and may make the stars also appear as near as we please."

These passages certainly prove that Bacon had very nearly, if not perfectly, arrived at theoretical proof of the possibility of constructing a telescope and a microscope; but his writings give no account of the trial of an actual telescope, nor any detailed results of the application of a telescope to an examination of the heavens. It has been pointed out by Dr Robert Smith, in his *Complete System of Opticks*, that Bacon imagines some effects of telescopes which cannot be performed by them, and his conclusion is that Bacon never actually looked through a telescope.

Giambattista della Porta, in his *Magia Naturalis*, printed in 1558, makes the following remarkable statement:—

"If you do but know how to join the two (viz., the concave and the convex glasses) rightly together, you will see both remote and near objects larger than they otherwise appear, and withal very distinct."

Wolfius infers from this passage that its author was the first actual constructor of a telescope, and it appears not improbable that by happy accident Porta really did make some primitive form of telescope which excited the wonder of his friends. Here, however, his interest in the matter appears to have ceased, and he was unable either to appreciate the importance of his discovery or to describe the means by which the object was attained. Kepler, who examined Porta's account of his concave and convex lenses by desire of his patron the emperor Rudolph, declared that it was perfectly unintelligible. Poggendorff (*Gesch. der Physik*, p. 134) throws considerable doubt on the originality of Porta's statement.

Thomas Digges, in his *Stratiolicus*, p. 359, published in 1579, states that his father, Leonard Digges,

"among other curious practices had a method of discovering by perspective glasses set at due angles all objects pretty far distant that the sun shone upon, which lay in the country round about,"

and that this was by the help of a manuscript book of Roger Bacon of Oxford, who he conceived was the only man besides his father who knew it. There is also the following passage in the *Pantometria* (bk. i. chap. 21) of Leonard Digges [1] (originally published by his son Thomas in 1571, and again in 1591):—

"Marvellous are the conclusions that may be performed by glasses concave and convex, of circular and parabolic forms, using for multiplication of beams sometime the aid of glasses transparent, which, by fraction, should unite or dissipate the images or figures presented by the reflection of other."

He then describes the effects of magnification from a combination of lenses or mirrors, adding:—

"But of these conclusions I minde not here to intreate, having at large in a volume [2] by itselfe opened the miraculous effects of perspective glasses."

It is impossible to discredit the significance of these quotations, for the works in which they occur were published more than twenty years before the original date claimed for the discovery of the telescope in Holland.

But it is quite certain that previous to 1600 the telescope was unknown, except possibly to individuals who failed to see its practical importance, and who confined its use to "curious practices" or to demonstrations of "natural magic." The practical discovery of the instrument was certainly made in Holland about 1608, but the credit of the original invention has been claimed on behalf of three individuals, Hans Lippershey and Zacharias Jansen, spectacle-makers in Middelburg, and James Metius of Alkmaar (brother of Adrian Metius the mathematician).

Descartes, in his treatise on *Dioptrics* (1637), attributes the discovery to Metius "about thirty years ago," whilst Schyraelus de Rheita, a Capuchin friar, in his *Oculus Enoch et Eliae* (Antwerp, 1645), gives the credit to Lippershey about 1609. Peter Borel, physician to the king of France, published at The Hague, in 1655, a work *De Vero Telescopii Inventore*. He was assisted in its preparation by William Borel, Dutch envoy at the court of France, and the latter declares, as the result of patient investigation, that Jansen and his father were the real inventors of the telescope in 1610, and that Lippershey only made a telescope after hints accidentally communicated to him of the details of Jansen's invention. But the most trustworthy information on the subject is to be got from the researches of J. H. van Swinden.[3] Briefly summarized, this evidence is as follows. In the library of the university of Leyden, amongst the MSS. of Huygens there is an original copy of a document (dated 17th October 1608) addressed to the states-general by Jacob Andrianzoon (the same individual who is called James Metius by Descartes), petitioning for the exclusive right of selling an instrument of his invention by which distant objects appear larger and more distinct. He states that he had discovered the instrument by accident when engaged in making experiments, and had so far perfected it that distant objects were made as visible and distinct by his instrument as could be done with the one which had been lately offered to the states by a citizen and spectacle-maker of Middelburg. Among the acts of the states-general preserved in the government archives at The Hague, Van Swinden found that on 2nd October 1608 the assembly of the states took into consideration the petition of Hans Lippershey, spectacle-maker, a native of Wesel and an inhabitant of Middelburg, inventor of an instrument for seeing at a distance. On 4th October a committee was appointed to test the instrument, and on the 6th of the same month the assembly agreed to give Lippershey 900 florins for his instrument. Further, on the 15th December of the same year they examined an instrument invented by Lippershey at their request to see with both eyes, and gave him orders to execute two similar instruments at 900 florins each; but, as many other persons had knowledge of this new invention to see at a distance, they did not deem it expedient to grant him an exclusive privilege to sell such instruments. The dates of these documents dispose effectually of Borel's statement that Lippershey borrowed the ideas of Jansen in 1610. They also prove that, whilst Metius was in possession of a telescope, with which he may have experimented, about the time when Lippershey presented his application for patent rights, yet he makes no pretension that Lippershey borrowed the invention from him. The conclusion is that Lippershey was the first person who independently invented the telescope, and at the same time made the instrument known to the world. The common story is that Lippershey, happening one day, whilst holding a spectacle-lens in either hand, to direct them towards the steeple of a neighbouring church, was astonished, on looking through the nearer lens, to find that the weathercock appeared nearer and more distinct. He fitted the lenses in a tube, in order to adjust and preserve their relative distances, and thus constructed his first telescope. But doubt may be thrown on this traditional account owing to the further statement that the image of the weathercock so viewed was seen turned upside down. All the original Dutch telescopes were composed of a convex and a concave lens, and telescopes so constructed do not invert. The inverting telescope, composed of two convex lenses, was a later invention; still it is not impossible that the original experiment was made with two convex lenses.

Telescopes seem to have been made in Holland in considerable numbers soon after the date of their invention, and rapidly found their way over Europe. Sirturus, in his *De Telescopio* (1618), states that "a Frenchman proceeded to Milan in the month of May 1609 and offered a telescope for sale to Count di Fuentes"; and Lorenzi Pigorna writes,[4] under date 31st August 1609, that "Galileo had been appointed lecturer at Padua for life on account of a perspective like the one which was sent from Flanders to Cardinal Borghese." Simon Marius, the German astronomer, appears to have made astronomical observations in 1609 with a telescope which he procured from Holland, and Professor S. P. Rigaud of Oxford found from the MSS. of Harriot, the mathematician, that he had been making astronomical observations with a Dutch telescope as early as July 1609. Galileo, in his *Nuncius Sidereus*, states that, happening to be in Venice about the month of May 1609, he heard that a Belgian had invented a perspective instrument by means of which distant objects appeared nearer and larger, and that he discovered its construction by considering the effects of refraction. In his *Saggiatore* Galileo states that he solved the problem of the construction of a telescope the first night after his return to Padua from Venice, and made his first telescope next day by fitting a convex lens in one extremity of a leaden tube and a concave lens in the other one. A few days afterwards, having succeeded in making a better telescope than

[1] He died about 1570. His son alludes to his untimely death in the preface to the *Pantometria*.

[2] There is no further trace of this volume.

[3] See Dr G. Moll of Utrecht, in *Journ. Roy. Inst.*, vol. i., 1831.

[4] *Lettre d' Uomini Illustri*, p. 112 (Venice, 1744).

the first, he took it to Venice, where he communicated the details of his invention to the public, and presented the instrument itself to the doge Leonardo Donato, sitting in full council. The senate, in return, settled him for life in his lectureship at Padua and doubled his salary, which was previously 500 florins and which then became treble that which any of his predecessors had enjoyed. Galileo may thus claim to have invented the telescope independently, but not till he had heard that others had done so. In fact the time was ripe; and, as often happens in similar circumstances, only a hint was necessary to complete the latent chain of thought. Galileo devoted all his time to improving and perfecting the telescope. Knowing the theory of his instrument, and possessed of much practical skill, coupled with unwearied patience, he conquered the difficulties of grinding and polishing the lenses, and soon succeeded in producing telescopes of greatly increased power. His first telescope magnified three diameters; but he soon made instruments which magnified eight diameters, and finally one that magnified thirty-three diameters.[1] With this last instrument he discovered in 1610 the satellites of Jupiter, and soon afterwards the spots on the sun, the phases of Venus, and the hills and valleys on the moon. He demonstrated the rotation of the satellites of Jupiter round the planet, and gave rough predictions of their configurations, proved the rotation of the sun on its axis, established the general truth of the Copernican system as compared with that of Ptolemy, and fairly routed the fanciful dogmas of the philosophers. These brilliant achievements, together with the immense improvement of the instrument under the hands of Galileo, overshadowed in a great degree the credit due to the original discoverer, and led to the universal adoption of the name of the Galilean telescope for the form of the instrument invented by Lippershey.

Kepler first explained the theory and some of the practical advantages of a telescope constructed of two convex lenses in his *Catoptrics* (1611). The first person who actually constructed a telescope of this form was the Jesuit Christoph Scheiner, who gives a description of it in his *Rosa Ursina* (1630). William Gascoigne was the first who practically appreciated the chief advantages of the form of telescope suggested by Kepler, viz., the visibility of the image of a distant object simultaneously with that of a small material object placed in the common focus of the two lenses. This led to his invention of the micrometer and his application of telescopic sights to astronomical instruments of precision (see MICROMETER). But it was not till about the middle of the 17th century that Kepler's telescope came into general use, and then, not so much because of the advantages pointed out by Gascoigne, but because its field of view was much larger than in the Galilean telescope. The first powerful telescopes of this construction were made by Huygens, after much labour, in which he was assisted by his brother. With one of these, of 12-ft. focal length, he discovered the brightest of Saturn's satellites (Titan) in 1655, and in 1659 he published his *Systema Saturnium*, in which was given for the first time a true explanation of Saturn's ring, founded on observations made with the same instrument. The sharpness of image in Kepler's telescope is very inferior to that of the Galilean instrument, so that when a high magnifying power is required it becomes essential to increase the focal length. G. D. Cassini discovered Saturn's fifth satellite (Rhea) in 1672 with a telescope of 35 ft., and the third and fourth satellites in 1684 with telescopes made by Campani of 100- and 136-ft. focal length. Huygens states that he and his brother made object-glasses of 170 and 210 ft. focal length, and he presented one of 123 ft. to the Royal Society of London. Adrien Auzout (d. 1691) and others are said to have made telescopes of from 300 to 600 ft. focus, but it does not appear that they were ever able to use them in practical observations. James Bradley, on 27th December 1722, actually measured the diameter of Venus with a telescope whose object-glass had a focal length of 212¼ ft. In these very long telescopes no tube was employed, and they were consequently termed *aerial telescopes*. Huygens contrived some ingenious arrangements for directing such telescopes towards any object visible in the heavens—the focal adjustment and centring of the eye-piece being preserved by a braced rod connecting the object-glass and eye-piece. Other contrivances for the same purpose are described by Philippe de la Hire (*Mém. de l'Acad.*, 1715) and by Nicolaus Hartsoeker (*Miscel. Berol.*, 1710, vol. i. p. 261). Telescopes of such great length were naturally difficult to use, and must have taxed to the utmost the skill and patience of the observers. One cannot but pay a passing tribute of admiration to the men who, with such troublesome tools, achieved such results.

Reflecting Telescopes.—Until Newton's discovery of the different refrangibility of light of different colours, it was generally supposed that object-glasses of telescopes were subject to no other errors than those which arose from the spherical figure of their surfaces, and the efforts of opticians were chiefly directed to the construction of lenses of other forms of curvature. James Gregory, in his *Optica Promota* (1663), discusses the forms of images and objects produced by lenses and mirrors, and shows that when the surfaces of the lenses or mirrors are portions of spheres the images are curves concave towards the objective, but if the curves of the surfaces are conic sections the spherical aberration is corrected. He was well aware of the failures of all attempts to perfect telescopes by employing lenses of various forms of curvature, and accordingly proposed the form of reflecting telescope which bears his name. But Gregory, according to his own confession, had no practical skill; he could find no optician capable of realizing his ideas, and after some fruitless attempts was obliged to abandon all hope of bringing his telescope into practical use. Newton was the first to construct a reflecting telescope. When in 1666 he made his discovery of the different refrangibility of light of different colours, he soon perceived that the faults of the refracting telescope were due much more to this cause than to the spherical figure of the lenses. He over-hastily concluded from some rough experiments (*Optics*, bk. i. pt. ii. prop. 3) "that all refracting substances diverged the prismatic colours in a constant proportion to their mean refraction"; and he drew the natural conclusion "that refraction could not be produced without colour," and therefore "that no improvement could be expected from the refracting telescope" (*Treatise on Optics*, p. 112). But, having ascertained by experiment that for all colours of light the angle of incidence is equal to the angle of reflexion, he turned his attention to the construction of reflecting telescopes. After much experiment he selected an alloy of tin and copper as the most suitable material for his specula, and he devised means for grinding and polishing them. He did not attempt the formation of a parabolic figure on account of the probable mechanical difficulties, and he had besides satisfied himself that the chromatic and not the spherical aberration formed the chief faults of previous telescopes. Newton's first telescope so far realized his expectations that he could see with its aid the satellites of Jupiter and the horns of Venus. Encouraged by this success, he made a second telescope of 6½-in. focal length, with a magnifying power of 38 diameters, which he presented to the Royal Society of London in December 1671. A third form of reflecting telescope was devised in 1672 by Cassegrain (*Journal des Sçavans*, 1672). No further practical advance appears to have been made in the design or construction of the instrument till the year 1723, when John Hadley (best known as the inventor of the sextant) presented to the Royal Society a reflecting telescope of the Newtonian construction, with a metallic speculum of 6-in. aperture and 62⅝-in. focal length, having eye-pieces magnifying up to 230 diameters. The instrument was examined by Pound and Bradley, the former of whom reported upon it in *Phil. Trans.*, 1723, No. 378, p. 382. After remarking that Newton's telescope "had lain neglected these fifty years," they stated that Hadley had sufficiently shown "that this noble invention does not consist

[1] This last power could not be exceeded with advantage in this form of telescope till after the invention of the achromatic object-glass.

in bare theory." They compared its performance with that of the object-glass of 123-ft. focal length presented to the Royal Society by Huygens, and found that Hadley's reflector

"will bear such a charge as to make it magnify the object as many times as the latter with its due charge, and that it represents objects as distinct, though not altogether so clear and bright. . . . Notwithstanding this difference in the brightness of the objects, we were able with this reflecting telescope to see whatever we have hitherto discovered with the Huygenian, particularly the transits of Jupiter's satellites and their shadows over his disk, the black list in Saturn's ring, and the edge of his shadow cast on his ring. We have also seen with it several times the five satellites of Saturn, in viewing of which this telescope had the advantage of the Huygenian at the time when we compared them; for, being in summer, and the Huygenian telescope being managed without a tube, the twilight prevented us from seeing in this some of these small objects which at the same time we could discern with the reflecting telescope."

Bradley and Molyneux, having been instructed by Hadley in his methods of polishing specula, succeeded in producing some telescopes of considerable power, one of which had a focal length of 8 ft.; and, Molyneux having communicated these methods to Scarlet and Hearn, two London opticians, the manufacture of telescopes as a matter of business was commenced by them (Smith's *Opticks*, bk. iii. ch. 1). But it was reserved for James Short of Edinburgh to give practical effect to Gregory's original idea. Born at Edinburgh in 1710 and originally educated for the church, Short attracted the attention of Maclaurin, professor of mathematics at the university, who permitted him about 1732 to make use of his rooms in the college buildings for experiments in the construction of telescopes. In Short's first telescopes the specula were of glass, as suggested by Gregory, but he afterwards used metallic specula only, and succeeded in giving to them true parabolic and elliptic figures. Short then adopted telescope-making as his profession, which he practised first in Edinburgh and afterwards in London. All Short's telescopes were of the Gregorian form, and some of them retain even to the present day their original high polish and sharp definition. Short died in London in 1768, having realized a considerable fortune by the exercise of his profession.

Achromatic Telescope.—The historical sequence of events now brings us to the discovery of the achromatic telescope. The first person who succeeded in making achromatic refracting telescopes seems to have been Chester Moor Hall, a gentleman of Essex. He argued that the different humours of the human eye so refract rays of light as to produce an image on the retina which is free from colour, and he reasonably argued that it might be possible to produce a like result by combining lenses composed of different refracting media.[1] After devoting some time to the inquiry he found that by combining lenses formed of different kinds of glass the effect of the unequal refrangibility of light was corrected, and in 1733 he succeeded in constructing telescopes which exhibited objects free from colour. One of these instruments of only 20-in. focal length had an aperture of $2\frac{1}{2}$ in. Hall was a man of independent means, and seems to have been careless of fame; at least he took no trouble to communicate his invention to the world. At a trial in Westminster Hall about the patent rights granted to John Dollond (Watkin *v.* Dollond),[2] Hall was admitted to be the first inventor of the achromatic telescope; but it was ruled by Lord Mansfield that "it was not the person who locked his invention in his scrutoire that ought to profit for such invention, but he who brought it forth for the benefit of mankind."[3] In 1747 Leonhard Euler communicated to the Berlin Academy of Sciences a memoir in which he endeavoured to prove the possibility of correcting both the chromatic and the spherical aberration of an object-glass. Like Gregory and Hall, he argued that, since the various humours of the human eye were so combined as to produce a perfect image, it should be possible by suitable combinations of lenses of different refracting media to construct a perfect object-glass. Adopting a hypothetical law of the dispersion of differently coloured rays of light, he proved analytically the possibility of constructing an achromatic object-glass composed of lenses of glass and water. But all his efforts to produce an actual object-glass of this construction were fruitless—a failure which he attributed solely to the difficulty of procuring lenses worked precisely to the requisite curves (*Mem. Acad. Berlin*, 1753). Dollond admitted the accuracy of Euler's analysis, but disputed his hypothesis on the grounds that it was purely a theoretical assumption, that the theory was opposed to the results of Newton's experiments on the refrangibility of light, and that it was impossible to determine a physical law from analytical reasoning alone (*Phil. Trans.*, 1753, p. 289). In 1754 Euler communicated to the Berlin Academy a further memoir, in which, starting from the hypothesis that light consists of vibrations excited in an elastic fluid by luminous bodies, and that the difference of colour of light is due to the greater or less frequency of these vibrations in a given time, he deduced his previous results. He did not doubt the accuracy of Newton's experiments quoted by Dollond, because he asserted that the difference between the law deduced by Newton and that which he assumed would not be rendered sensible by such an experiment.[4] Dollond did not reply to this memoir, but soon afterwards he received an abstract of a memoir by Samuel Klingenstierna, the Swedish mathematician and astronomer, which led him to doubt the accuracy of the results deduced by Newton on the dispersion of refracted light. Klingenstierna showed from purely geometrical considerations, fully appreciated by Dollond, that the results of Newton's experiments could not be brought into harmony with other universally accepted facts of refraction. Like a practical man, Dollond at once put his doubts to the test of experiment, confirmed the conclusions of Klingenstierna, discovered "a difference far beyond his hopes in the refractive qualities of different kinds of glass with respect to their divergency of colours," and was thus rapidly led to the construction of object-glasses in which first the chromatic and afterwards the spherical aberration were corrected (*Phil. Trans.*, 1758, p. 733).

We have thus followed somewhat minutely the history of the gradual process by which Dollond arrived independently at his invention of the refracting telescope, because it has been asserted that he borrowed the idea from others. Montucla,

[1] The same argument was employed by Gregory more than fifty years previously, but had been followed by no practical result. The lens of the human eye is not achromatic.

[2] At a meeting of the Royal Astronomical Society held on 9th May 1886 a legal document, signed by Chester Moor Hall, was presented by R. B. Prosser of the Patent Office to the society. On the same occasion A. C. Ranyard made the following interesting statement respecting Hall:—

"Some years ago very little was known about Moor Hall. It was known that, about seven years after the patent for making achromatic object-glasses was granted to Dollond, his claim to the invention was disputed by other instrument-makers, amongst them by a Mr Champness, an instrument-maker of Cornhill, who began to infringe the patent, alleging that John Dollond was not the real inventor, and that such telescopes had been made twenty-five years before the granting of his patent by Mr Moor Hall. John Dollond, to whom the Copley medal of the Royal Society had been given for his invention, was the dead, and his son brought an action for infringing the patent against Champness. There is no report of the case, but the facts are referred to in the reports of subsequent cases. It appears that workmen who had been employed by Mr Moor Hall were examined, and proved that they had made achromatic object-glasses as early as 1733. Dollond's patent was not set aside, though the evidence with regard to the prior manufacture was accepted by Lord Mansfield, who tried the case, as having been satisfactorily proved . . . Mr Hall was a bencher of the Inner Temple, and was alive at the time of the action. He was a man of some property, and is spoken of on his tombstone as an excellent lawyer and mathematician. He was not a fellow of the Royal Society, but must certainly have known of the gift of the Copley medal to Dollond. It is very curious the conflicting evidence we have to reconcile, but I think the balance of evidence is in favour of there having been a prior invention of achromatic object-glasses before the date of Dollond's patent" (*Astron. Register*, May 1886; see also the *Observatory* for same date).

[3] *Gentleman's Magazine*, 1790, part ii. p. 890.

[4] For a good account of this controversy, see Dr H. Servus, *Geschichte des Fernrohrs*, p. 77 seq. (Berlin, 1886).

in his *Histoire des Mathématiques* (pp. 448–449), gives the following footnote, communicated to him by Lalande:—

"Ce fut Chestermonhall" (an obvious misprint for Chester Moor Hall) "qui, vers 1750, eut l'idée des lunettes achromatiques. Il s'adressoit à Ayscough[1] qui faisoit travaillir Bass. Dollond ayant eu besoin de Bass pour un verre que demandoit le duc d'Yorck, Bass lui fit voir du crown-glass et du flint-glass. Hall donna une lunette à Ayscough, qui la montra à plusieurs personnes; il en donna la construction à Bird, qui n'en tint pas compte. Dollond en profita. Dans le procès qu'il y eut entre Dollond et Watkin, au banc du roi, cela fut prouvé; mais Dollond gagna, parce qu'il étoit le premier qui eût fait connoître les lunettes achromatiques."

It is clearly established that Hall was the first inventor of the achromatic telescope; but Dollond did not borrow the invention from Hall without acknowledgment in the manner suggested by Lalande. His discovery was beyond question an independent one. The whole history of his researches proves how fully he was aware of the conditions necessary for the attainment of achromatism in refracting telescopes, and he may be well excused if he so long placed implicit reliance on the accuracy of experiments made by so illustrious a philosopher as Newton. His writings sufficiently show that but for this confidence he would have arrived sooner at a discovery for which his mind was fully prepared. It is, besides, impossible to read Dollond's memoir (*Phil. Trans.*, 1758, p. 733) without being impressed with the fact that it is a truthful account, not only of the successive steps by which he independently arrived at his discovery, but also of the logical processes by which these steps were successively suggested to his mind.

The triple object-glass, consisting of a combination of two convex lenses of crown glass with a concave flint lens between them, was introduced in 1765 by Peter, son of John Dollond, and many excellent telescopes of this kind were made by him.

The limits of this article do not permit a further detailed historical statement of the various steps by which the powers of the telescope were developed. Indeed, in its practical form the principle of the instrument has remained unchanged from the time of the Dollonds to the present day; and the history of its development may be summed up as consisting not in new optical discoveries but in utilizing new appliances for figuring and polishing, improved material for specula and lenses, more refined means of testing, and more perfect and convenient methods of mounting.

About the year 1774 William Herschel, then a teacher of music in Bath, began to occupy his leisure hours with the construction of specula, and finally devoted himself entirely to their construction and use. In 1778 he had selected the *chef-d'oeuvre* of some 400 specula which he made for the celebrated instrument of 7-ft. focal length with which his early brilliant astronomical discoveries were made. In 1783 he completed his reflector of $18\frac{7}{10}$ in. aperture and 20-ft. focus, and in 1789 his great reflector of 4-ft. aperture and 40-ft. focal length. The fame of these instruments was rapidly spread by the brilliant discoveries which their maker's genius and perseverance accomplished by their aid. The reflecting telescope became the only available tool of the astronomer when great light grasp was requisite, as the difficulty of procuring disks of glass (especially of flint glass) of suitable purity and homogeneity limited the dimensions of the achromatic telescope. It was in vain that the French Academy of Sciences offered prizes for perfect disks of optical flint glass. Some of the best chemists and most enterprising glass-manufacturers exerted their utmost efforts without succeeding in producing perfect disks of more than $3\frac{1}{2}$ in. in diameter. All the large disks were crossed by striae, or were otherwise deficient in the necessary homogeneity and purity. The subsequent history of the development of the art of manufacturing glass disks for telescopic objectives will be found in the article Glass: § *Optical*.

Instruments, &c.

We proceed to give an account of the methods and principles of construction of the various kinds of telescopes, and to describe in detail special typical instruments, which, owing to the work accomplished by their aid or the practical advances exemplified in their construction, appear most worthy of record or study.

[1] Ayscough was an optician in Ludgate Hill, London.

Refracting Telescope

In its simplest form the telescope consists of a convex objective capable of forming an image of a distant object and of an eye-lens, concave or convex, by which the image so formed is magnified. When the axis of the eye-lens coincides with that of the object-glass, and the focal point of the eye-lens is coincident with the principal focus of the object-lens, parallel rays incident upon the object-glass will emerge from the eye-piece as parallel rays. These, falling in turn on the lens of the human eye, are converged by it and form an image on the retina.

Fig. 1 shows the course of the rays when the eye-lens is convex (or positive), fig. 2 when the eye-lens is concave (or negative). The former represents Kepler's, the latter Lippershey's or the Galilean telescope. The magnifying power obviously depends on the proportion of the focal length of the object-lens to that of the eye-lens, that is,

$$\text{magnifying power} = F/e,$$

where F is the focal length of the object-lens and e that of the eye-lens. Also the diameter of the pencil or parallel rays emerging from the eye-lens is to the diameter of the object-lens inversely as the magnifying power of the telescope. Hence one of the best methods of determining the magnifying power of a telescope is to measure the diameter of the emergent pencil of rays, after the telescope has been adjusted to focus upon a star, and to divide the diameter of the object-glass by the diameter of the emergent pencil. If we desire to utilize all the parallel rays which fall upon an object-glass it is necessary that the full pencil of emerging rays should enter the observer's eye. Assuming with Sir William Herschel that the normal pupil of the eye distends to one-fifth of an inch in diameter when viewing faint objects, we obtain the rule that the minimum magnifying power which can be efficiently employed is five times the diameter of the object-glass expressed in inches.[2]

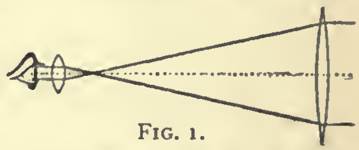

Fig. 1.

The defects of the Galilean and Kepler telescopes are due to the chromatic and spherical aberration of the simple lenses of which they are composed. The substitution of a positive or negative eye-piece for the simple convex or concave eye-lens, and of an achromatic object-glass for the simple object-lens, transforms these early forms into the modern achromatic telescope. The Galilean telescope with a concave eye-lens instead of an eye-piece still survives as the modern opera-glass, on account of its shorter length, but the object-glass and eye-lens are achromatic combinations.

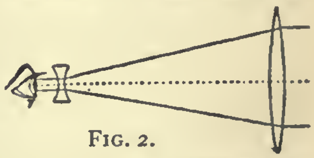

Fig. 2.

(D. Gi.)

Telescope Objectives.[3]—In spite of the improvements in the manufacture of optical glass (see Glass) practically the same crown and flint glasses as used by John Dollond in 1758 for achromatic objectives are still used for all the largest of the modern refracting telescopes.

It has long been known that the spectra of white or solar light yielded by ordinary crown and flint glasses are different: that while two prisms of such glasses may be arranged to give exactly the same angular dispersion between two Fraunhofer

[2] In the case of short-sighted persons the image for very distant objects (that is, for parallel rays) is formed in front of the retina; therefore, to enable such persons to see distinctly, the rays emerging from the eye-piece must be slightly divergent; that is, they must enter the eye as if they proceeded from a comparatively near object. For normal eyes the natural adaptation is not to focus for quite parallel rays, but on objects at a moderate distance, and practically, therefore, most persons do adjust the focus of a telescope, for most distinct and easy vision, so that the rays emerge from the eye-piece very slightly divergent. Abnormally short-sighted persons require to push in the eye-lens nearer to the object-glass, and long-sighted persons to withdraw it from the adjustment employed by those of normal sight. It is usual, however, in computations of the magnifying power of telescopes, for the rays emerging from the eye-piece when adjusted for distinct vision to be parallel.

[3] For the methods of grinding, polishing and testing lenses, see Objective.

lines, such as C and F, yet the flint glass prism will show a relative drawing out of the blue end and a crowding together of the red end of the spectrum, while the crown prism shows an opposite tendency. This want of proportion in the dispersion for different regions of the spectrum is called the "irrationality of dispersion"; and it is as a direct consequence of this irrationality, that there exists a secondary spectrum or residual colour dispersion, showing itself at the focus of all such telescopes, and roughly in proportion to their size. These glasses, however, still hold the field, although glasses are now produced whose irrationality of dispersion has been reduced to a very slight amount. The primary reason for this retention is that nothing approaching the difference in dispersive power between ordinary crown glass and ordinary dense flint glass (a difference of 1 to $1\frac{2}{3}$) has yet been obtained between any pair of the newer glasses. Consequently, for a certain focal length, much deeper curves must be resorted to if the new glasses are to be employed; this means not only greater difficulties in workmanship, but also greater thickness of glass, which militates against the chance of obtaining large disks quite free from striae and perfect in their state of annealing. In fact, superfine disks of over 15 in. aperture are scarcely possible in most of the newer telescope glasses. Moreover the greater depths of the curves (or "curvature powers") in itself neutralize more or less the advantages obtained from the reduced irrationality of dispersion. When all is taken into consideration it is scarcely possible to reduce the secondary colour aberration at the focus of such a double object-glass to less than a fourth part of that prevailing at the focus of a double objective of the same aperture and focus, but made of the ordinary crown and flint glasses.

The only way in which the secondary spectrum can be reduced still further is by the employment of *three* lenses of three different sorts of glass, by which arrangement the secondary spectrum has been reduced in the case of the Cooke photo visual objective to about 1/20th part of the usual amount, if the whole region of the visible spectrum is taken into account. It is possible to construct a triple objective of two positive lenses enclosing between them one negative lens, the two former being made of the same glass. For relatively short focal lengths a triple construction such as this is almost necessary in order to obtain an objective free from aberration of the 3rd order, and it might be thought at first that, given the closest attainable degree of rationality between the colour dispersions of the two glasses employed, which we will call crown and flint, it would be impossible to devise another form of triple objective, by retaining the same flint glass, but adopting two sorts of crown instead of only one, which would have its secondary spectrum very much further reduced. Yet such is the rather surprising fact. But it can be well illustrated in the case of the older glasses, as the following case will show.

The figures given are the partial dispersions for ordinary crown and ordinary extra dense flint glasses, styled in Messrs Schott's catalogue of optical glasses as 0·60 and 0·102 respectively, having refractive indices of 1·5179 and 1·6489 for the D ray respectively, and $(\mu_D-1)/(\mu_F-\mu_C)=60{\cdot}2$ and 33·8 respectively to indicate their dispersive powers (inverted), $=\nu$.

	C to F		A to D		D to F		F to G	
0·60	·00860	* 1·000	·00533	* ·643	·00605	* ·703	·00487	* ·566
0·102	·01919	1·000	·01152	·600	·01372	·714	·01180	·615
	·02779	1·000	·01685	·613	·01977	·711	·01667	·600

The $\Delta\mu$ from C to F being taken as unity in each case, then the $\Delta\mu$'s for the other regions of the spectrum are expressed in fractions $\Delta\mu$ (C to F) and are given under the asterisks. Let it be supposed that two positive lenses of equal curvature powers are made out of these two glasses, then in order to represent the combined dispersion of the two together the two $\Delta\mu$'s for each spectral region may be added together to form $\Delta'\mu$ as in the line below, and then, on again expressing the partial $\Delta'\mu$ in terms of $\Delta'\mu$ (C to F) we get the new figures in the bottom row beneath the asterisks. We find that we have now got a course of dispersion or degree of rationality which very closely corresponds to that of an ordinary light flint glass, styled 0·569 in Schott's catalogue, and having μ_D 1·5738 and $(\mu_D-1)/(\mu_F-\mu_C) = 41{\cdot}4 = \nu$, the figures of whose course of dispersion are as below:—

Light Flint Glass 0·569.

C to F		A′ to D		D to F		F to G	
·01385	1·000	·00583	·615	·00987	·713	·00831	·600

Hence it is clear that if the two positive lenses of equal curvature power of 0·60 and 0·102 respectively are combined with a negative lens of light flint 0·569, then a triple objective, having no secondary spectrum (at any rate with respect to the blue rays), may be obtained.

But while an achromatic combination of 0·60 and 0·102 alone will yield an objective whose focal length is only 1·28 times the focal length of the negative or extra dense flint lens, the triple combination will be found to yield an objective whose focal length is 73 times as great as the focal length of the negative light flint lens. Hence impossibly deep curvatures would be required for such a triple objective of any normal focal length. This case well illustrates the much closer approach to strict rationality of dispersion which is obtainable by using two different sorts of glass for the two positive lenses, even when one of them has a higher dispersive power than the glass used for the negative lens.

It is largely to this principle that the Cooke photo visual objective of three lenses (fig. 3) owes its high degree of achromatism. This form of objective has been successfully made up to $12\frac{1}{2}$ in. clear aperture. The front lens is made of baryta light flint glass

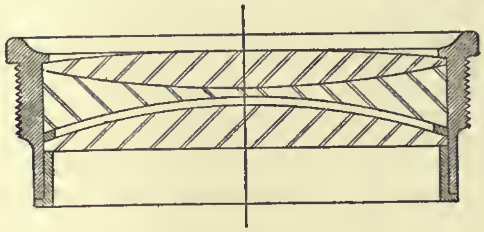

FIG. 3.

(0·543 of Schott's catalogue) and the back lens of a crown glass, styled 0·374 in Schott's older lists.

The table gives their partial dispersions for six different regions of the spectrum also expressed (in brackets below) as fractional parts of the dispersion from C to F.

	C to F	A to C	D to F	E to F	F to G′	F to H
0·543 $\mu_D =$ 1·564 ν = 50·7	·01115 (1·0000)	·00374 (·3354)	·00790 (·7085)	·00369 (·3309)	·00650 (·5830)	·01322 (1·1857)
0·374 $\mu_D =$ 1·511 ν = 60·8	·00844 (1·0000)	·00296 (·3507)	·00593 (·7026)	·00274 (·3247)	·00479 (·5675)	·00976 (1·1564)

Since the curvature powers of the positive lenses are equal, the partial dispersions of the two glasses may be simply added together, and we then have:—

[0·543+0·374]

C to F	A to C	D to F	E to F	F to G′	F to H
·01959 (1·0000)	·00670 (·3420)	·01383 (·7059)	·00643 (·3282)	·01129 (·5763)	·02298 (1·1730)

The proportions given on the lower line may now be compared with the corresponding proportional dispersions for borosilicate flint glass 0·658, closely resembling the type 0·164 of Schott's list, viz.:—

[0·658 ($\mu_D = 1{\cdot}546$) $\nu = 50{\cdot}1$]

C to F	A to C	D to F	E to F	F to G′	F to H
1·0000	·3425	·7052	·3278	·5767	1·1745

A slight increase in the relative power of the first lens of 0·543 would bring about a still closer correspondence in the rationality, but with the curves required to produce an object-glass of this type of 6 in. aperture and 108 in. focal length a discrepancy of 1 unit in the 3rd decimal place in the above proportional figures would cause a linear error in the focus for that colour of only about ·025 in., so that the largest deviation implied by the tables would be a focus for the extreme violet H ray about ·037 longer than the normal. It will be seen, then, that the visual and photographic foci are now merged in one, and the image is practically as achromatic as that yielded by a reflector.

Other types of triple object-glasses with reduced secondary spectra have recently been introduced. The extension of the image away from the axis or size of field available for covering a photographic plate with fair definition is a function in the first place of the ratio between focal length and aperture, the longer focus having the greater relative or angular covering power, and in the second a function of the curvatures of the lenses, in the sense that the objective must be free from coma at the foci of oblique pencils or must fulfil the sine condition (see ABERRATION).

Eye-pieces.—The eye-pieces or oculars through which, in case of visual observations, the primary images formed by the objective are viewed, are of quite secondary importance as regards definition in the central portion of the field of view. If an eye-piece blurs the definition in any degree in the centre of the field it must be very badly figured indeed, but the definition towards the edge of the field, say at 20° away from the centre of the apparent field of view, depends very intimately upon the construction of the eye-piece. It must be so designed as to give as flat an image as is possible consistently with freedom from astigmatism of oblique pencils. The mere size of the apparent field of view depends upon obtaining the oblique pencils of light emerging from it to cross the axis at the great possible angle, and to this end the presence of a field-lens is indispensable, which is separated from the eye-lens by a considerable interval.

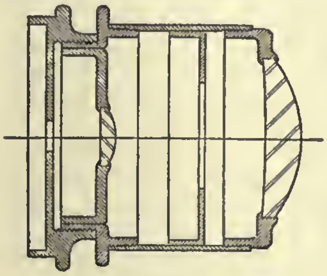

FIG. 4.

The earlier arrangement of two lenses of the Huygenian eye-piece (see MICROSCOPE) having foci with ratio of 3 to 1, gives a fairly large flat field of view approximately free from distortion of tangential lines and from coma, while the Mittenzwey variety of it (fig. 4) in which the field-lens is changed into a meniscus having radii in about the ratio of +1 to −9 gives still better results, but still not quite so good as the results obtained by using the combination of two convexo-plane lenses of the focal ratio 2 to 1.

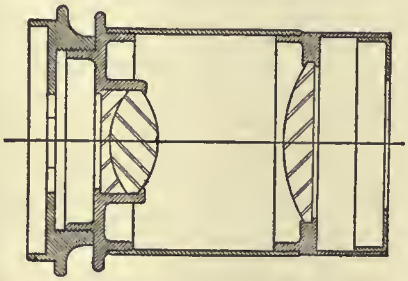

FIG. 5.

In the Ramsden eye-piece (see MICROSCOPE) the focal lengths of the two plano-convex lenses are equal, and their convexities are turned towards one another. The field-lens is thus in the principal focal plane of the eye-lens, if the separation be equal to $\frac{1}{2}(f_1+f_2)$. This is such a practical drawback that the separation is generally $\frac{2}{3}$ths or $\frac{3}{4}$ths of the theoretical, and then the primary image viewed by the eye-piece may be rather outside the field-lens, which is a great practical advantage, especially when a reticule has to be mounted in the primary focal plane, although the edge of the field is not quite achromatic under these conditions.

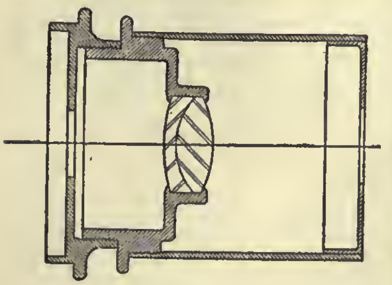

FIG. 6.

Kellner Eye-piece.—In order to secure the advantage of the principal focal plane of the eye-piece being well outside of the field-lens and at the same time to obtain a large flat field of view with oblique achromatism and freedom from coma and distortion, there is no better construction than the modified Kellner eye-piece (fig. 5) such as is generally used for prismatic binoculars. It consists of a plano-convex field-lens of crown glass and an approximately achromatic eye-lens, some distance behind it, consisting of an equi-convex crown lens cemented to a concavo-plane flint lens, the latter being next to the eye.

There are also other eye-pieces having the field-lens double or achromatic as well as the eye-lens.

In cases where it is important to get the maximum quantity of light into the eye, the field-lens is discarded and an achromatic eye-lens alone employed. This yields a very much smaller field of view, but it is very valuable for viewing feeble telescopic objects and very delicate planetary or lunar details. Zeiss and Steinheil's monocentric eye-pieces and the Cooke single achromatic eye-piece (fig. 6) are examples of this class of oculars. (H. D. T.)

Reflecting Telescope.

The following are the various forms of reflecting telescopes:—

Gregorian. The Gregorian telescope is represented in fig. 7. A A and B B are concave mirrors having a common axis and their concavities facing each other. The focus of A for parallel rays is at F, that of B for parallel rays at f—between B and F. Parallel rays falling on A A converge at F, where an image is formed; the rays are then reflected from B and converge at P, where a second and more enlarged image is formed. Gregory himself

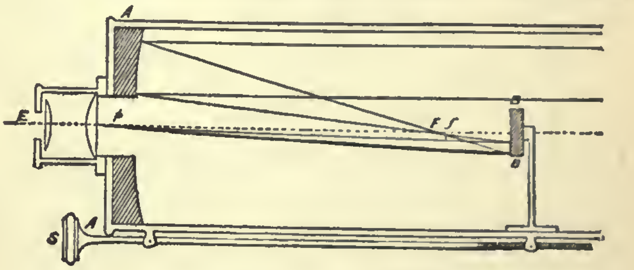

FIG. 7.—Gregorian Telescope.

showed that, if the large mirror were a segment of a paraboloid of revolution whose focus is F, and the small mirror an ellipsoid of revolution whose foci are F and P respectively, the resulting image will be plane and undistorted. The image formed at P is viewed through the eye-piece at E, which may be of the Huygenian or Ramsden type. The focal adjustment is accomplished by the screw S, which acts on a slide carrying an arm to which the mirror B is attached. The practical difficulty of constructing Gregorian telescopes of good defining quality is very considerable, because if spherical mirrors are employed their aberrations tend to increase each other, and it is extremely difficult to give a true elliptic figure to the necessarily deep concavity of the small speculum. Short appears to have systematically conquered this difficulty, and his Gregorian telescopes attained great celebrity. The use of the Gregorian form is, however, practically abandoned in the present day. The magnifying power of the telescope is $=Ff/ex$, where F and f are respectively the focal lengths of the large and the small mirror, e the focal length of the eye-piece, and x the distance between the principal foci of the two mirrors ($=Ff$ in the diagram) when the instrument is in adjustment for viewing distant objects. The images are erect.

Cassegrain. The Cassegrain telescope differs from the Gregorian only in the substitution of a convex hyperboloidal mirror for a concave ellipsoidal mirror as the small speculum. This form has two distinct advantages: (1) if spherical mirrors are employed their aberrations have a tendency to correct each other; (2) the instrument is shorter than the Gregorian, *caeteris paribus*, by twice the focal length of the small mirror. Fewer telescopes have been made of this than perhaps of any other form of reflector; but in comparatively recent years the Cassegrain has acquired importance from the fact of its adoption for the great Melbourne telescope, and from its employment in the 60-in. reflector of the Mount Wilson Solar Observatory (see below). For spectroscopic purposes the Cassegrain form has peculiar advantages, because in consequence of the less rapid convergence of the rays after reflection from the convex hyperboloidal mirror, the equivalent focus can be made very great in comparison with the length of the tube. This permits the employment of a spectroscope furnished with a collimator of long focus. The magnifying power is computed by the same formula as in the case of the Gregorian telescope.

Newtonian. The Newtonian telescope is represented in Fig. 8. A A is a concave mirror whose axis is $a\ a$. Parallel rays falling on A A converge on the plane mirror B B, and are thence reflected at right angles to the axis, forming an image in the focus of the eye-piece E. The surface of the large mirror should be a paraboloid of revolution, that of the small mirror a true optical plane. The magnifying power is $=F/e$. This form is employed in the construction of most modern reflecting telescopes. A glass prism of total reflection is sometimes substituted for the plane mirror.

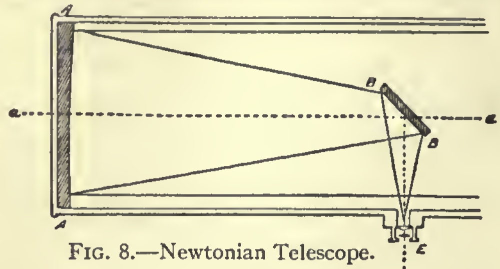

FIG. 8.—Newtonian Telescope.

The Herschelian or front view reflector is represented in fig. 9. A A is a concave parabolic mirror, whose axis *a c* is inclined to the axis of the tube *a b* so that the image of an object in the focus of the mirror may be viewed by an eye-piece at E, the angle *b a c* being equal to the angle *c a* E. This form was adopted by the elder Herschel to avoid the loss of light from reflection in the small mirror of the Newtonian telescope. The front view telescope, however, has hardly been at all employed except by the Herschels. But at the same time none but the Herschels have swept the whole sky for the discovery of faint nebulae; and

Herschelian.

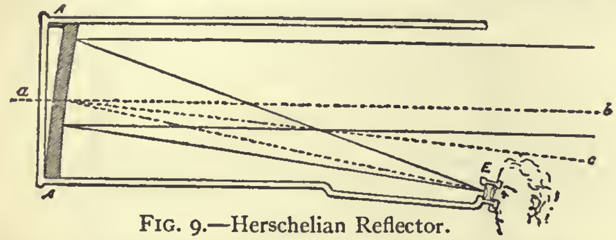

FIG. 9.—Herschelian Reflector.

probably no other astronomers have worked for so many hours on end for so many nights as they did, and they emphasize the easy position of the observer in using this form of instrument.

Construction of Specula.

The composition of metallic specula in the present day differs very little from that used by Sir Isaac Newton. Many different alloys have been suggested, some including silver, nickel, zinc or arsenic; but that which has practically been found best is an alloy of four equivalents of copper to one of tin, or the following proportions by weight: copper 252, tin 117·8. Such speculum metal is exceedingly hard and brittle, takes a fine white polish, and when protected from damp has little liability to tarnish. The process of casting and annealing, in the case of the specula of the great Melbourne telescope, was admirably described by Dr Robinson in *Phil. Trans.*, 1869, 159, p. 135. Shaping, polishing and figuring of specula are accomplished by methods and tools very similar to those employed in the construction of lenses. The reflecting surface is first ground to a spherical form, the parabolic figure being given in the final process by regulating the size of the pitch squares and the stroke of the polishing machine.

Soon after Liebig's discovery of a process for depositing a film of pure metallic silver upon glass from a salt of silver in solution, Steinheil (*Gaz. Univ. d'Augsburg*, 24th March 1856), and later, independently, Foucault (*Comptes Rendus*, vol. xliv., February 1857), proposed to employ glass for the specula of telescopes, the reflecting surface of the glass speculum to be covered with silver by Liebig's process. Those silver-on-glass specula are now the rivals of the achromatic telescope, and it is not probable that many telescopes with metal specula will be made in the future. The best speculum metal and the greatest care are no guarantee of freedom from tarnish, and, if such a mirror is much exposed, as it must be in the hands of an active observer, frequent repolishing will probably be necessary. This involves refiguring, which is the most delicate and costly process of all. Every time, therefore, that a speculum is repolished, the future quality of the instrument is at stake; its focal length will probably be altered, and thus the value of the constants of the micrometer also have to be redetermined. Partly for these reasons the reflecting telescope with metallic mirror has never been a favourite with the professional astronomer, and has found little employment out of England.[1] In England, in the hands of the Herschels, Rosse, Lassell and De la Rue it has done splendid service, but in all these cases the astronomer and the instrument-maker were one. The silver-on-glass mirror has the enormous advantage that it can be resilvered with little trouble, at small expense, and without danger of changing the figure. Glass is lighter, stiffer, less costly and easier to work than speculum metal. Silvered mirrors have also some advantage in light grasp over those of speculum metal, though, aperture for aperture, the former are inferior to the modern object-glass. Comparisons of light grasp derived from small, fresh, carefully silvered surfaces are sometimes given which lead to illusory results, and from such experiments Foucault claimed superiority for the silvered speculum over the object-glass. But Sir David Gill found from experience and careful comparison that a silvered mirror of 12-in. aperture, mounted as a Newtonian telescope (with a silvered plane for the small mirror), when the surfaces are in fair average condition, is equal in light grasp to a first-rate refractor of 10-in. aperture, or area for area as 2 : 3. This ratio will become more equal for larger sizes on account of the additional thickness of larger object-glasses and the consequent additional absorption of light in transmission.

[1] There is a noteworthy exception in the case of the 18-in. speculum-metal mirror employed by Sir William Huggins at Tulse Hill, with which a large part of his remarkable and important series of astro-spectroscopic results have been obtained. So far as we know, this mirror has never been repolished since its first installation in 1870, and still retains its admirable surface. One of Short's mirrors, made about 1760 or 1770, of 6-in. aperture, now in the possession of Sir William Huggins, has surfaces which still retain their original perfection although they have never been repolished.

Mounting of Telescopes.

The proper mounting of a telescope is hardly of less importance than its optical perfection. Freedom from tremor, ease and delicacy of movement and facility of directing the instrument to any desired object in the heavens are the primary qualifications. Where accurate differential observations or photographs involving other than instantaneous exposures have to be made, the additional condition is required that the optical axis of the telescope shall accurately and automatically follow the object under observation in spite of the apparent diurnal motion of the heavens, or in some cases even of the apparent motion of the object relative to neighbouring fixed stars.

Our limits forbid a historical account of the earlier endeavours to fulfil these ends by means of motions in altitude and azimuth, nor can we do more than refer to mountings such as those employed by the Herschels or those designed by Lord Rosse to overcome the engineering difficulties of mounting his huge telescope of 6 ft. aperture. Both are abundantly illustrated in most popular works on astronomy, and it seems sufficient to refer the reader to the original descriptions.[2]

We pass, therefore, directly to the equatorial telescope, the instrument *par excellence* of the modern extra-meridian astronomer. The article TRANSIT CIRCLE describes one form of mounting in which the telescope is simply a refined substitute for the sights or pinules of the old astronomers. The present article contains a description of the mounting of the various forms of the so-called zenith telescope. In its simplest form the mounting of an equatorial telescope consists of an axis parallel to the earth's axis, called "the polar axis"; a second axis at right angles to the polar axis called "the declination axis"; and the telescope tube fixed at right angles to the declination axis.

In Fig. 10 A A is the polar axis; the telescope is attached to the end of the declination axis; the latter rotates in bearings which are attached to the polar axis and concealed by the telescope itself. The telescope is counterpoised by a weight attached to the opposite end of the declination axis. The lower pivot of the polar axis rests in a cup-bearing at C, the upper bearing upon a strong metal casting M M attached to a stone pier S. A vertical plane passing through A A is therefore in the meridian, and the polar axis is inclined to the horizon at an angle equal to that of the latitude of the place of observation. Thus, when the declination axis is horizontal the telescope moves in the plane of the meridian by rotation on the declination axis only. Now, if a graduated circle B B is attached to the declination axis, together with the necessary verniers or microscopes V V for reading it (see TRANSIT CIRCLE), so arranged that when the telescope is turned on the declination axis till its optical axis is parallel to A A the vernier reads 0° and when at right angles to A A 90°, then we can employ the readings of

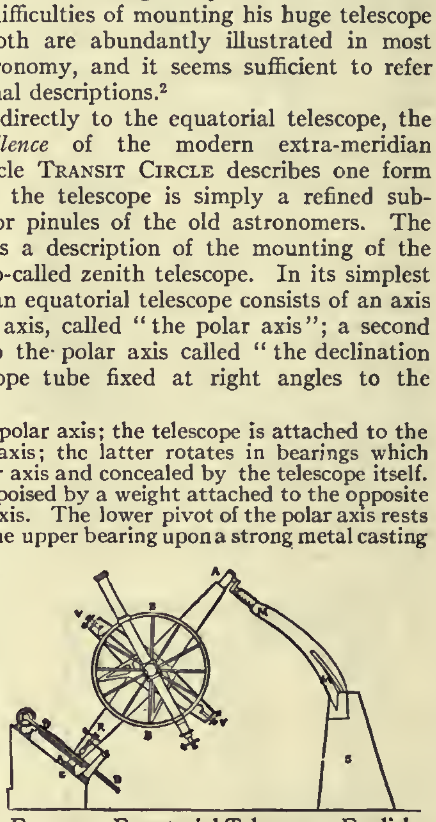

FIG. 10.—Equatorial Telescope. English form.

[2] Herschel, *Phil. Trans.*, 1795, 85, p. 347; Rosse, *Phil. Trans.* 1840, p. 503; 1861, p. 681.

this circle to measure the polar distance of any star seen in the telescope, and these readings will also be true (apart from the effects of atmospheric refraction) if we rotate the instrument through any angle on the axis A A. Thus one important attribute of an equatorially mounted telescope that, if it is directed to any fixed star, it will follow the diurnal motion of that star from rising to setting by rotation of the polar axis only. If we now attach to the polar axis a graduated circle D D, called the "hour circle," of which the microscope or vernier R reads 0^h when the declination axis is horizontal, we can obviously read off the hour angle from the meridian of any star to which the telescope may be directed at the instant of observation. If the local sidereal time of the observation is known, the right ascension of the star becomes known by adding the observed hour angle to the sidereal time if the star is west of the meridian, or subtracting it if east of the meridian. Since the transit circle is preferable to the equatorial for such observations wherein great accuracy is required, the declination and hour circles of an equatorial are employed, not for the determination of the right ascensions and declinations of celestial objects, but for directing the telescope with ease and certainty to any object situated in an approximately known position, and which may or may not be visible to the naked eye, or to define approximately the position of an unknown object. Further, by causing the hour circle, and with it the polar axis, to rotate by clockwork or some equivalent mechanical contrivance, at the same angular velocity as the earth on its axis, but in the opposite direction, the telescope will, apart from the effects of refraction, automatically follow a star from rising to setting.

Types of Equatorials.—Equatorial mountings may be divided into six types. (A) The pivots or bearings of the polar axis are placed at its extremities. The declination axis rests on bearings attached to opposite sides of the polar axis. The telescope is attached to one end of the declination axis, and counterpoised by a weight at the other end, as in fig. 10. (B) The polar axis is supported as in type A; the telescope is placed between the bearings of the declination axis and is mounted symmetrically with respect to the polar axis; no counterpoise is therefore requisite. (C) The declination axis is mounted on the prolongation of the upper pivot of the polar axis; the telescope is placed at one end of the declination axis and counterpoised by a weight at the other end. (D) The declination axis is mounted on a forked piece or other similar contrivance attached to a prolongation of the upper pivot of the polar axis; the telescope is mounted between the pivots of the declination axis. (E) The eye-piece of the telescope is placed in the pivot of the polar axis; a portion or the whole of the axis of the telescope tube coincides with the polar axis. (F) The telescope is fixed and the rays are reflected along its axis from an external mirror or mirrors. Mountings of types A and B—that is, with a long polar axis supported at both ends—are often called the "English mounting," and type C, in which the declination axis is placed on the extension of the upper pivot of the polar axis, is called the "German mounting," from the first employment of type C by Fraunhofer. A description of some of the best examples of each type will illustrate their relative advantages or peculiarities.

Type A.—Fig. 10 may be taken as a practical example of the earlier equatorials as made by Troughton in England and afterwards by Gambey for various Continental observatories. In the *Phil. Trans.* for 1824 (part 3, pp. 1–412) will be found a description by Sir John Herschel and Sir James South of the equatorial telescope which they employed in their measurements of double stars. The polar axis was similar in shape to that of fig. 10 and was composed of sheets of tinned iron. In Smyth's celebrated Bedford telescope the polar axis was of mahogany. Probably the best example of this type of mounting applied to a refractor is that made by the elder Cooke of York for Fletcher of Tarnbank; the polar axis is of cast iron and the mounting very satisfactory and convenient, but unfortunately no detailed description has been published. In recent years no noteworthy refractors have been mounted on this plan; but type A has been chosen by Grubb for the great Melbourne reflector, of 48-in. aperture, with marked ingenuity of adaptation to the peculiar requirements of the case. Fig. 11 shows the whole instrument on a small scale with the telescope directed to the pole, and the hour circle set 6^h from the meridian.

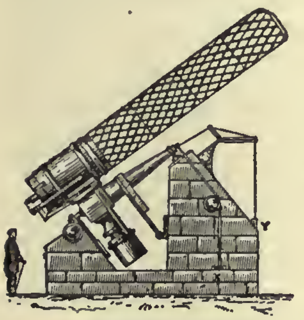

FIG. 11.—Melbourne Reflector.

Great Melbourne telescope.

Type B.—The most important examples of type B are Airy's equatorial at Greenwich (originally made to carry a telescope of 13-in. aperture, but now fitted with a telescope by Grubb of 28-in. aperture), and the photographic equatorials of 13-in. aperture employed at Paris and other French observatories, of which the object-glasses were made by the brothers Henry and the mountings by Gautier of Paris.

These instruments have done admirable work in connexion with the great international undertaking, the *Carte du Ciel.* The general construction will be understood from fig. 12. The double polar axis is composed of hollow metal beams of triangular section. The hour circle has two toothed circles cut upon it, one acted upon by a worm screw mounted on the pier and driven by clockwork, the other by a second worm screw attached to the polar axis, which can be turned by a handle in the observer's hand and thus a slow movement can be given to the telescope in right ascension independently of the clock. Slow motion in declination can be communicated by a screw acting on a long arm, which latter can be clamped at pleasure to the polar axis. An oblong metallic box fitted with pivots, whose bearings are attached to the triangular beams, forms the tube for two parallel telescopes; these are separated throughout their length by a metallic diaphragm. The chromatic aberration of the object-glass of one of these telescopes is corrected for photographic rays, and the image formed by it is received on a highly sensitive photographic plate. The other telescope is corrected for visual rays and its image is formed on the plane of the spider-lines of a filar micrometer. The peculiar form of the tube is eminently suited for rigid preservation of the relative parallelism of the axes of the two telescopes, so that, if the image of a certain selected star is retained on the intersection of two wires of the micrometer, by means of the driving clock, aided by small corrections given by the observer in right ascension and declination (required on account of irregularity in the clock movement, error in astronomical adjustment of the polar axis, or changes in the star's apparent place produced by refraction), the image of a star will continue on the same spot of the photographic film during the whole time of exposure. In these telescopes the photographic object-glass has an aperture of 13 in. and the visual object-glass of 10 in. Both telescopes have the same focal length, viz. 11·25 ft., so that, in the image produced, 1 mm. is = $1'$ of arc. An excellent mounting of type B, made by T. Cooke & Sons of York, has been employed by Franklin Adams for making his maps of the sky.

FIG. 12.—Paris Observatory Instrument.
After an illustration in *La Nature*, by permission of Masson et Cie.

Type C.—Many more telescopes have been made of type C than of any other, and this form of mounting is still most generally employed for the mounting of modern refractors. Fraunhofer's *chef-d'oeuvre*, the great Dorpat refractor, made for Otto Struve about 1820, had a mounting of this type, and was the first equatorial of any importance to be provided with clockwork. The instrument, shown in fig. 13, is described in detail by Struve (*Beschreibung des auf der Sternwarte zu Dorpat befindlichen grossen Refractors von*

Fraunhofer, Dorpat, 1825), and was an enormous advance upon all previous telescopes for micrometric research. In the hands of Struve results were obtained by it which in combined quality and quantity had never before been reached. Its success was such that the type of Fraunhofer's telescope became stereotyped for many years not only by Fraunhofer's successors but throughout Germany. When, twelve years afterwards, Struve ordered the 15-in. refractor for the new observatory at Pulkovo, the only important change made by Fraunhofer's successors was, at Struve's suggestion, the substitution of a stone pier for the wooden stand in the original instrument.

Both the Dorpat and the Pulkovo refractors are defective in rigidity, especially in right ascension. The declination circle is most inconvenient of access, and slow motion in declination can only be effected when the instrument is clamped by a long and inconvenient handle; so that, practically, clamping in declination was not employed. The slow motion in right ascension is defective, being accomplished in the Dorpat refractor by changing the rate of the clock, and in the Pulkovo refractor by a handle which, when used, affects very injuriously the rate of the clock for the time being. Struve's skill as an observer was such that he used to complete the bisection on the fixed wire of the micrometer by a pressure of the finger on the side of the tube—a method of proved efficiency in such hands, but plainly indicative of the want of rigidity in the instrument and of the imperfection of the slow motions (see MICROMETER).

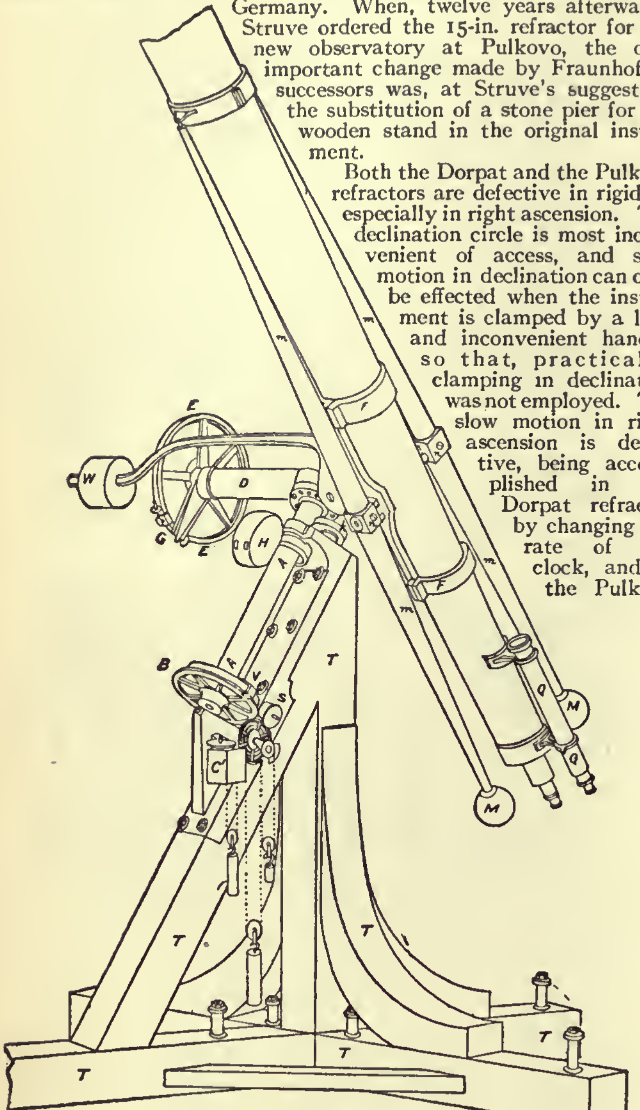

FIG. 13.—Dorpat Refractor.

The driving circle is also much too small, so that a very slight mechanical freedom of the screw in the teeth involves a large angular freedom of the telescope in right ascension, while its position at the lower end of a too weak polar axis tends to create instability from torsion of that axis. Strange to say, the wooden tube long retained its place in German telescope-mountings.

About 1840 a great advance was made by the Repsolds of Hamburg in the equatorial mounting of the Oxford heliometer. The driving circle was greatly increased in diameter and placed at the upper end of the polar axis, and both the polar and declination axes were made much stronger in proportion to the mass of the instrument they were designed to carry. (A figure of the instrument is given in the Oxford *Observations* for 1850.) About 1850 Thomas Cooke of York began his career as a maker of equatorial telescopes. The largest example of his work is the refractor of 24-in. aperture, originally made for the private observatory of Robert Stirling Newall at Gateshead, Northumberland, and afterwards presented by him to the University Observatory, Cambridge. Cooke's mounting is admirable for its symmetry and simplicity of design, its just apportioning of strength, and a general suitability of means to ends.

It is not a little curious that the obvious improvement of transferring the declination axis as well as the declination-clamp to the telescope end of the declination axis was so long delayed; we can explain the delay only by the desire to retain the declination circle as a part of the counterpoise. We believe the first important equatorials in which the declination was read from the eye-end were the 15-in. by Grubb and the 6-in. by Cooke, made for the observatory of Lord Crawford (Lord Lindsay) at Dun Echt, Aberdeenshire, about 1873. The plan is now universally adopted. Telescopes of such dimensions can be conveniently directed to any object by the circles without the observer being under the necessity to climb a special ladder. But when much larger instruments are required the hour circle becomes inaccessible from the floor, and means have to be devised for reading both circles from the eye-end. This was first accomplished by Grubb in the great refractor of 27-in. aperture which he constructed for the Vienna observatory, represented in section in fig. 14. The observer's eye is applied to the small telescope E, which (by means of prisms numbered 1, 2, 3, 4) views the vernier attached to the cross-head simultaneously with the hour circle attached to the upper end of the polar axis. Light to illuminate the vernier and circle is thrown from the lamp L upon prism 4 by the prisms 6 and 5. Prism 1 is in the axis of the declination circle and always reflects rays along that axis, whatever the position of the telescope may be, whilst the prisms 2, 3, 4, 5 and 6 are attached to the cross-head and therefore preserve their relative positions to each other. Through the eye-piece of the bent[1] telescope E′ another hour circle attached to the lower end of the polar axis can be seen; thus an assistant is able to direct the telescope by a handle at H to any desired hour angle. A slight rotatory motion of the telescope E on its axis enables the vernier of the declination circle to be read through prism 1. The leading features of this fine instrument represent those of all Grubb's large telescopes. The mode of relieving the friction of the declination axis is similar to that employed in the Melbourne telescope and in the account of the Vienna telescope published by Grubb. The end friction of the polar axis is relieved by a ring of conical rollers shown in section beside the principal figure.

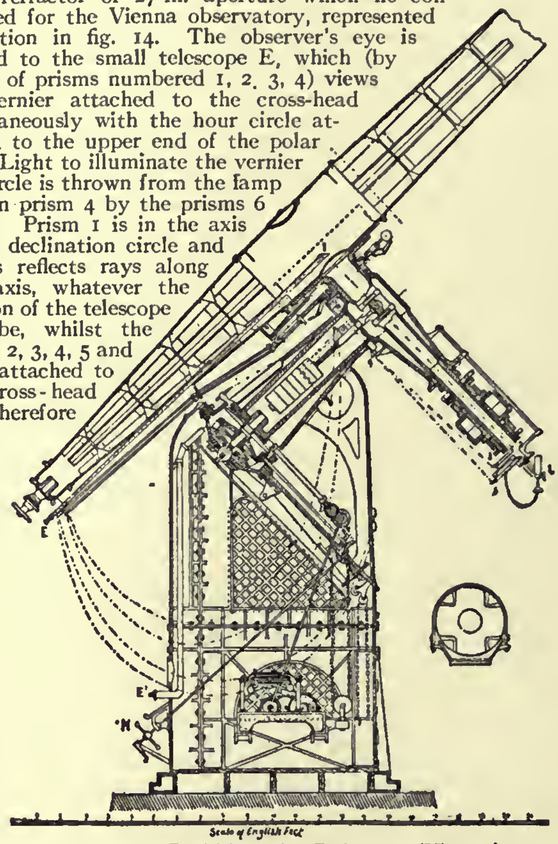

FIG. 14.—Grubb's 27-in. Refractor (Vienna).

From this point we must condense farther description into critical remarks on a few typical modern instruments.

Repsolds' small equatorial.

(1) *Telescopes of Moderate Size for Micrometric Research Only.*—Fig. 15 shows the mounting of the 8-in. refractor, of 9-ft. focal length, at the private observatory of Dr Engelmann, Leipzig. The object-glass is by Messrs Clark of Cambridge, Mass., the mounting by the Repsolds of Hamburg. The declination circle reads from the eye-end, and four handles for clamping and slow motion in right ascension and declination are situated near the observer's hands. The tube is of sheet steel, light, stiff, and free from tremor. The eye-end carries the micrometer with an illuminating apparatus similar to that described under MICROMETER. The lamp near the eye-end illuminates the field or the wires at pleasure, as well as the position circle of the micrometer and the declination circle; a separate lamp illuminates the hour circle. An excellent feature is the short distance between the eye-piece and the declination axis, so that

[1] In the bent telescope refracting prisms are employed at the corners to change the direction of the rays.

the observer has to follow the eye-end in a comparatively small circle; another good point is the flattening of the cast-iron centre-piece of the tube so that the flange of the declination axis is attached as near to the axis of the telescope tube as is consistent with free passage of the cone of rays from the object-glass. The substitution of small incandescent electric lamps is an improvement now universally adopted.

(2) *Telescopes for General Purposes.*—The modern equatorial should, for general purposes, be capable of carrying spectroscopes of considerable weight, so that the proportional strength of the axes and the rigidity of the instrument have to be considerably increased. The original mounting of the Washington refractor of 26-in. aperture and 32½-ft. focal length (described in *Washington Observations*, 1874, App. 1) was in these respects very defective, the polar and declination axes being only 7 in. in diameter.

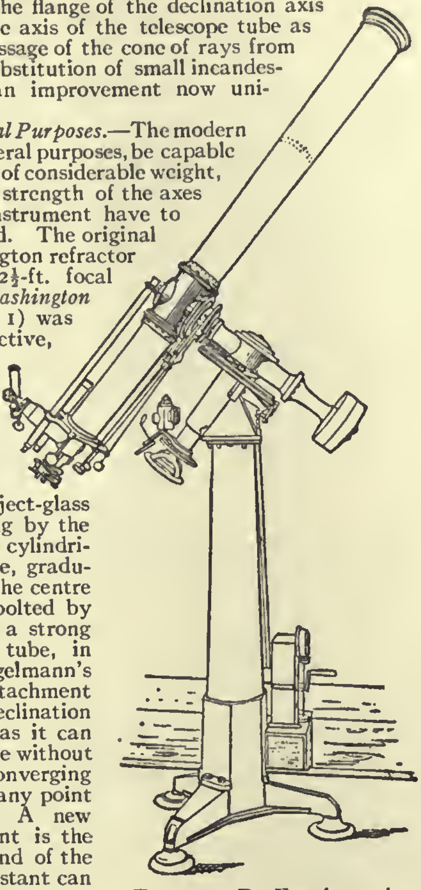

FIG. 15.—Dr Engelmann's 8-in. Refractor.

The great Pulkovo refractor (fig. 16) erected in 1885 is of 30-in. aperture and 45-ft. focal length. The object-glass is by Clark, the mounting by the Repsolds. The tube is cylindrical, of riveted steel plate, graduated in thickness from the centre to its extremities, and bolted by very powerful flanges to a strong short cast-iron central tube, in which, as in Dr Engelmann's telescope (fig. 15), the attachment to the flange of the declination axis is placed as close as it can be to the axis of the tube without interfering with rays converging from the object-glass to any point in the field of view. A new feature in this instrument is the platform at the lower end of the polar axis, where an assistant can view the hour circle by one eye-piece and the declination circle by another (looking up the perforated polar axis), and where he can also set the telescope to any hour angle by one wheel, or to any declination by a second, with the greatest ease. The observer at the eye-end can also read off the hour and declination circles and communicate quick or slow motions to the telescope both in right ascension and declination by conveniently placed handles. The eye end presents an appearance too complicated to be figured here; it has a micrometer and its illumination for the position circle, a micrometer head, and a bright or dark field, clamps in right ascension and declination and quick and slow motion in the same, a finder, microscopes for reading the hour and declination circles, an illuminated dial showing sidereal time and driven by an electric current from the sidereal clock, and counter weights which can be removed when a spectroscope or other heavy appliance is added. All these, although making up an apparently complicated apparatus, are conveniently

Pulkovo refractor.

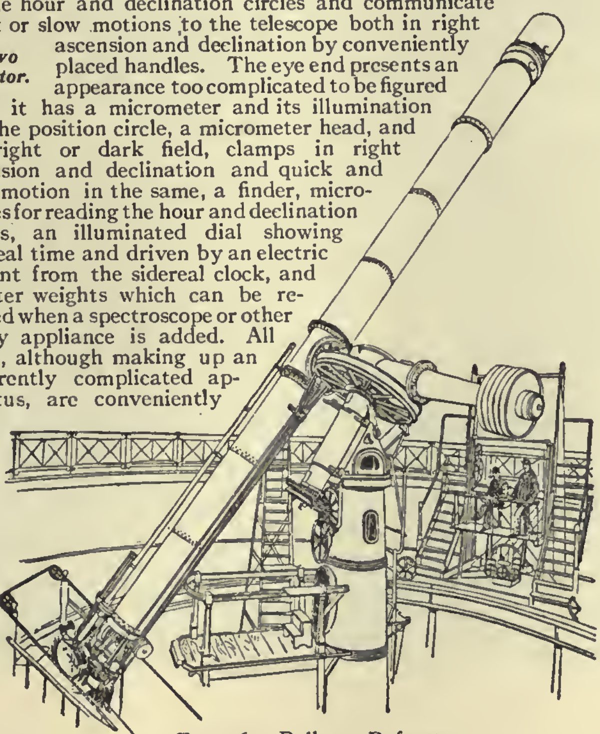

FIG. 16.—Pulkovo Refractor.

arranged, and are all necessary for the quick and easy working of so large an instrument. We have the authority of Otto Struve for stating that in practice they are all that can be desired. There is in this instrument a remarkably elegant method of relieving the friction of the polar axis. Let A A (fig. 17) be a section of the polar axis; it is then easy to adjust the weight P attached to its lower end so that the centre of gravity X of the whole moving parts of the instrument shall be in the vertical (V V) of a line passing through the apex of the hollowed flange $p\ q$ at q, which flange forms part of the polar axis. If now a wheel W is forced up against q with a pressure equal to the weight of the moving part of the instrument, the whole weight of the moving part would rest upon W in unstable equilibrium; or if a pressure R, less than W, is employed, we have the end friction on the lower bearing removed to an extent $=$ R sin ϕ, and the friction on the bearings of the upper pivot removed to the extent of F cos ϕ,—where ϕ is the latitude of the place. The wheel W is therefore mounted on a guided rod, which is forced upwards by suitable levers and weights, and this relief of pressure is precisely proportional to the pressure on the respective bearings. The Repsolds find it unnecessary to relieve the friction of the declination axis.

In such large telescopes it becomes a matter of the first importance to provide means of convenient access to the eye-end of the instrument. This the Repsolds have done in the Pulkovo telescope by means of two platforms, as shown in fig. 16. These platforms are capable of easy motion so that the astronomer may be conveniently situated for observing an object at any azimuth or altitude to which the telescope may be directed. For the great refractor more recently erected at Potsdam, Messrs Repsold arranged a large platform mounted on a framework which is moved in azimuth by the dome, so that the observer on the platform is always opposite the dome-opening. This framework is provided with guides on which the platform, whilst preserving its horizontality, is raised and lowered nearly in an arc of a circle of which the point of intersection of the polar and declination axes is the centre. The rotation of the dome, and with it the platform-framework, is accomplished by means of electric motors, as also is the raising and lowering of the platform on its framework. The current is supplied by accumulators, and the switch-board is attached to the platform in a position convenient for use by the astronomer or his assistant.

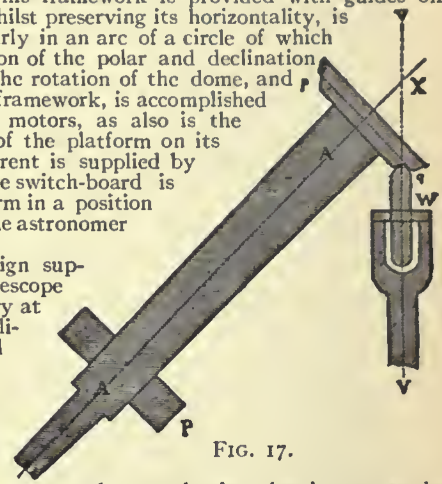

FIG. 17.

In the original design supplied for the 36-in. telescope of the Lick Observatory at Mount Hamilton, California, Grubb suggested that the whole floor, 70 ft. in diameter, should be raised and lowered by water power, under control of the observer by means of electric keys which act on secondary mechanism that in turn works the valves and reversing gear of the water engines. Other water engines, similarly connected, with keys at the observer's hands, rotate the dome and perform the quick motions in right ascension and declination. (An illustration showing these arrangements appeared in *The Engineer* of July 9, 1886.) Grubb's suggestion of the "rising floor" was adopted, although his original plans for the mounting were not carried out; the construction of the mounting, dome, floor, &c., having been entrusted to Messrs Warner & Swasey of Cleveland, Ohio, U.S.A. It has been contended that it is undesirable to move so great a mass as a floor when a platform alone is required to carry the observer. But a floor, however heavy, suspended by three wire ropes and properly balanced over large, well-mounted pulleys, requires an amount of energy to work it which does not exceed that required to operate a platform of moderate dimensions, and there is a freedom, a safety and a facility of working with a complete floor which no partial platform can give. A floor can be most satisfactorily operated by hydraulic means, a platform cannot be so well worked in this way. The best floor mounting we know of is that designed by O. Chadwick for the Victoria Telescope of the Cape Observatory. An account of it will be found in the *History and Description of the Cape Observatory*. This floor can be raised at the rate of 1 ft. per second or as slowly as the observer desires—whilst in all the large platforms we have seen (Potsdam and Paris), the rate of shift is tedious and time-consuming.

The largest refracting telescope in active use is the Yerkes telescope, with an object-glass of 40-in. diameter by Alvan Clark & Son of Cambridge, U.S.A., and with a mounting, dome and rising floor by Warner & Swasey of Cleveland, Ohio, U.S.A. The reader will gather a good general idea of the design from fig. 16. The eye-end is shown on the plate, fig. 25.

The chief defect in equatorial mountings of type C is that in general they are not capable of continued observing much past the meridian without reversal. This is an unquestionable drawback when long exposures near the meridian are required. By the

use of an overhanging polar axis the difficulty can be overcome; it has been successfully adopted by Repsolds for their astrographic equatorials of 13-in. aperture and 11·25-ft. focus, and on a much smaller scale by Warner & Swasey for the Bruce telescope of 10-in. aperture and 50-in. focus, made for the Yerkes Observatory. The

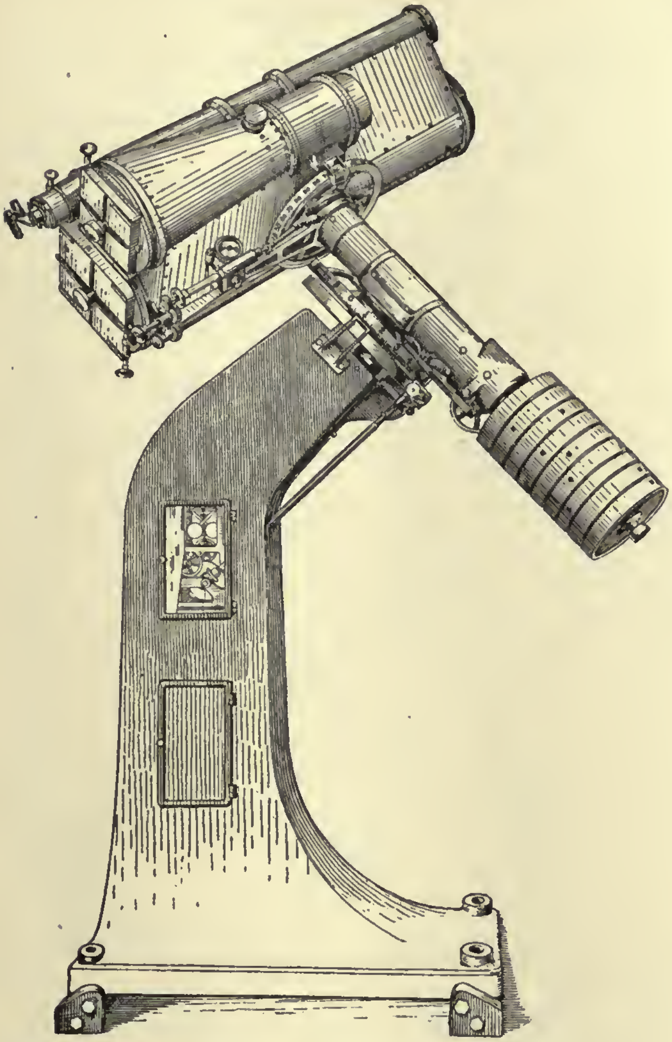

FIG. 19.—Bruce Telescope, made for the Yerkes Observatory.

From Professor Hale's *The Study of Stellar Evolution*, by permission of the University of Chicago Press.

latter is shown in fig. 19. Stability in this method of mounting can only be secured by excessive weight and rigidity in the support of the overhanging axis. In the case of the Victoria telescope (24-in. aperture and 22½-ft. focus) mounted at the Cape of Good Hope on this plan, it has been found necessary to add supporting stays where great rigidity is required, and thus to sacrifice continuous circum-meridian motion for stars between the zenith and the elevated pole.

Type D.—The first important equatorial of type D was the 4-ft. reflecting telescope of Lassell (*Mem. R.A.S.*, xxxvi. 1–4), and later Lord Rosse's 36-in. reflecting telescope at Birr Castle (*Phil. Trans.*, clxxi. 153), and A. Common's 36-in. reflecting telescope mounted by him at Ealing (*Mem. R.A.S.*, xlvi. 173–182). In Lassell's instrument (a reflector of the Newtonian type) the observer is mounted in the open air on a supplementary tower capable of motion in any azimuth about the centre of motion of the telescope, whilst an observing platform can be raised and lowered on the side of the tower. In Lord Rosse's instrument (also of the Newtonian type) the observer is suspended in a cage near the eye-piece, and the instrument is used in the open air. Common's telescope presents many ingenious features, especially the relief-friction by flotation of the polar axis in mercury, and in the arrangements of the observatory for giving ready access to the eye-piece of the telescope.

Type C seems indeed to be the type of mounting most suitable for reflecting telescopes, and this form has been adopted for the 60-in. reflector completed by G. W. Ritchey, under the direction of Professor G. E. Hale, for the Mount Wilson Solar Observatory. The instrument is shown in fig. 20, and its design is unquestionably the most perfect yet proposed for modern astrophysical research.

The declination axis is here represented by what are practically the trunnions or pivots of the tube, resting in bearings which are supported by the arms of a very massive cast-iron fork bolted to the upper end of the polar axis. This axis is a hollow forging of nickel steel, of which the accurately turned pivots rest on bearings attached to cast-iron uprights bolted upon a massive cast-iron base plate. The base plate rests upon levelling screws which permit the adjustment of the polar axis to be made with great precision. The combined overhanging weight of the cast-iron fork, the mirror and tube is so great, that without a very perfect relief-friction system the instrument could not be moved in right ascension with any approach to practical ease. But a hollow steel float, 10 ft. in diameter, is bolted to the upper end of the polar axis just below the fork. This float dips into a tank filled with mercury so that practically the entire instrument is floated by the mercury, leaving only sufficient pressure on the bearings to ensure that the pivots will remain in contact with them. The 60-in. silver-on-glass mirror (weighing about one ton) rests at the lower end of the tube on a support-system consisting of a large number of weighted levers which press against the back of the glass and distribute the load. Similar weighted levers around the circumference of the mirror provide the edge support. The telescope is moved in right ascension and declination by electric motors controlled from positions convenient for the observer. The driving clock moves the telescope in right ascension by means of a worm-gear wheel, 10 ft. in diameter, mounted on the polar axis.

The 60-in. mirror is of 25-ft. focus, but for certain classes of work it is desirable to have the advantage of greater focal length. For this purpose the telescope can be used in the four different ways shown in fig. 21.

(1) As a Newtonian reflector, fig. 21 (*a*), the converging rays from the 60-in. mirror being reflected to the side of the tube where

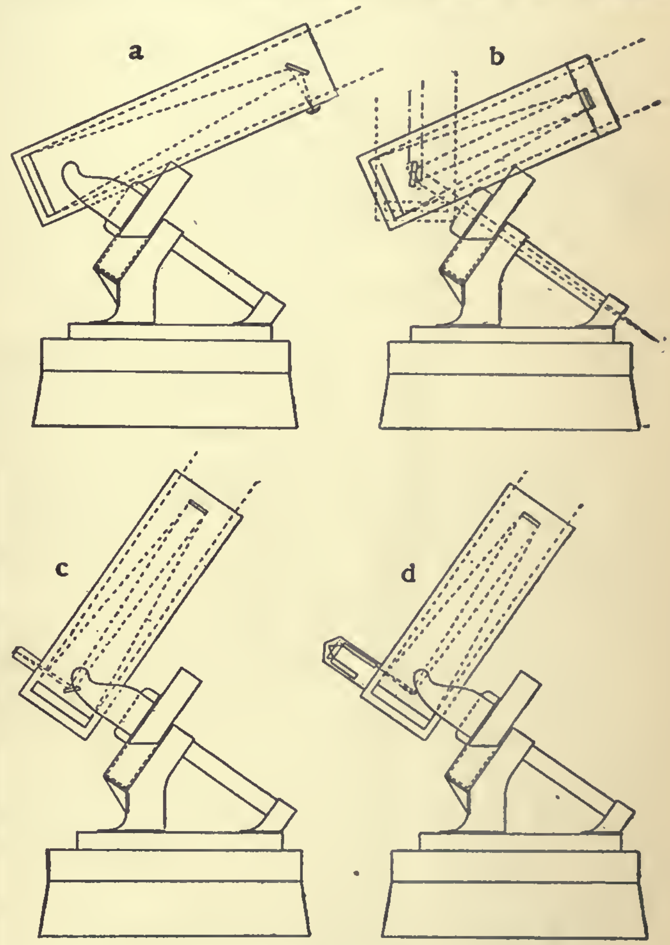

FIG. 21.

From Professor Hale's *The Study of Stellar Evolution*, by permission of the University of Chicago Press.

the image is formed, and where it may be photographed or viewed with an eye-piece. In this case the image is formed without secondary magnification and the focal length is 25 ft.

(2) As a Cassegrain reflector, fig. 21 (*b*), in which case the upper section of the tube bearing the plane mirror is removed and a shorter section substituted for it. This latter carries a hyperboloidal

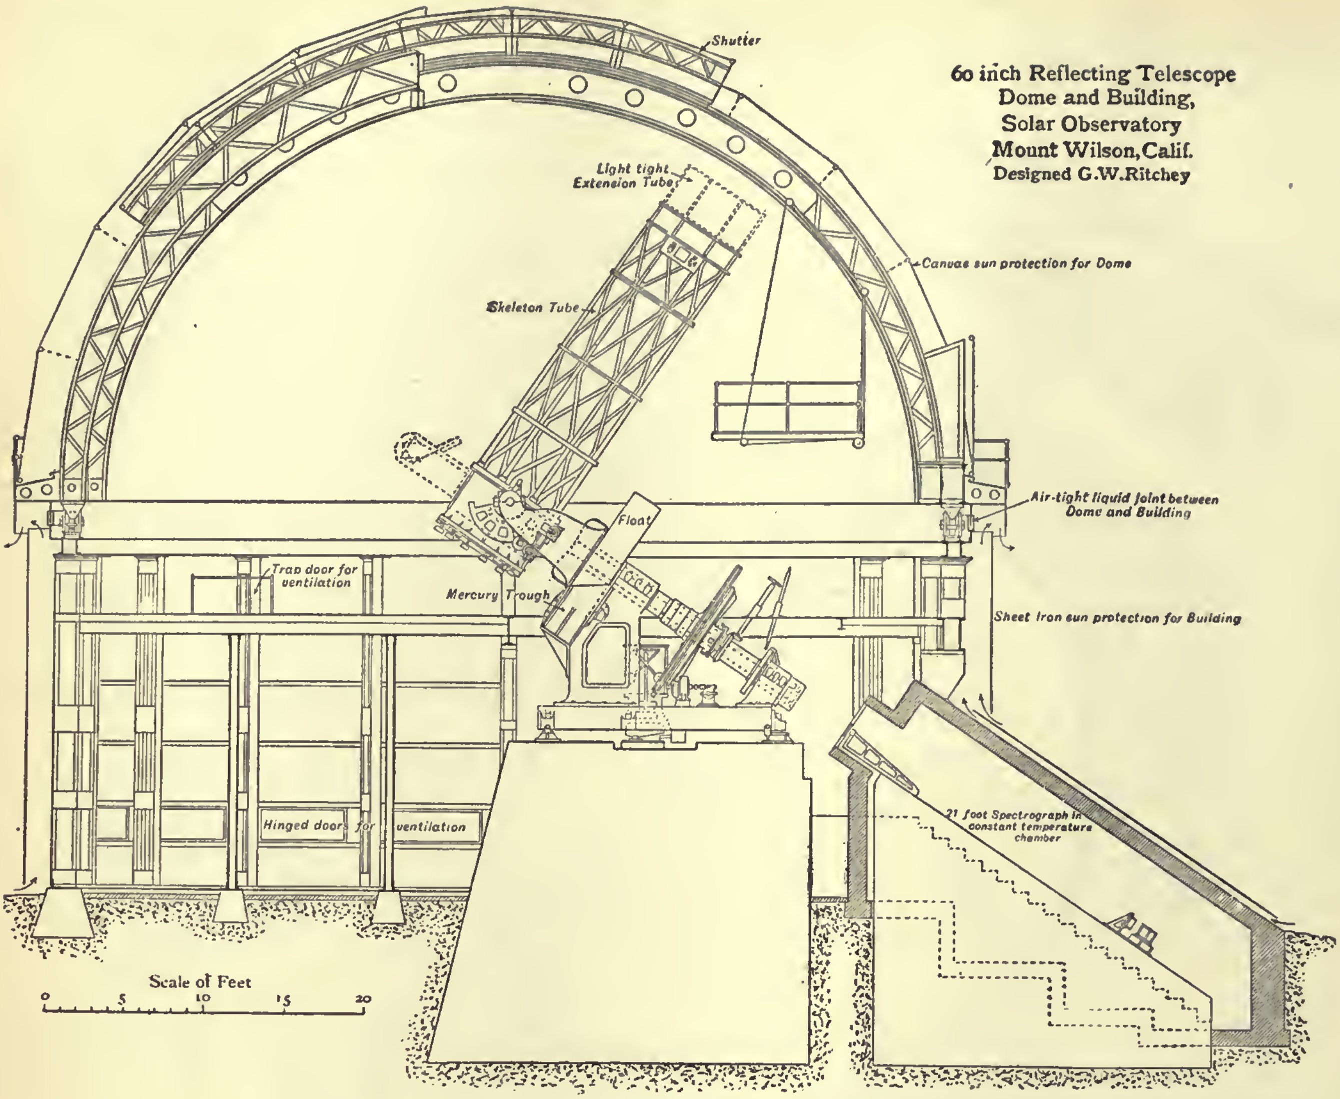

FIG. 20.

From Professor Hale's *The Study of Stellar Evolution*, by permission of the University of Chicago Press.

mirror, which returns the rays towards the centre of the large mirror and causes them to converge less rapidly. They then meet a small plane mirror supported at the point of intersection of the polar and declination axes, whence they are reflected down through the hollow polar axis as shown in fig. 2, and come to focus on the slit of the powerful spectroscope that is mounted on a pier in the chamber of constant temperature as shown in fig. 20. In this case the equivalent focal length is 150 ft.

(3) As a Cassegrain reflector, for photographing the moon, planets or very bright nebulae on a large scale, as shown in fig. 21 (*c*), with an equivalent focal length of 100 ft.

(4) As a Cassegrain reflector, for use with a spectroscope mounted in place of the photographic plate, fig. 21 (*d*); in this case a convex mirror of different curvature is employed, the equivalent focus of the combination being 80 ft.

Loewy's equatorial coudé.

Type E.—In the *Comptes Rendus* for the year 1883, vol. 96, pp. 735–741, Loewy gives an account of an instrument which he calls an "equatorial coudé," designed (1) to attain greater stability and so to measure larger angles than is generally possible with the ordinary equatorial; (2) to enable a single astronomer to point the telescope and make observations in any part of the sky without changing his position; (3) to abolish the usual expensive dome, and to substitute a covered shed on wheels (which can be run back at pleasure), leaving the telescope in the open air, the observer alone being sheltered. These conditions are fulfilled in the manner shown in fig. 22. E P is the polar axis, rotating on bearings at E and P. The object-glass is at O, the eye-piece at E. There is a plane mirror at M, which reflects rays converging from the object-glass to the eye-piece at E. A second mirror N, placed at 45° to the optical axis of the object-glass, reflects rays from a star at the pole; but by rotating the box which contains this mirror on the axis of its supporting tube T a star of any declination can be observed, and by combining this motion with rotation of the polar axis the astronomer seated at E is able to view any object whatever in the visible heavens, except circumpolar stars near lower transit. An hour circle attached to E P and a declination circle attached to the box containing the mirror N, both of which can be read or set from E, complete the essentials of the instrument. There must be a certain loss of light from two additional reflections; but that could be tolerated for the sake of other advantages, provided that the mirrors could be made sufficiently perfect optical planes. By making the mirrors of silvered glass, one-fourth of their diameter in thickness, the Henrys have not only succeeded in mounting them with all necessary rigidity free from flexure but have given them optically true plane surfaces, notwithstanding their large diameters, viz., 11 and 15·7 in. Sir David Gill tested the equatorial coudé on double stars at the Paris Observatory in 1884, and his last doubts as to the practical value of the instrument were dispelled. He has never seen more perfect optical definition in any of the many telescopes he has employed, and certainly never measured a celestial object in such favourable conditions of physical comfort. The easy position of the observer, the convenient position of the handles for quick and slow motion, and the absolute rigidity of the mounting leave little to be desired. In a much larger

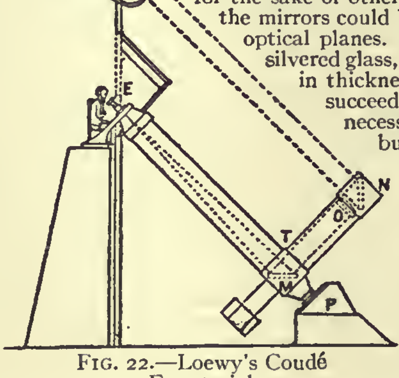

FIG. 22.—Loewy's Coudé Equatorial.

instrument of the same type subsequently mounted at Paris, and in like instruments of intermediate size mounted at other French observatories, the object-glass is placed outside the mirror N, so that both the silvered mirrors are protected from exposure to the outer air.

A modification of Loewy's equatorial coudé has been suggested by Lindemann (*Astr. Nachr.*, No. 3935); it consists in placing both the mirrors of Loewy's "equatorial coudé" at the top of the polar axis instead of the lower end of it. By this arrangement the long cross tube becomes unnecessary, and neither the pier nor the observatory obstruct the view of objects above the horizon near lower transit as is the case in Loewy's form. The reflected rays pass down the tube from the direction of the elevated pole instead of upward towards that pole. The observer is, therefore, at the bottom of the tube instead of the top and looks upward instead of downward. The drawbacks to this plan are (1) the necessarily large size of the upper pivot (viz. the diameter of the tube) and of the lower pivot (which must be perforated by a hole at least equal in diameter to the photographic field of the telescope), conditions which involve very refined arrangements for relief of friction, and (2) the less comfortable attitude of looking upward instead of downward. The plan, however, would be a very favourable one for spectroscopic work and for the convenient installation of an underground room of constant temperature. The difficulties of relief friction could probably be best overcome by a large hollow cylinder concentric with the polar axis fixed near the centre of gravity of the whole instrument and floated in mercury, on the plan adopted in the Mount Wilson 60-in. reflector already described, but in this case the floating cylinder would be below and not above the upper bearing.

The Grubb equatorial at Cambridge.

In 1884 Sir Howard Grubb (*Phil. Trans. R. Dub. Soc.*, vol. iii. series 2, p. 61) proposed a form of equatorial telescope of which an excellent example was erected at Cambridge (Eng.) in 1898. The instrument in some respects resembles the equatorial coudé of Loewy, but instead of two mirrors there is only one. A flanged cast-iron box, strongly ribbed and open on one side, forms the centre of the polar axis. One pivot of the polar axis is attached to the lower end of this box, and a strong hollow metal cone, terminating in the other pivot, forms the upper part of the polar axis. The declination axis passes through the two opposite sides of the central box. Upon an axis concentric with the declination axis is carried a plane mirror, which is geared so as always to bisect the angle between the polar axis and the optical axis of the telescope. If then the objective tube is directed to any star, the convergent beam from the object-glass is received by the plane mirror from which it is reflected upwards along the polar axis and viewed through the hollow upper pivot. Thus, as in the equatorial coudé, the observer remains in a fixed position looking down the polar tube from above. He is provided with quick and slow motions in right ascension and declination, which can be operated from the eye-end, and he can work in a closed and comfortably heated room. A large slot has to be cut in the cone which forms the upper part of the polar axis, in order to allow the telescope to be pointed nearer to the pole than would otherwise be possible; even so stars within 15° of the pole cannot be observed. An illustrated preliminary description of the instrument is given by Sir Robert Ball (*Mon. Not. R.A.S.*, lix. 152). The instrument has a triple photo-visual Taylor object-glass of 12½ in. aperture and 19·3-ft. focal length.

Type F.—In all the previously described types of telescope mounting the axis of the instrument is either pointed directly at the object or to the pole; in the latter case the rays from the star under observation are reflected along the polar axis by a mirror or mirrors attached to or revolving with it. Equatorials of types A, B, C and D have the advantage of avoiding interposed reflecting surfaces, but they involve inconveniences from the continual motion of the eye-piece and the consequent necessity for providing elaborate observing stages or rising floors. In those of type E the eye-piece has a fixed position and the observer may even occupy a room maintained at uniform temperature, but he must submit to a certain loss of light from one or more reflecting surfaces, and from possible loss of definition from optical imperfection or flexure of the mirror or mirrors. In all these types the longer the telescope and the greater its diameter (or weight) the more massive must be the mounting and the greater the mechanical difficulties both in construction and management.

But if it be possible to mount a fixed telescope by which a solar or stellar image can be formed within a laboratory we give the following advantages:—(1) There is no mechanical limit to the length of the telescope; (2) the clockwork and other appliances to move the mirror, which reflects the starlight along the axis, are much lighter and smaller than those required to move a large telescope; (3) the observer remains in a fixed position, and spectroscopes of any weight can be used on piers within the laboratory; and (4) the angular value of any linear distance on a photographic plate can be determined by direct measurement of the distance of the photographic plate from the optical centre of the object-glass. The difficulty is that the automatic motion of a single mirror capable of reflecting the rays of any star continuously along the axis of a fixed horizontal telescope, requires a rather complex mechanism owing to the variation of the angle of reflexion with the diurnal motion.

The Paris refractor (1900).

Foucault appears to have been the first to appreciate these advantages and to face the difficulty of designing a siderostat which, theoretically at least, fulfils the above-mentioned conditions. A large siderostat, constructed by Eichens after Foucault's design, was completed in 1868—the year of Foucault's death. It remained at the Paris Observatory, where it was subsequently employed by Deslandres for solar photography. The largest refracting telescope yet made, viz., that constructed by Gautier for the Paris exhibition of 1900, was arranged on this plan (type F), the stars' rays being reflected along the horizontal axis of a telescope provided with visual and with photographic object-glasses of 49-in. diameter and nearly 200-ft. focal length. Up to 1908 neither the optical qualities of the images given by the object-glasses and reflecting plane nor the practical working of the instrument, have, so far as we know, been submitted to any severe test. It is, however, certain that the Foucault siderostat is not capable, in practice, of maintaining the reflected image in a constant direction with perfect uniformity on account of the sliding action on the arm that regulates the motion of the mirror; such an action must, more or less, take place by jerks. There are farther inconveniences in the use of such a telescope, viz., that the image undergoes a diurnal rotation about the axis of the horizontal telescope, so that, unless the sensitive plate is also rotated by clockwork, it is impossible to obtain sharp photographs with any but instantaneous exposures. In the spectroscopic observation of a single star with a slit-spectroscope, this rotation of the image presents no inconvenience, and the irregular action of a siderostat on Foucault's plan might be overcome by the following arrangement:—

A B (fig. 23) is a polar axis, like that of an equatorial telescope, rotating in twenty-four hours by clockwork. Its lower extremity terminates in a fork on which is mounted a mirror C D, capable of turning about A on an axis at right angles to A B, the plane of the mirror being parallel to this latter axis. The mirror C D is set at such an angle as to reflect rays from the star S in the direction of the polar axis to the mirror R and thence to the horizontal telescope T.

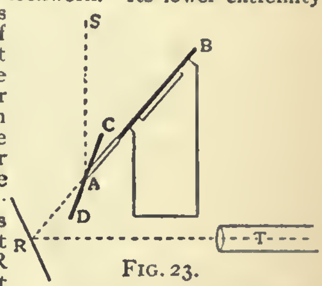

FIG. 23.

The mirrors of Lindemann's equatorial coudé reflecting light downwards upon the mirror R would furnish an ideal siderostat for stellar spectroscopy in conjunction with a fixed horizontal telescope.

Coelostat.—If a mirror is mounted on a truly adjusted polar axis, the plane of the mirror being parallel to that axis, the normal to that mirror will always be directed to some point on the celestial equator through whatever angle the axis is turned. Also, if the axis is made to revolve at half the apparent diurnal motion of the stars, the image of the celestial sphere, viewed by reflection from such a moving mirror, will appear at rest at every point—hence the name *coelostat* applied to the apparatus. Thus, any fixed telescope directed towards the mirror of a properly adjusted coelostat in motion will show all the stars in the field of view at rest; or, by rotating the polar axis independently of the clockwork, the observer can pass in review all the stars visible above the horizon whose declinations come within the limits of his original field of view. Therefore, to observe stars of a different declination it will be necessary either to shift the direction of the fixed telescope, keeping its axis still pointed to the coelostat mirror, or to employ a second mirror to reflect the rays from the coelostat mirror along the axis of a fixed telescope. In the latter case it will be necessary to provide means to mount the coelostat on a carriage by which it can be moved east and west without changing the altitude or azimuth of its polar axis, and also to shift the second mirror so that it may receive all the light from the reflected beam. Besides these complications there is another drawback to the use of the coelostat for general astronomical work, viz., the obliquity of the angle of reflection, which can never be less than that of the declination of the star, and may be greater to any extent. For these reasons the coelostat is never likely to be largely employed in general astronomical work, but it is admirably adapted for spectroscopic and bolometric observations of the sun, and for use in eclipse expeditions. For details of the coelostat applied to the Snow telescope—the most perfect installation for spectroheliograph and bolometer work yet erected—see *The Study of Stellar Evolution* by Prof. G. E. Hale, p. 131.

The Zenith Telescope

The zenith telescope is an instrument generally employed to measure the difference between two nearly equal and opposite zenith distances. Its original use was the determination of geographical latitudes in the field work of geodetic operations; more recently it has been extensively employed for the determination of variation of latitude, at fixed stations, under the auspices of the International Geodetic Bureau, and for the astronomical determination of the constant of aberration. The instrument is shown in its most recent form in fig. 24. A is a sleeve that revolves very freely and without shake on a vertical steel cone. This cone is mounted on a circular base *b* which rests on three levelling screws, two of which are visible in the figure. The sleeve carries a cross-piece on its upper extremity to which the bearings of the horizontal axis *c* are attached. A reversible level *d* rests on the accurately turned pivots of this axis. The telescope is attached to one end of this axis and a counterpoise *e* to the other. The long arm *f* serves to clamp the telescope in zenith distance and to communicate slow motion in zenith distance when so clamped. On the side of the telescope opposite to the horizontal axis is attached a graduated circle *g*, and, turning concentrically with this circle, is a framework *h*, to which the readers and verniers of the circle are fixed. This frame carries two very sensitive levels, *k* and *l*, and the whole frame can be clamped to the circle *g* by means of the clamping screw *m*.

The object-glass of the telescope is, of course, attached by its cell to the upper end of the telescope tube. Within the focus of the

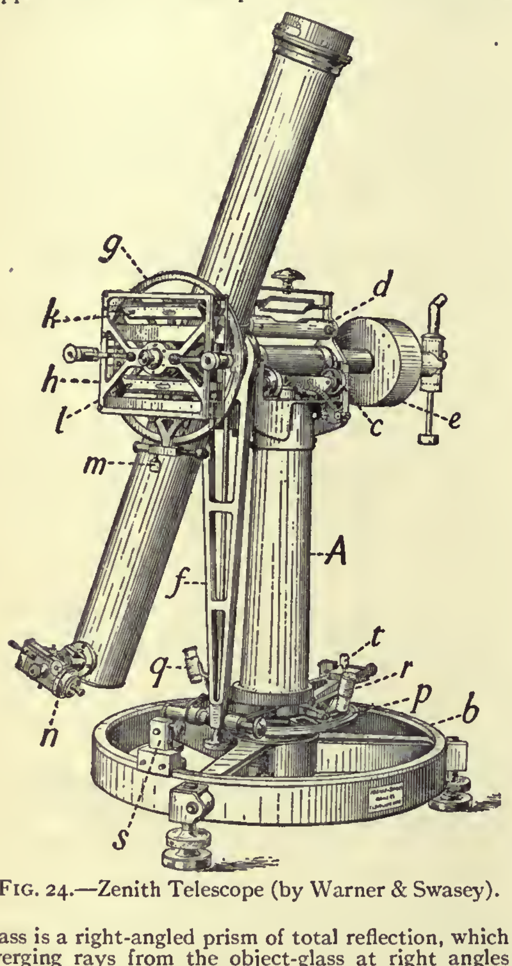

Fig. 24.—Zenith Telescope (by Warner & Swasey).

object-glass is a right-angled prism of total reflection, which diverts the converging rays from the object-glass at right angles to the axis of the telescope, and permits the observing micrometer *n* to be mounted in the very convenient position shown in the figure. A small graduated circle *p* concentric with A is attached to the circular base *b* and read by the microscopes *q r*, attached to *a*. The instrument is thus a theodolite, although, compared with its other dimensions, feeble as an apparatus for the measurement of absolute altitudes and azimuths, although capable of determining these co-ordinates with considerable precision.

In practice the vertical circle is adjusted once for all, so that when the levels *k* and *l* are in the centre of their run, the verniers read true zenith distances. When the instrument has been set up and levelled (either with aid of the cross level *d*, or the levels *k* and *l*), the reading of the circle *p* for the meridional position of the telescope is determined either by the method of transits in the meridian (see Transit Circle), or by the observation of the azimuth of a known star at a known hour angle. This done, the stops *s* and *t* are clamped and adjusted so that when arm *r* comes in contact with the screw of stop *t* the telescope will point due north, and when in contact with *s*, it will point due south, or vice versa. A pair of stars of known declination are selected such that their zenith distances, when on the meridian, are nearly equal and opposite, and whose right ascensions differ by five or ten minutes of time. Assuming, for example, that the northern star has the smaller right ascension, the instrument is first, with the aid of the stop, placed in the meridian towards the north; the verniers of the graduated circle *g* are set to read to the reading $\phi-\frac{1}{2}(\delta_n+\delta_s)$ where ϕ is the approximate latitude of the place and δ_n, δ_s the declinations of the northern and southern star respectively; then the level frame *h* is turned till the levels *k* and *l* are in the middle of their run, and there clamped by the screw *m*, aided in the final adjustment by the adjoining slow motion screw shown in the figure. The telescope is now turned on the horizontal axis till the levels read near the centres of these scales and the telescope is clamped to the arm *f*. When the star enters the field of view its image is approximately bisected by the spider web of the micrometer *n*, the exact bisection being completed in the immediate neighbourhood of the meridian. The readings of the levels *k* and *l* and the reading of the micrometer-drum are then entered, and the observation of the northern star is complete. Now the instrument is slowly turned towards the south, till the azimuth arm is gently brought into contact with the corresponding stop *s*, care being taken not to touch any part of the instrument except the azimuth arm itself. When the southern star enters the field the same process is repeated.

Suppose now, for the moment, that the readings of the levels *k* and *l* are identical in both observations, we have then, in the difference between the micrometer readings north and south, a measure of the difference of the two zenith distances expressed in terms of the micrometer screw; and, if the "value of one revolution of the micrometer screw" is known in seconds of arc we have for the resulting latitude

$$\phi=\tfrac{1}{2}\{(\zeta_n-\zeta_s)+(\delta_n+\delta_s)\},$$

where $\zeta_n-\zeta_s$ is the difference of the micrometer readings converted into arc—it being assumed that increased micrometer readings correspond with increased zenith distance of the star.

If between the north and south observation there is a change in the level readings of the levels *k* and *l*, this indicates a change in the zenith distance of the axis of the telescope. By directing the telescope to a distant object, or to the intersection of the webs of a fixed collimating telescope (see Transit Circle), it is easy to measure the effect of a small change of zenith distance of the axis of the telescope in terms both of the level and of the micrometer screw, and thus, *if the levels are perfectly sensitive and uniform in curvature and graduation*, to determine the value of one division of each level in terms of the micrometer screw. The value of "one revolution of the screw in seconds of arc" can be determined either by observing at transit the difference of zenith distance of two stars of known declination in terms of the micrometer screw, the instrument remaining at rest between their transits; or by measuring at known instants in terms of the screw, the change of zenith distance of a standard star of small polar distance near the time of its greatest elongation.

The reason why two levels are employed is that sometimes crystals are formed by the decomposition of the glass which cause the bubble to stick at different points and so give false readings. Two levels are hardly likely to have such causes of error arise at exactly corresponding points in their run, and thus two levels furnish an independent control the one on the other. Also it is impossible to make levels that are in every respect perfect, nor even to determine these errors for different lengths of bubble and at different readings with the highest precision. The mean of two levels therefore adds to the accuracy of the result.

Attempts have been made to overcome the difficulties connected with levels by adopting the principle of Kater's floating collimator (*Phil. Trans.*, 1825 and 1828). On this principle the use of the level is abolished, the telescope is mounted on a metallic float, and it is assumed that, in course of the rotation of this float, the zenith distance of the axis of the telescope will remain undisturbed, that is, of course, after the undulations, induced by the disturbance of the mercury, have ceased.

S. C. Chandler in 1884 constructed an equal altitude instrument on this principle, which he called the almucantar, and he found that after disturbance the telescope recovered its original zenith distance within $\frac{1}{20}$ of a second of arc. R. A. Sampson at Durham (*Monthly Notices R.A.S.* lx. 572) and H. A. Howe (*Ast. Jahrb.* xxi. 57) have had instruments constructed on the same general principle. It is, however, obviously impossible to apply a micrometer with advantage to such instruments, because to touch such an instrument, in order to turn a micrometer screw, would obviously set it into motion. The almucantar was therefore used only to observe the vertical transits of stars in different azimuths over fixed horizontal webs, without touching the telescope.

By the use of photography, however, it is possible to photograph the trail of a star as it transits the meridian when the telescope is directed towards the north, and another trail be similarly photographed when the telescope is directed towards the south. The interval between the true trails, measured at right angles to the direction of the trails, obviously corresponds to the difference of zenith distance of the two stars. This principle has been applied with great completeness and ingenuity of detail by Bryan Cookson to the construction of a "photographic floating zenith telescope," which he has erected at Cambridge (Eng.) and applied to an investigation of the change of latitude and a determination of the constant of refraction. A description of the instrument, and some preliminary results obtained by it, is given by him (*Monthly Notices R.A.S.*, lxi. 314). [D. Gi.]

TELESIA [mod. Telese], a town of the Samnites, 24 m. N.W. from Beneventum. It possesses remains of walls in *opus reticulatum*, of a total length of over a mile; two inscriptions of the Republican period record the erection of towers. The remains of baths (*Thermae Sabinianae*) and of an amphitheatre still exist: and the city was supplied with water by an aqueduct. There are sulphur springs in the vicinity, which may have supplied the baths.

TELESILLA, Greek poetess, a native of Argos, one of the so-called nine lyric muses. According to the traditional story, when Cleomenes, king of Sparta, invaded the land of the Argives in 510 B.C., and slew all the males capable of bearing arms, Telesilla, dressed in men's clothes, put herself at the head of the women and repelled an attack upon the city of Argos. To commemorate this exploit, a statue of the poetess, in the act of putting on a helmet, with books lying at her feet, was set up in the temple of Aphrodite at Argos. The festival *Hybristica* or *Endymatia*, in which men and women exchanged clothes, also celebrated the heroism of her female compatriots. Herodotus (vi. 76) does not refer to the intervention of Telesilla, but mentions an oracle which predicted that the female should conquer the male, whence the tradition itself may have been derived. Further, the statue seen by Pausanias may not have been intended for Telesilla; it would equally represent Aphrodite, in her character as wife of Ares and a warlike goddess (the books, however, seem out of place). The *Hybristica*, again, was most probably a religious festival connected with the worship of some androgynous divinity. Of Telesilla's poems only two lines remain, quoted by the grammarian Hephaestion, apparently from a Parthenion, or song for a chorus of maidens.

See Pausanias ii. 20, 8; Plutarch, *De Virtut. Mulierum*, 8; Clement of Alexandria, *Stromata*, iv. 19, p. 522; Bergk, *Poetae Lyrici Graeci*, iii.; and especially Macan, *Herodotus iv.–vi.*, i. 336 foll. and notes.

TELESIO, BERNARDINO (1509–1588), Italian philosopher and natural scientist, was born of noble parentage at Cosenza near Naples in 1509. He was educated at Milan by his uncle, Antonio, himself a scholar and a poet of eminence, and afterwards at Rome and Padua. His studies included all the wide range of subjects, classics, science and philosophy, which constituted the curriculum of the Renaissance savants. Thus equipped, he began his attack upon the medieval Aristotelianism which then flourished in Padua and Bologna. Resigning to his brother the archbishopric of Cosenza, offered to him by Pope Pius IV., he began to lecture at Naples and finally founded the academy of Cosenza. In 1563, or perhaps two years later, appeared his great work *De Rerum Natura*, which was followed by a large number of scientific and philosophical works of subsidiary importance. The heterodox views which he maintained aroused the anger of the Church on behalf of its cherished Aristotelianism, and a short time after his death his books were placed on the Index.

Telesio was the head of the great South Italian movement which protested against the accepted authority of abstract reason, and sowed the seeds from which sprang the scientific methods of Campanella and Bruno, of Bacon and Descartes, with their widely divergent results. He, therefore, abandoned the purely intellectual sphere and proposed an inquiry into the data given by the senses, from which he held that all true knowledge really comes. Instead of postulating matter and form, he bases existence on matter and force. This force has two opposing elements: heat, which expands, and cold, which contracts. These two processes account for all the diverse forms and types of existence, while the mass on which the force operates remains the same. The harmony of the whole consists in this, that each separate thing develops in and for itself in accordance with its own nature while at the same time its motion benefits the rest. The obvious defects of this theory, (1) that the senses alone cannot apprehend matter itself, (2) that it is not clear how the multiplicity of phenomena could result from these two forces, and (3) that he adduced no evidence to substantiate the existence of these two forces, were pointed out at the time by his pupil, Patrizzi (see article on PATRIZZI, FRANCESCO). Moreover his theory of the cold earth at rest and the hot sun in motion was doomed to disproof at the hands of Copernicus. At the same time, the theory was sufficiently coherent to make a great impression on Italian thought. When Telesio went on to explain the relation of mind and matter, he was still more heterodox. Material forces are, by hypothesis, capable of feeling; matter also must have been from the first endowed with consciousness. For consciousness exists, and could not have been developed out of nothing. Again, the soul is influenced by material conditions; consequently the soul must have a material existence. He further held that all knowledge is sensation ("non ratione sed sensu") and that intelligence is, therefore, an agglomeration of isolated data, given by the senses. He does not, however, succeed in explaining how the senses alone can perceive difference and identity. At the end of his scheme, probably in deference to theological prejudices, he added an element which was utterly alien, namely, a higher impulse, a soul superimposed by God, in virtue of which we strive beyond the world of sense. The whole system of Telesio shows lacunae in argument, and ignorance of essential facts, but at the same time it is a forerunner of all subsequent empiricism, scientific and philosophical, and marks clearly the period of transition from authority and reason to experiment and individual responsibility. Beside the *De Rerum Natura*, he wrote *De Somno*, *De his quae in aere fiunt*, *De Mari*, *De Cometis et Circulo Lacteo*, *De usu respirationis*, &c.

TELESPHORUS, bishop of Rome from about 126 till about 137. St Irenaeus says that he suffered martyrdom.

TELFORD, THOMAS (1757–1834), British civil engineer, was the son of a shepherd, and was born at Westerkirk in Eskdale, Dumfriesshire, on the 9th of August 1757. From early childhood he was employed as a herd, occasionally attending the parish school of Westerkirk, where his quickness and diligence helped to make up for his lack of opportunity. On being apprenticed, at the age of fifteen, to a stonemason at Langholm, he found leisure not only to gain an acquaintance with Latin, French and German, but to gratify his literary tastes by a wide variety of reading. In his early manhood he was much given to the writing of verse: a poem of some length on Eskdale appeared in 1784 in the *Poetical Museum*, published at Hawick; under the signature of "Eskdale Tam" he contributed verses to Ruddiman's *Weekly Magazine;* and he addressed an epistle in rhyme to Burns, which was published in James Currie's *Life* of the poet. In 1780 Telford went to Edinburgh, where he was employed in the erection of houses in the "new" town, and occupied much of his spare time in learning architectural drawing. Proceeding to London two years later, he found employment in the erection of Somerset House. Having in 1784 superintended the erection of a house for the commissioner at Portsmouth dockyard, he next repaired the castle of Sir W. Pulteney, member for Shrewsbury, who conceived such a high opinion of his talents that he got him made surveyor of public works for the county of Salop. In 1793 he was appointed engineer of the Ellesmere canal, for which he built the Chirk and Pont-y-Cysyllte aqueducts, and this work established his reputation as a canal engineer. He was consulted in 1806 by the king of Sweden regarding the construction of the Göta Canal, and, his plans having been adopted, he visited the country in 1810 to superintend some of the more important excavations. In the early years of the 19th century the question of improving the communications in the Highlands of Scotland engaged the attention of the government, and Telford was commissioned to report on the matter. In consequence of his recommendations, he was appointed engineer for the Caledonian Canal, which was begun in 1804 and forms one of the largest but by no means the most useful of his undertakings, and also for the construction of 920 miles of roads, a great part through very difficult country. Of the numerous bridges built in this line of roads mention may be specially made of that across the Tay at Dunkeld. Subsequently he was employed on the improvement of the road between Carlisle and Glasgow, which was undertaken as a result of a parliamentary inquiry in 1814, and he was then entrusted with the execution of another scheme, of equal magnitude and importance with that in the Highlands of Scotland, for a system of roads through the more inaccessible parts of Wales, which involved the erection of the magnificent suspension bridge across the Menai Straits, begun in 1820, and the Conway Bridge, begun in 1822. While his fame rests chiefly on his road and canal engineering, and the erection of the numerous bridges and aqueducts which this involved, he also did good work in harbour construction. The fisheries and industries of Scotland benefited by the improvements he effected at many of the harbours on the east coast; he constructed the St Katherine's Docks, London (finished in 1828); and his last piece of professional work was a plan for the improvement of Dover harbour. Other achievements of his later years were the drainage of the north level of the eastern Fen district, an area of 48,000 acres, and erection of the Dean Bridge, Edinburgh, and of the Broomielaw Bridge, Glasgow. He died on the 2nd of September 1834 in London, and was buried in Westminster Abbey.

Telford was never married. For twenty-one years he lived at the Salopian coffee-house, afterwards the Ship Hotel, Charing Cross, whence he removed to 24 Abingdon Street. He was a fellow of the Royal Societies of London and of Edinburgh, and was annually elected president of the Institution of Civil Engineers from its foundation. He received the Swedish order of knighthood of Gustavus Vasa.

See Telford's *Memoirs*, written by himself and edited by John Rickman (1838); also Smiles's *Lives of the Engineers*.

TÉLIGNY, CHARLES DE (*c.* 1535–1572), French soldier and diplomat, belonged to a respected Huguenot family of Rouerque, and received an excellent training in letters and arms at the house of Coligny. He was employed on several peace missions; he represented the Protestants before the king, and was entrusted by Condé with the presentation of his terms to the queen-mother in 1567, and in the following year he assisted at the conference at Châlons and signed the peace of Longjumeau, which was destined to be of short duration. On the outbreak of war, he took part in the siege of Poitiers, directed an unsuccessful attack on Nantes, fought bravely under Coligny at Moncontour, and participated in the negotiations ending in the treaty of Saint-Germain (8th of August 1570). In 1571 he retired to La Rochelle and married Louise de Coligny, but was speedily recalled to Paris to serve on the bi-partisan commission of adjustment. Although he won the special favour of Charles IX., he was one of the first victims in the massacre of St Bartholomew's Day (24th of August 1572). His remains were taken to the Castle of Téligny in 1617, but eight years later were thrown into the river by the bishop of Castres.

TELL, WILLIAM. The story of William Tell's skill in shooting at and striking the apple which had been placed on the head of his little son by order of Gessler, the tyrannical Austrian bailiff of Uri, is so closely bound up with the legendary history of the origin of the Swiss Confederation that they must be considered together. Both appear first in the 15th century, probably as results of the war for the Toggenburg inheritance (1436–50); for the intense hatred of Austria, greatly increased by her support of the claims of Zürich, favoured the circulation of stories which assumed that Swiss freedom was of immemorial antiquity, while, as the war was largely a struggle between the civic and rural elements in the Confederation, the notion that the (rural) Schwyzers were of Scandinavian descent at once separated them from and raised them above the German inhabitants of the towns.

The Tell story is first found in a ballad the first nine stanzas of which (containing the story) were certainly written before 1474. There is no mention made of the names of the bailiff or of his master, or of the hat placed on a pole. Tell is called "the first Confederate," and his feat is treated as the real and only reason why the Confederation was formed and the tyrants driven out of the land. It is probably to this ballad that Melchior Russ of Lucerne (who began his *Chronicle* in 1482) refers when, in his account (from Justinger) of the evil deeds of the bailiffs in the Forest districts, he excuses himself from giving the story. He goes on to narrate how Tell, irritated by his treatment, stirred up his friends against the governor, who seized and bound him and was conveying him by boat to his castle on the lake of Lucerne, when a storm arose, and Tell, by reason of his great bodily strength, was, after being unbound, given charge of the rudder on his promise to bring the boat safely to land. He steers it towards a shelf of rock, called in Russ's time Tell's Platte, springs on shore, shoots the bailiff dead with his crossbow, and goes back to Uri, where he stirs up the great strife which ended in the battle of Morgarten. In these two accounts, which form the basis of the Uri version of the origin of the Confederation, it is Tell and Tell only who is the actor and the leader. We first hear of the cruelties of Austrian bailiffs in the Forest districts in the *Bernese Chronicle* of Conrad Justinger (1420). No names or details are given, and the dates are different in the two recensions of the *Chronicle* as "olden days before Bern was founded" (*i.e.* before 1191) and 1260. Several details, but only one name, are added in the *De Nobilitate et Rusticitate Dialogus* (cap. 33) of Felix Hemmerli, a canon of Zürich, who wrote it after 1451 and before 1454; in this last year he was imprisoned by the Schwyzers, whom he had repeatedly insulted and attacked in his books. According to him the men of Schwyz and of Unterwalden were the first to rise, those of Uri following suit much later But neither Justinger nor Hemmerli makes any allusion to Tell or his feat.

The Tell story and the "atrocities" story are first found combined in a MS. known as the *White Book of Sarnen*. They are contained in a short chronicle written between 1467 and 1476, probably about 1470, and based on oral tradition. Many details are given of the oppressions of the bailiffs: we hear of Gessler, of the meeting of Stoupacher of Schwyz, Fürst of Uri, and a man of Nidwalden at the Rütli,- -in fact, the usual version of the legend. To give an instance of tyranny in Uri, the author tells us the story of the refusal of "der Thäll" to do reverence to the hat placed on a pole, of his feat of skill, and of his shooting the bailiff, Gessler, from behind a bush in the "hollow way" near Küssnacht. Tell is represented as being one of those who swore at the Rütli to drive out the oppressors; but the narrative of his doings is merely one incident in the general movement which began quite independently of him. The chronology is very confused, but the events are placed after Rudolf's election to the empire in 1273. This is the only account in which Tell is called "der Thäll," which name he himself explains by saying, "If I were sharp (*witzig*) I should be called something else and not der Tall," *i.e.* the simpleton or slow-witted man. (It is worthy of notice that the same meaning is attributed to the name of Tokko, the hero of a similar legend in Gheysmer's abridgment of the *Historia Danica* of Saxo Grammaticus, which may, somehow, have influenced the Swiss version.) The only other known instances of the Uri version of the legend relating to the origin of the Confederation are the Latin hexameters of Glareanus (1515), in which Tell is compared to Brutus as "assertor patriae, vindex ultorque tyrannum," and the *Urnerspiel* (composed in 1511–12), a play acted in Uri, in which Russ's version is followed, though the bailiff, who is unnamed, but announces that he has been sent by Albert of Austria, is slain in the "hollow way." Tell is the chief of the Rütli leaguers, and it is his deed which is the immediate occasion of the rising against the oppressors, which is dated in 1296. Mutius (1540) is the latest writer who, in his description of the origin of the Confederation, does not mention Tell and his act. The two stories are now firmly bound together; the version contained in the *White Book* is the accepted one, though small additions in names and dates are often made.

The task of filling up gaps, smoothing away inconsistencies, rounding off the tale, was accomplished by Giles Tschudi (*q.v.*), whose recension was adopted, with a few alterations, by Johannes von Müller in his *History of the Confederation* (1780). In the final recension of Tschudi's *Chronicle* (1734–36), which, however, differs in many particulars from the original draft still preserved at Zürich, we are told how Albert of Austria, with the view of depriving the Forest lands of their ancient freedom, sent bailiffs (among them Gessler) to Uri and Schwyz, who committed many tyrannical acts, so that finally on

8th November 1307, at the Rütli, Werner von Stauffacher of Schwyz, Walter Fürst of Uri, Arnold von Melchthal in Unterwalden, each with ten companions, among whom was William Tell, resolved on a rising to expel the oppressors, which was fixed for New Year's Day 1308. A few days later (November 18) the Tell incident takes place (described according to the *White Book* version), and on the appointed date the general rising. Tschudi thus finally settled the date, which had before varied from 1260 to 1334. He utterly distorts the real historical relations of the Three Lands, though he brings in many real historical names, their owners being made to perform historically impossible acts, and introduces many small additions and corrections into the story as he had received it. In particular, while in his first draft he speaks of the bailiff as Gryssler—the usual name up to his time, except in the *White Book* and in Stumpff's *Chronicle* of 1548—in his final recension he calls him Gessler, knowing that this was a real name. Later writers added a few more particulars,—that Tell lived at Bürglen and fought at Morgarten (1598), that he was the son-in-law of Fürst and had two sons (early 18th century), &c. Johannes von Müller (1780) gave a vivid description of the oath at the Rütli by the three (Tell not being counted in), and threw Tschudi's version into a literary form, adding one or two names and adopting that of Hermann for Gessler, calling him of "Bruneck." Schiller's play (1804) gave the tale a world-wide renown.

The story was, on the ground of want of evidence, regarded as suspicious by Guilliman in a private letter of 1607, and doubts were expressed by the brothers Iselin (1727 and 1754) and by Voltaire (1754); but it was not till 1760 that the legend was definitely attacked, on the ground of its similarity to the story of Tokko (see below), in an anonymous pamphlet by Freudenberger, a Bernese pastor. This caused great stir; it was publicly burnt by order of the government of Uri, and many more or less forged proofs and documents were produced in favour of Tell. The researches of J. E. Kopp (*Urkunden zur Geschichte d. eidgenössischen Bünde*, 2 parts, 1835 and 1851, and *Geschichte der eidgenössischen Bünde*, vol. ii., 1847), first cleared up the real early history of the league, and overthrew the legends of the *White Book* and Tschudi. Since then many writers have worked in the same direction. Vischer (1867) has carefully traced out the successive steps in the growth of the legend, and Rochholz (1877) has worked out the real history of Gessler as shown in authentic documents. The general result has been to show that a mythological marksman and an impossible bailiff bearing the name of a real family have been joined with confused and distorted reminiscences of the events of 1245–47, in which the names of many real persons have been inserted and many unauthenticated acts attributed to them. Th. von Liebenau has, however, shown (in an article reprinted from the *Katholische Schweizerblätter* in the *Bollettino Storico della Svizzera Italiana* for 1899) that in 1283 the Emperor Rudolf of Habsburg gave the right of receiving the tolls for escort over the St Gotthard Pass to his sons, the dukes of Austria. The levying of these tolls gave rise to various disputes between the men of Uri and the bailiffs of the dukes of Austria, and by 1319 (if not already in 1309) the claim to levy them was silently given up. These facts show (what could not hitherto be proved) that at the time when legend places the rising of Uri, Tell exploit, &c., the dukes of Austria really had disputes with Uri.

The story of the skilful marksman who succeeds in striking some small object placed on the head of a man or child is very widely spread: we find it in Denmark (Tokko), Norway (two versions), Iceland, Holstein, on the Rhine, and in England (William of Cloudesley). How it came to be localized in Uri we do not know; possibly, through the story of the Scandinavian colonization of Schwyz, the tale was fitted to some real local hero.

The alleged proofs of the existence of a real William Tell in Uri in the 14th century break down hopelessly. (1) The entries in the parish registers are forged. (2) As to the Tell chapels—(*a*) that in the "hollow way" near Küssnacht was not known to Melchior Russ and is first mentioned by Tschudi (1572). (*b*) That on Tell's Platte is first mentioned in 1504. The document which alleges that this chapel was built by order of a "landsgemeinde" held in 1388, at which 114 men were present who had been personally acquainted with Tell, was never heard of till 1759. The procession in boats to the place where the chapel stands may be very old, but is not connected with Tell till about 1582. (*c*) The chapel at Bürglen is known to have been founded in 1582. Other documents and statements in support of the Tell story have even less claim to credit. It has been pointed out above that with two exceptions the bailiff is always called Gryssler or Grissler, and it was Tschudi who popularized the name of Gessler, though Grissler occurs as late as 1765. Now Gessler is the name of a real family, the history of which from 1250 to 1513 has been worked out by Rochholz, who shows in detail that no member ever played the part attributed to the bailiff in the legend, or could have done so, and that the Gesslers could not have owned or dwelt at the castle of Küssnacht; nor could they have been called Von Bruneck.

In the *Urnerspiel* the name of the bailiff's servant who guarded the hat on the pole is given as Heintz Vögely, and we know that Friedrich Vögeli was the name of one of the chief military officers of Peter von Hagenbach, who from 1469 to 1474 administered for Charles the Bold, duke of Burgundy, the lands (Alsace, &c.) pledged to him by Sigismund of Habsburg. Now Hagenbach is known to have committed many cruelties like those attributed to the bailiffs in the legend, and it has been plausibly conjectured that his case has really given rise to these stories, especially when we find that the Confederates had a hand in his capture and execution, that in a document of 1358 Hagenbachs and Gesslers appear side by side as witnesses, and that the Hagenbachs had frequent transactions with the Habsburgs and their vassals.

In general see two excellent works by Franz Heinemann, *Tell-Iconographie*, Lucerne, 1902 (reproductions, with text, of the chief representations of Tell in art from 1507 onwards), and *Tell-Bibliographie* (including that of Schiller's play), published in 1908 at Bern.

Among the vast number of books and pamphlets on the Tell story, the two most to be recommended are W. Vischer, *Die Sage von der Befreiung der Waldstätte* (Leipzig, 1867), and E. L. Rochholz, *Tell und Gessler*, with a volume of documents 1250–1513 (Heilbronn, 1877). Convenient summaries of the controversy will be found in any modern book on Swiss history, and more particularly in G. von Wyss, *Über d. Gesch. d. drei Länder—Uri, Schwyz, u. Unterwalden —in den Jahren* 1212–1315 (Zürich, 1858); Alf. Huber, *Die Waldstätte bis zur festen Begründung ihrer Eidgenossenschaft, mit einem Anhange über die geschichtliche Stellung des Wilh. Tell* (Innsbruck, 1861); Albert Rilliet, *Les Origines de la Confédération Suisse, histoire et légende* (Geneva, 2nd edition, 1869); and S. Baring-Gould, *Curious Myths of the Middle Ages*, ch. v. (new edition, London, 1884).

The setting up in 1895 in the market-place in Altdorf of a fine statue (by the Swiss sculptor Richard Kissling) of Tell and his son, and the opening in 1899 just outside Altdorf of a permanent theatre, wherein Schiller's play is to be represented every Sunday during the summer months, show that the popular belief in the Tell legend is still strong, despite its utter demolition at the hands of a succession of scientific Swiss historians during the 19th century. A. Gisler of Altdorf (in his book, *Die Tellfrage*, Bern, 1895) has also made an attempt to rehabilitate it from the purely historical point of view. He is well acquainted with all the researches that have been made, but tries to save Tell's refusal to do reverence to the hat, his leap from the boat in the lake, and his slaying of the bailiff in the "hollow way." To effect the rescue of these incidents, he boldly admits the forgeries in the registers, abandons all the traditional dates, throws over Tschudi's account, and regards the shooting by Tell of the apple from his son's head as an "ornamental addition" to the tale. Save a mention of the Tell chapel on "Tellsplatte" in 1504 (the first known before was that by Tschudi in 1572), and a proof that the pilgrimages to Bürglen and Steinen had nothing to do with "St Kümmerniss," as her images are preserved in the *parish churches* of those villages, whereas the pilgrims go to the *chapels* therein, he brings forward no new evidence. His book is a striking proof that the popular Tell legend cannot claim the support of authentic history, while his attempt to find room for the atrocities of the wicked bailiffs elsewhere than at Altdorf consists only in suggesting an intricate series of possibilities, none of which are supported by any positive evidence.

In his pamphlet *Die Sagen v. Tell u. Stauffacher* (Basel, 1899) August Bernoulli, and in his elaborate *Geschichte d. Schweiz. Politik* (vol. i. Frauenfeld, 1906) J. Schollenberger, have applied the same sort of method, but without attaining any greater degree of historical success. (W. A. B. C.)

TELL EL AMARNA, the name now given to a collection of ruins and rock tombs in Upper Egypt near the east bank of the Nile, 58 m. by river below Assiut and 190 m. above Cairo. The ruins are those of Ekhaton (Akhet-Aton), a city built *c.* 1360 B.C. by Akhenaton (Amenophis IV.) as the new capital of his empire (in place of Thebes) when he abandoned the worship of Ammon and devoted himself to that of Aton, *i.e.* the sun (see EGYPT: *History*, § *Ancient*). Shortly after the death of Akhenaton the court returned to Thebes, and the city, after an existence of perhaps only twenty years—of fifty years at the utmost—was abandoned. Not having been inhabited since, the lines of the streets and the ground-plans of many buildings can still be traced. The chief ruins are those of the royal palace and of the House of the Rolls; there are scanty remains of the great temple. In the palace are four pavements of painted stucco work in fair preservation. They were discovered in 1891–92 by Prof. Flinders Petrie (see his *Tell el Amarna*, 1894). In the Rolls House were discovered in 1887 by the fellahin some 300 clay tablets inscribed with cuneiform characters. They are letters and state documents addressed to Amenophis IV. and his father, from the kings of Babylon, Assyria, &c., and from the Egyptian governors in Syria and neighbouring districts. The greater part of them were purchased for the Berlin Museum, but a large number were secured for the British Museum. Their contents proved invaluable for the reconstruction of the history, social and political, of Egypt and Western Asia during that period.

Hewn out of the sides of the hills which close in on the east the plain on which Ekhaton stood are two groups of tombs; one group lies 1½ m. N.E., and the other 3 m. S. of the city. The tombs, all of which belong to the time of Akhenaton, are full of interesting scenes in the peculiar style of the period, accompanied by hymns to the sun god. The most important tomb is, perhaps, that of Meri-Ra, high priest of the sun, which has a façade nearly 100 ft. long and two large chambers. On one of the walls of the main chamber is depicted the scene, now well known, in which a blind choir of harpists and singers celebrate the arrival of the court at the temple. In the early centuries of Moslem rule in Egypt the northern tombs were inhabited by Copts, one tomb, that of Pa-Nehesi, being turned into a church. In a ravine opening into the plain between the north and south tombs, and some seven miles from the city, is a tomb supposed to be that of Akhenaton.

The tombs and the great stelae sculptured on the cliffs which mark the bounds of the city of Akhet-Aton have been the object of special study by N. de G. Davies on behalf of the Archaeological Survey of Egypt. The results, with numerous plates and plans, are embodied in a series of memoirs, *Rock Tombs of El Amarna* (six parts, 1903–8).

For the tablets see *Tell el Amarna Tablets in the British Museum* (1892); C. Bezold, *Oriental Diplomacy; the transliterated text of the Cuneiform Despatches discovered at Tell el Amarna* (1893); *The Tel el Amarna Letters* (English translation by M. Winckler, Berlin, 1896); J. A. Knudtzon, *Die El-Amarna Tafeln* (Leipzig, 1907–9); W. M. F. Petrie, *Syria and Egypt from the Tell el Amarna Letters* (1898).

TELLER, WILHELM ABRAHAM (1734–1804), German Protestant divine, was born at Leipzig on the 9th of January 1734. His father, Romanus Teller (1703–1750), was a pastor at Leipzig, and afterwards became professor of theology in the university. He edited the earlier volumes of a *Bibelwerk* (19 vols., 1749–70) which was designed as an adaptation for German readers of the exegetical works of Andrew Willet, Henry Ainsworth, Symon Patrick, Matthew Poole, Matthew Henry and others. Wilhelm Abraham studied philosophy and theology in the university of his native town. Amongst the men whose influence mainly determined his theological position and line of work was J. A. Ernesti. Teller's writings present rationalism in its course of development from biblical supernaturalism to the borders of deistical naturalism. His first learned production was a Latin translation of Benjamin Kennicott's *Disserlation on the State of the Printed Hebrew Text of the Old Testament* (1756), which was followed the next year by an essay in which he expounded his own critical principles. In 1761 he was appointed pastor, professor of theology and general superintendent in the university of Helmstedt. Here he pursued his exegetical, theological and historical researches, the results of which appeared in his *Lehrbuch des christlichen Glaubens* (1764). This work caused some commotion, as much by the novelty of its method as by the heterodoxy of its matter, and more by its omissions than by its positive teaching, though everywhere the author seeks to put theological doctrines in a decidedly modern form. In 1767 Teller, whose attitude had made his position at Helmstedt intolerable, was glad to accept an invitation from the Prussian minister for ecclesiastical affairs to the post of provost of Kölln, with a seat in the supreme consistory of Berlin. Here he found himself in the company of the rationalistic theologians of Prussia—F. S. G. Sack (1738–1817), Johann Joachim Spalding (1714–1804) and others —and became one of the leaders of the rationalistic party, and one of the chief contributors to C. F. Nicolai's *Allgemeine Deutsche Bibliothek*. Teller was not long in making use of his freer position in Berlin. In 1772 appeared the most popular of his books, *Wörterbuch des Neuen Testamentes zur Erklärung der christlichen Lehre* (6th ed., 1805). The object of this work was to recast the language and ideas of the New Testament and give them the form of 18th-century illuminism. The author maintains that the Graeco-Hebraic expressions must not be interpreted literally, but explained in terms intelligible to the modern mind. By this lexicon Teller had put himself amongst the most advanced rationalists, and his opponents charged him with the design of overthrowing positive Christianity altogether. In 1786 the author became a member of the Berlin Academy of Sciences. The "Wöllner edict" of July 9, 1788, for the enforcement of Lutheran orthodoxy, and Teller's manly action, as member of the consistorial council, in defiance of it (cf. his *Wohlgemeinte Erinnerungen*, 1788), led the Prussian government to pass upon him the sentence of suspension for three months, with forfeiture of his stipend. He was not, however, to be moved by such means, and (1792) issued his work *Die Religion der Vollkommeneren*, an exposition of his theological position, in which he advocated at length the idea, subsequently often urged, of "the perfectibility of Christianity,"—that is, of the ultimate transformation of Christianity into a scheme of simple morality, with a complete rejection of all specifically Christian ideas and methods. This book represents the culminating point of German illuminism, and is separated by a long process of development from the author's *Lehrbuch*. In the same year he published his *Anleitung zur Religion überhaupt und zum Allgemeinen des Christenthums besonders; für die Jugend höherer und gebildeler Stände aller Religionsparteien*. Teller died on the 9th of December 1804. Besides his contributions to the *Allgemeine Deutsche Bibliothek*, he edited a popular and practically useful *Magazin für Prediger* (1792–1801).

TELLICHERRY, a seaport of British India, in the Malabar district of Madras, between Cannanore and the French settlement of Mahe. Pop. (1901) 27,883. It is a healthy and picturesque town, built upon a group of wooded hills running down to the sea, and is protected by a natural breakwater of rock. The town with its suburbs occupies about 5 sq. m., and was at one time defended by a strong mud wall. The old fort still stands to the north of the town. The East India Company established a factory here in 1683 for the pepper and cardamom trade. For two years (1780–82) the town withstood a siege by Hyder's general, and in the subsequent wars with Mysore Tellicherry was the base of operations for the ascent of the Ghats from the west coast. The town is a busy centre of export trade in coffee, coco-nut produce, spices and sandal-wood. The Basel Protestant mission has a station here. The municipality manages the Brennen college founded in 1862.

TELLURIUM [Symbol Te, atomic weight 127·5 (O=16)], a chemical element, found to a certain extent in nature in the uncombined condition, but chiefly in combination with other metals in the form of tellurides, such, for example, as sylvanite, black tellurium, and tetradymite. Small quantities are occasionally met with in iron pyrites, and hence tellurium is found with selenium in the flue dust, or chamber deposits of sulphuric acid works. Tellurium was first recognized as a distinct element in 1798 by M. H. Klaproth. It may be obtained by heating tellurium bismuth with sodium carbonate, lixiviating the fused mass with water, filtering, and exposing the filtrate to air, when the tellurium is gradually precipitated as a grey powder (J. J. Berzelius). J. Farbaky (*Zeit. angew. Chem.*, 1897, p. 11) extracts the element from black tellurium as follows:—The ore is boiled with concentrated sulphuric acid, the solution diluted, hydrochloric acid added and the tellurium (together with selenium) precipitated by sulphur dioxide and the process repeated when a purer tellurium is obtained. B. Brauner (*Monats.*, 1889, 10, p. 414) recommends the following method for the purification. The crude element is treated with aqua regia and then evaporated with an excess of hydrochloric acid, the solution diluted and the tellurium precipitated by a current of sulphur dioxide. The precipitated tellurium is then fused with potassium cyanide, the melt extracted with water and the element precipitated by drawing a current of air through the solution and finally distilled in a current of hydrogen.

Tellurium is a brittle silvery-white element of specific gravity 6·27. It melts at 452° C. and boils at 478° C. (F. Krafft, *Ber.*, 1903, 36, p. 4344). When heated in a current of hydrogen it sublimes in the form of brilliant prismatic crystals. An amorphous form is obtained when tellurium is precipitated from its solutions by sulphur dioxide, this variety having a specific gravity 6·015. When heated in air, tellurium burns, forming the dioxide TeO_2. The element is insoluble in water, but dissolves in concentrated sulphuric acid forming a deep red solution.

Like sulphur and selenium, tellurium combines directly with hydrogen to form *telluretted hydrogen*, TeH_2, an extremely objectionable smelling and highly poisonous gas, which was first prepared by Sir H. Davy in 1810. It is best obtained by decomposing metallic tellurides with mineral acids. It is soluble in water, the solution gradually decomposing with deposition of tellurium; it also decomposes on exposure to light. It burns, and also, like sulphuretted hydrogen, precipitates many metals from solutions of their salts. It may be liquefied, the liquid boiling at 0° C., and on further cooling, it solidifies, the solid melting at −48° C. Many tellurides of metals have been examined by C. A. Tibbals (*Jour. Amer. Chem. Soc.*, 1909, 31, p. 902) who obtained the sodium and potassium tellurides by the direct union of their component elements and others from these by precipitation. The tellurides of the alkali metals immediately decompose on exposure to air, with liberation of tellurium. Two chlorides are known, the *dichloride*, $TeCl_2$, and the *tetrachloride*, $TeCl_4$. They are both obtained by passing chlorine over tellurium, the product being separated by distillation (the tetrachloride is the less volatile). The dichloride is an amorphous, readily fusible, almost black solid. It is decomposed by water with formation of tellurium and tellurous acid: $2TeCl_2+3H_2O=Te+H_2TeO_3+4HCl$. The tetrachloride is a white crystalline solid which is formed by the action of chlorine on the dichloride or by sulphur chloride on the element. It melts at 224° C. and is exceedingly hygroscopic. Water decomposes it with formation of tellurous acid and other products. It combines directly with sulphur trioxide to form a complex of composition $TeCl_4 \cdot 2SO_3$. The tetrabromide similarly gives $TeOBr_2 \cdot 2SO_3$ (W. Prandtl, *Zeit. anorg. Chem.*, 1909, 62, p. 237). Iodides are also known.

Two oxides of the element are definitely known, viz., the *dioxide*, TeO_2, and the *trioxide*, TeO_3, whilst a *monoxide*, TeO, has also been described. The dioxide is formed by burning tellurium in air or by warming it with nitric acid. It is a colourless crystalline solid which readily fuses to a yellow liquid. The trioxide is an orange-coloured solid which is formed when telluric acid is strongly heated. *Tellurous acid*, H_2TeO_3, is obtained when the tetrachloride is decomposed by water, or on dissolving tellurium in nitric acid and pouring the solution into water. It is a colourless solid and behaves as a dibasic acid. The alkaline tellurites are soluble in water. It also gives rise to super-acid salts, such as $KHTeO_3 \cdot H_2TeO_3$; $K_2TeO_3 \cdot 3TeO_2$. *Telluric acid*, H_2TeO_4, is obtained in the form of its salts when tellurium is fused with potassium carbonate and nitre, or by the oxidizing action of chlorine on a tellurite in alkaline solution. The free acid may be obtained by decomposing the barium salt with sulphuric acid and concentrating the solution, when a crystalline mass of composition $H_2TeO_4 \cdot 2H_2O$ separates. It is also formed when the dioxide is oxidized by hydrogen peroxide in caustic potash solution (A. Gutbier, *Zeit. anorg. Chem.*, 1904, 40, p. 260), and perhaps best of all by oxidizing tellurium with a mixture of nitric and chromic acids. It crystallizes in prisms, which lose their water of crystallization at 160° C. The tellurates of the alkali metals are more or less soluble in water, those of the other metals being very sparingly or almost insoluble in water. Some tellurates exist in two forms, a colourless form soluble in water and acids, and a yellow form insoluble in water and acids. An oxychloride of tellurium has been described, but the investigations of V. Lenher (*Jour. Amer. Chem. Soc.*, 1909, 31, p. 20) seem to negative its existence.

A considerable amount of work has been done on determinations of the atomic weight of tellurium, the earlier results giving the value 128. According to its position in the periodic classification of the elements one would expect its atomic weight to be less than that of iodine, instead of approximately equal, and on this account many efforts have been made to isolate another element from tellurium compounds, but none have as yet been successful. Recent investigations of the atomic weight are due to G. Gallo (*Atti. R. Acad. Lincei*, 1905 (iv.), 14, pp. 1, 23, 104), who, by a determination of the electrochemical equivalent of the element, arrived at the value 127·61; A. Gutbier (*Ann.*, 1905, 342, p. 266) by reduction of the dioxide obtained 127·6; Marckwald, by determining the ratio of telluric acid to tellurium dioxide, obtained 126·85; H. B. Baker (*Jour. Chem. Soc.*, 1907, 91, p. 1849), by determining the ratio of tellurium dioxide to oxygen and by analysis of tellurium tetrabromide, obtained 127·60, and V. Lenher (*Jour. Amer. Chem. Soc.*, 1909, 31, p. 20), by heating the double salt, $TeBr_4 \cdot 2KBr$, first in chlorine and finally in a current of hydrochloric acid to convert it into potassium chloride, obtained the value 127·55. P. E. Browning and W. R. Flint (*Amer. J. Sci.*, 1909 (iv.), 28, p. 347) claim to have separated two substances (of atomic weights 126·49 and 128·85 respectively) from tellurium, by fractional precipitation of tellurium chloride with water, but in the opinion of H. B. Baker this would seem to point to the fact that the tellurium used was insufficiently purified, since his work showed that there was no difference between the first and last fractions (see *Chem. Soc. Ann. Rep.*, 1909, 6, p. 39). Marckwald (*Ber.*, 1903, 36, p. 2662) showed that the Joachimsthal pitchblende yields tellurium and a minute quantity of the strongly radioactive polonium which is precipitated by bismuth (see RADIOACTIVITY).

TELUGU, one of the five great Dravidian languages. The word is probably derived from Trilinga (=the three *lingas* of Siva), a name for the old Hindu kingdom of Andhra. It was at one time called by Europeans "Gentoo," from a Portuguese word meaning Gentile. The Telugu-speaking peoples are partly subjects of the nizam of Hyderabad and partly under British rule, beginning north of Madras city and extending N.W. to Bellary, where Telugu meets Kanarese, and N.E to near Orissa. They are taller and fairer than the Tamils, otherwise they are of typical Dravidian features. They are an enterprising people, good farmers and skilful seamen. They formed the greater part of the early Madras or "coast" army, whence sepoys even in Bengal were formerly called *telingas*. In 1901 the number of speakers of Telugu in all India was nearly twenty-one millions.

TEMBU (Ama-Tembu), popularly called Tambookies; one of the most powerful of Kaffir tribes, who have given their name to Tembuland, a division of Cape Colony which lies south-west of Griqualand East. In Kaffir genealogy they hold an honourable position, being traditionally descended from Tembu, elder brother of Xosa, from whom most "Kaffirs" claim descent (see KAFFIRS).

TEMENOS (Gr. *τέμενος*, *τέμνειν*, to cut), the Greek term in archaeology given to a piece of land which forms the enclosure of a temple, or sanctuary.

TEMESVÁR, the capital of the county of Temes, Hungary, 188 m. S.E. of Budapest by rail. Pop. (1900) 53,033. It lies on the navigable Béga canal and on the river Béga, and consists of the inner town, formerly strongly fortified, and of four outlying suburbs. Several parks have been laid out on the site of the broad glacis which formerly separated Temesvár from its suburbs, which are now united with it by broad avenues. Temesvár is the seat of a Roman Catholic and a Greek Orthodox bishop. Amongst its principal buildings are the Roman Catholic cathedral, built (1735–57) by Maria Theresa; the Greek Orthodox cathedral; a castle built by Hunyady Janos in 1442, now used as an arsenal; the town and county hall, the museum and large barracks. In the principal square rises a Gothic column, 40 ft. high, erected by the Emperor Francis Joseph in 1851 to commemorate the successful resistance of the town to the siege of 107 days laid by the Hungarian revolutionary army in 1849. Temesvár is the most important centre of commerce and industry of south Hungary, and carries on a brisk trade in grain, flour, spirits and horses. Its industrial establishments include factories for tobacco, cloth, matches, leather, artificial manure, besides breweries and distilleries.

Temesvár is an old town, and although destroyed by the Tatars in 1242, it was a populous place at the beginning of the 14th century, and was strongly fortified by King Charles Robert of Anjou, who resided here several years. The Hunyady family had also their residence here. In 1514 the peasant leader, Stephan Dozsa, was defeated by the Transylvanian voivod, John Zápolya, near Temesvár, captured and executed. Unsuccessfully besieged by the Turks in 1552, it was captured by them in the following year after a heroic resistance. It remained in their hands until 1716, when it was liberated by Prince Eugene of Savoy. New strong fortifications were erected, and the town grew steadily in importance, serving as the capital of the whole Banat. It endured another siege in 1849, when it resisted successfully the attacks of a Hungarian revolutionary army.

TEMPE, VALE OF, the ancient name (*i.e.* "cleft," from Gr. *τέμνειν*, to cut) of a narrow valley in N. Thessaly, through which the river Peneus (mod. Salambria) reaches the sea. The valley, which the Greeks were accustomed to associate with rural delights, is a chasm, cloven in the rocks, the fable tells us, by the trident of Poseidon, between Olympus and Ossa; but though it possesses every element of the sublime, yet its features are soft and beautiful, from the broad winding river, the luxuriant vegetation, and the glades that at intervals open out at the foot of the cliffs. It is about four miles and a half long, and towards the middle of the pass, where the rocks are highest, the precipices in the direction of Olympus fall so steeply as to bar the passage on that side; but those which descend from Ossa are the loftiest, for they rise in many places not less than 1500 ft. from the valley. Owing to the length and narrowness of the ravine, it was a position easily defended, but still it offered a practicable entrance to an invading force; a number of castles (of which the ruins still exist) were built at different times at the strongest points. Tempe was sacred to Apollo, to whom a temple was erected on the right bank. Every ninth year a sacred mission proceeded to the valley to pluck the laurel for the chaplets for the Pythian games. Owing to its widespread fame, the name Tempe was given also to the valley of the Velinus near Reate (Italy) and that of the Helorus in Sicily.

TEMPER (from Lat. *temperare*, to mingle or compound in due proportion, to qualify, rule, regulate, to be moderate, formed from *tempus*, time, fit or due season), to blend, modify, or qualify by mixing, to combine in due proportions, hence to restrain, calm. A specific application of the word is to the bringing of steel or other metal to a proper hardness and elasticity (see METAL and IRON AND STEEL). The word is also used as a substantive, especially in the transferred sense of disposition or frame of mind, generally with some qualifying epithet, but when used absolutely signifying a hasty, passionate temper, or display of such.

TEMPERA (the Italian term), or DISTEMPER, a method of painting in which solid pigments are employed, mixed with a water medium,[1] in which some kind of gum or gelatinous substance is dissolved to prevent the colours from scaling off. Tempera is also called in Italy *fresco a secco*, as distinguished from *fresco buono*, or true fresco, painted on freshly laid patches of stucco. Various media have been used for tempera work, such as the glutinous sap of the fig and other trees, various gums which are soluble in water, and size made by boiling down fish-bones, parchment and animals' hoofs. A mixture of egg and vinegar has also been found to make a good medium, especially when it is desirable to apply the colours in considerable body or *impasto*. For the nature and history of painting in tempera and fresco, see PAINTING.

TEMPERANCE. The word "temperance," which strictly means moderation, has acquired a particular meaning in connexion with intoxicating liquor, and it is here used in that limited sense. The "temperance question" is the equivalent in English of *l'alcoolisme* and *Alkoholismus* in French and German-speaking countries respectively; it embraces all the problems that arise in connexion with the use or abuse of alcoholic drink. This usage has arisen from the practice of societies formed for the purpose of suppressing or reducing the consumption of such liquors, and calling themselves Temperance Societies. Their activity is often spoken of as the Temperance Movement, though that term properly covers very much wider ground.

Historical.—Ever since man in some distant age first discovered that process of fermentation by which sugar is converted into alcohol and carbonic acid, and experienced the intoxicating effects of the liquor so produced, there has been, in a sense, a temperance question. The records of the ancient Oriental civilizations contain many references to it, and from very remote times efforts were made by priests, sages or law-givers in India, Persia, China, Palestine, Egypt, Greece and Carthage to combat the vice of drunkenness. But the evil appears never to have been so great or the object of so much attention in the ancient world as in Western countries and our own era. Two circumstances mainly differentiate the modern problem; one is the use of distilled waters or spirits as a beverage, and the other the climatic conditions prevailing in the more northern latitudes which are the home of Western civilization. The intoxicating drinks used by the ancients were wines obtained from grapes or other fruits and beers from various kinds of grain. These products were not confined to the East, but were known to the ancient civilizations of Mexico and Peru and even to primitive peoples who used the sugar-containing juices and other substances indigenous in their country. In the time of the Romans the barbarians in the north of Europe used fermented liquors made from honey (mead), barley (beer) and apples (cider) in place of grape-wine. All such drinks produce intoxication if taken in sufficient quantity; but their action is so much slower and less violent than that of distilled spirits that even their abuse did not give rise to any opposition that can properly be called a movement, and the distinction has repeatedly formed the basis of legislation in several countries down to this day. Extremists now place all alcohol-containing drinks under the same ban, but fermented liquors are still generally held to be comparatively innocuous; nor can any one deny that there is a difference. It is safe to say that if spirits had never been discovered the history of the question would have been entirely different. The distillation of essences from various substances seems to have been known to the ancients and to have been carried on by the Arabians in the dark ages; but potable spirits were not known until the 13th century. The distilled essence of wine or *aqua vitae* (brandy) is mentioned then as a new discovery by Arnoldus de Villa Nova, a chemist and physician, who regarded it, from the chemical or medical point of view, as a divine product. It probably came into use very gradually, but once the art of distillation had been mastered it was extended to other alcoholic substances in countries where wine was not grown. Malt, from which beer had been made from time immemorial, was naturally used for the

[1] Hence it used to be called "water-work"; see Shakespeare, *Hen. IV.*, part ii. act ii. sc. 1.

purpose, and then gin or Geneva spirits and whisky or usquebagh (Irish for "water of life") were added to grape brandy; then came corn brandy in the north and east of Europe, rum from sugar canes in the Indies, potato spirit, and eventually, as the process was perfected, rectified ethyl alcohol from almost anything containing sugar or starch.

The concentrated form of alcohol, thus evolved, for a long time carried with it the prestige of a divine essence from the middle ages when chemistry was a mysterious art allied to all sorts of superstitions. It had potent properties and was held to possess great virtue. This view is embodied in the name "water of life," and was at one time universally held; traces of it still linger among the very ignorant. Ardent spirit seemed particularly desirable to the habitants of the cold and damp regions of northern Europe, where the people took to it with avidity and imbibed it without restraint when it became cheap and accessible. That happened in England, as related in the article on LIQUOR LAWS, in the early part of the 18th century; and out of the frightful results which followed there eventually arose the modern Temperance Movement. The legislature had been busy with the liquor traffic for more than two centuries previously, but its task had been the repression of disorder; the thing was a nuisance and had to be checked in the interests of public order. It is significant that though drunkenness had been prevalent from the earliest times, the disorder which forced legislative control did not make its appearance until after the introduction of spirits; but they were not cheap enough to be generally accessible until the home manufacture of gin was encouraged towards the end of the 17th century, and consequently their use did not cause visible demoralization on a large scale until then. When, however, the spirit bars in London put up signboards, as related by Smollett, inviting people to be "drunk for one penny" and "dead drunk for 2d.," with "straw for nothing" on which to sleep off the effects, the full significance of unlimited indulgence in spirits became visible. Speaking in the House of Lords in 1743 Lord Lonsdale said:—

> "In every part of this great metropolis whoever shall pass along the streets will find wretchedness stretched upon the pavement, insensible and motionless, and only removed by the charity of passengers from the danger of being crushed by carriages or trampled by horses or strangled with filth in the common sewers. . . . These liquors not only infatuate the mind but poison the body; they not only fill our streets with madness and our prisons with criminals, but our hospitals with cripples. . . . Those women who riot in this poisonous debauchery are quickly disabled from bearing children, or produce children diseased from their birth."

The latter part of this quotation is particularly interesting because it proves the participation of women in public drunkenness at this period and shows that the physical ruin caused by excess and its national consequences were then for the first time recognized. It was the first step towards the inauguration of the Temperance Movement in the sense of a spontaneous and conscious effort on the part of the community as distinguished from the action of authority responsible for public decency. The need was only realized by degrees. Intemperance was one of many questions which we can now see were struggling into existence during the latter half of the 18th century, to become the subject matter of "social reform" in the 19th. Like the majority of them it was a question of bodily welfare, of health. A breach had been made in the unthinking traditional belief in the virtue of alcoholic liquor by the experiences referred to; and medical thought, as soon as it began to busy itself with health as distinguished from the treatment of disease, took the matter up. In 1804 Dr Trotter of Edinburgh published a book on the subject, which was an expansion of his academic thesis written in 1788; Dr Benjamin Rush of Philadelphia, a distinguished American physician and politician, who had studied in Edinburgh and London, wrote a striking paper on the same subject in the same year; and very soon after this the organized Temperance Movement was set on foot in the United States, where the habit of spirit-drinking had been transplanted from the British Islands.

Temperance Organization.—In 1808 a temperance society was founded at Saratoga in the state of New York, and in 1813 the Massachusetts Society for the Suppression of Intemperance made its appearance. These seem to have been the earliest organizations, though the device of a pledge of abstinence had been introduced in 1800. The movement made rapid progress mainly under the influence of the Churches. In 1826 the American Society for the Promotion of Temperance was founded in Boston, and by 1833 there were 6000 local societies in several states with more than a million members. The campaign was for the most part directed against the use of spirits only, and the proposal to include all alcoholic drinks in the pledge of abstinence, though adopted by a few societies, was rejected in 1833 by the American Society, but accepted in 1836 and retained ever since.

In Europe the earliest organizations were formed in Ireland. A temperance club is said to have been started at Skibbereen in 1818, and others followed; but it was in 1829 that the organized movement began to make effectual progress with the formation of the Ulster Temperance Society. By the end of that year there were twenty-five societies in Ireland and two or three in Scotland. In 1830 the movement spread to Yorkshire and Lancashire, and supported a newspaper called the *Temperance Societies' Record*, according to which there were then 127 societies with 23,000 paying members and 60,000 associated abstainers. In 1831 the British and Foreign Temperance Society was founded in London with the Bishop of London (Blomfield) for president and Archbishop Sumner for one of the vice-presidents. This important society, of which Queen Victoria became patron on her accession in 1837, came to an end in 1850, when the whole cause was under an eclipse. At the time it was formed temperance meant abstinence from spirits, as at first in the United States; but very soon afterwards the more drastic form of total abstinence began to be urged in the north of England and acquired the name of teetotalism from "tee-total," a local intensive for "total." It led to strife in the societies and damaged the cause, which suffered in public estimation from the intemperance of some of its advocates. The early promise of the movement was not fulfilled; it ceased to grow after a few years and then declined, both in the United Kingdom and in the United States. The most remarkable episode in the temperance campaign at this period was the mission of the Rev. Theobald Mathew of Cork, commonly known as Father Mathew, the greatest of all temperance missionaries. He travelled through Ireland in the years 1838–42 and everywhere excited intense enthusiasm. People flocked to hear him and took the pledge in crowds. In 1841 the number of abstainers in Ireland was estimated to be 4,647,000, which is more than the entire population to-day. In three years the consumption of spirits fell from 10,815,000 to 5,290,000 gallons. This was not all due to Father Mathew, because great depression and distress prevailed at the same time, but he unquestionably exercised an extraordinary influence. In 1843 he went to England, where he had less, though still great, success, and in 1850 to America. He died in 1856, by which time the cause had fallen into a depressed state in both countries. In the United States a flash of enthusiasm of a similar character, but on a smaller scale, known as the Washingtonian movement, had appeared about the same time. It was started in Baltimore by a knot of reformed drunkards in 1840 and was carried on by means of public meetings; many societies were formed and some half-million persons took the pledge, including many reformed drunkards. But the public grew weary of the agitation and enthusiasm died down. The decline of moral suasion and of the societies was followed by a tendency to have recourse to compulsion and to secure by legislation that abstinence from alcoholic drinks which the public would not voluntarily adopt or would not maintain when adopted. In 1845 a law prohibiting the public sale of liquor was passed in New York State but repealed in 1847; in 1851 state prohibition was adopted in Maine (see LIQUOR LAWS). The same tendency was manifested in England by the formation in 1853 of the United Kingdom Alliance "to procure the total and immediate legislative suppression of the traffic in intoxicating liquors as beverages."

Since that time the organized movement has embraced both elements, the voluntary and the compulsory, and has combined the inculcation of individual abstinence with the promotion of legislation for the reduction or suppression of the traffic. On the whole the latter has predominated, particularly in the United States, where organized agitation has for more than half a century made temperance a political question and has produced the various experiments in legislation of which an account is given in the article on LIQUOR LAWS. In 1869 a National Prohibition Party was formed. In Great Britain the political element has been less predominant but sufficiently pronounced to form a distinguishing feature between the early and more enthusiastic stage of temperance agitation, which after lasting some twenty years suffered a reaction, and the later one, which began between 1860 and 1870 and made way more gradually. In addition to combining the moral and the political elements the modern movement is characterized by the following features: (1) international organization, (2) organized co-operation of women, (3) juvenile temperance, (4) teaching of temperance in schools and elsewhere, (5) scientific study of alcohol and inebriety.

(1) International organization appears to have been started by the Order of Good Templars, a society of abstainers formed in 1851 at Utica in New York State. It spread over the United States and Canada, and in 1868 was introduced into Great Britain. Some years later it was extended to Scandinavia, where it is very strong. Temperance societies had previously existed in Norway from 1836 and in Sweden from 1837; these seem to be the earliest examples on the continent of Europe. The Good Templar organization has spread to several other European countries, to Australasia, India, South and West Africa and South America. There are several other international societies, and international congresses have been held, the first in 1885 at Antwerp. A World's Prohibition Conference was held in London in 1909. It was attended by about 300 delegates from temperance societies in nearly all parts of the world, and resulted in the foundation of an International Prohibition Federation, which embraces every country in Europe with three or four minor exceptions, the United States, Mexico, Argentina, the British self-governing Dominions, India, China, Japan, Palestine, Tunisia and Hawaii. The formation of this body indicates the growth of the most uncompromising form of antagonism to the liquor traffic. Its object is the total abolition of the legalized traffic throughout the world.

(2) The organization of women, which has also become international, dates from 1874, when the National Women's Christian Temperance Union was founded at Cleveland in the United States. In 1907 it had branches in every state in the Union and in about 10,000 towns and villages with an aggregate membership of 350,000. It employs all means, educational and social as well as political, but it has exercised great influence in promoting that drastic legislation which characterizes the United States. It has also taken up many other questions relating to women, in addition to temperance, and has adopted the badge of a white ribbon. About the year 1883 Miss Frances Willard, who had been the moving spirit of the Union, carried the organization of women into other lands and formed the World's Woman's Christian Temperance Union, which now possesses branches in some fifty countries with a total membership of half a million. It has held several conventions in America and Europe and circulated a polyglot petition, said to be the largest on record, which has been presented to a large number of sovereigns and other heads of states. There are several other female organizations in the United Kingdom.

(3) The inclusion of children in temperance organization goes back to 1847, when a society was formed at Leeds, in Yorkshire, of juvenile abstainers who had taken the pledge; it took the name of Band of Hope. The practice spread, and in 1851 a Band of Hope Union was formed. There are now a number of such unions, for the United Kingdom, Scotland, Ireland and separate counties in England; the Bands of Hope are said to number 15,000 in all. There are also several other juvenile organizations, some of which are branches of the adult societies. By far the largest is the juvenile section of the Church of England Temperance Society, which has 485,888 members (1910). Children's societies in the United States are usually called the Loyal Temperance Legion, but there are some Bands of Hope also. On the continent of Europe juvenile organizations exist in several countries and notably in Sweden and Belgium (*sociétés scolaires*).

(4) The teaching of temperance in schools, which has become a great feature of the moral propaganda, was begun by private effort in 1852, when the late Mr John Hope inaugurated a regular weekly visitation of day-schools in Edinburgh. In 1875 at the invitation of the National Temperance League, the late Sir Benjamin Richardson wrote his *Temperance Lesson Book*, which was adopted by many schools as a primer. In 1889 school-teaching by travelling lecturers was taken up by the United Kingdom Band of Hope Union, and the example was followed by many other societies. The Band of Hope Unions in England alone have spent over £3000 a year for the last twenty years in itinerant lectures; object-lessons on the nature and effects of alcoholic drinks are given to children in the higher standards. The Church of England Temperance Society carries on similar work in diocesan schools, and examines the children in the subject of temperance; in 1909 it had in use 6000 lantern slides for lectures, and set 7598 examination papers. The voluntary temperance teaching having grown continuously and become very extensive, has led to action by central education authorities. In 1906 the Board of Education in Ireland made "Hygiene and Temperance" a compulsory subject in the public schools. In 1909 the Board of Education for England issued a syllabus of temperance teaching, the adoption of which in elementary schools is optional. In Scotland also courses of teaching in hygiene and temperance are permissive and have been adopted by many local educational authorities. In the United States compulsory teaching is of much longer standing and more advanced. The question was first taken up by the Women's Christian Temperance Union (see above) in 1879; it was believed that by teaching the physiological effects of alcohol to all children the problem of intemperance would be effectually "solved," and a systematic political campaign was planned and carried out for the purpose of obtaining compulsory legislation to give effect to this idea. The campaign was successful in New York in 1884, in Pennsylvania in 1885 and subsequently in other states. Laws have now been passed in every state and territory, making anti-alcohol teaching part of the curriculum in the public schools, and tobacco is usually included. The manner of teaching has given rise to much controversy and opposition. Temperance is taught in connexion with physiology and hygiene, but the promoters of the movement insisted that prominence should be given to it and that the text-books should be adapted accordingly. Consequently a class of text-books came into use which were offensive to men of science and well-educated teachers because they contained false statements and absolute nonsense. The effect of forcing teachers to teach what they knew to be untrue was very unfortunate, and in some states the laws have undergone revision. With regard to other countries the practice varies greatly. School-teaching is compulsory in Canada, except in Quebec and Prince Edward Island, where it is permissive; in France since 1902; in Sweden since 1892, and in Iceland. It is recognized by authority but optional in Australia, South Africa, some provinces of India, Belgium, Finland, Denmark, Norway, Germany, Austria-Hungary and Switzerland. The movement in favour of school-teaching is continuously and generally advancing.

(5) The scientific study of the physiology and pathology of alcohol is a very large subject in itself. As has been shown above, the pioneers of the temperance movement were medical men; and though the Churches soon became the chief moving force, doctors have always exercised an influence, and in more recent times since people learnt to bow down to the name of Science there has been a marked tendency to have recourse to scientific authority for arguments and support, of which the teaching of temperance as a branch of physiology or hygiene is an illustration. At the same time the increasing interest taken in all questions relating to health has directed the attention of scientific investigators to this subject, while advancing knowledge of physiology, pathology and chemistry in general and improved means of investigation have enabled them to pursue it in various directions. Consequently a large amount of research has been devoted to alcohol and its effects both by experimentation on animals and plants and by observation of the morbid conditions set up in human beings by excessive and long-continued indulgence in alcoholic drinks. Another field of inquiry which has been actively worked is the statistical study of drink in relation to nationality, occupation, disease, insanity, mortality, longevity, crime, pauperism and other aspects of social life. In London there is a society, consisting chiefly of medical men, for the scientific study of inebriety; it holds periodical meetings at which papers are read and discussed. But the subject is being worked at in every country, and a vast mass of information has been accumulated. An attempt will be made later on to summarize the more important results of this activity. There is no doubt that it has exercised a strong influence on public opinion and on the whole in the direction of temperance. A great change of attitude has taken place and is still going on. The ill-effects of excessive drinking, especially of distilled spirits, have long been recognized, but the tendency now is to question whether any alcohol-containing drinks are of any value at all and to deny any valid distinction between distilled and fermented liquors. Medical abstinence societies have been formed in England, Germany, Belgium, Holland, Norway, Sweden and Denmark.

Present State of the Movement.—No comprehensive data are available for estimating the numerical strength of the temperance organizations or the number of abstainers at the present time; but the *Alliance Year Book* contains a directory of societies, which at least give some idea of the wide distribution of the movement. The following summary figures are extracted from the list; they relate to distinct organizations, exclusive of branches and sub-sections, having for their object the promotion of individual abstinence or of legislation: The United Kingdom, 62; Australasia, 11; Canada, 2; South Africa, 3; India, 2; United States, 10; Austria-Hungary, 8; Belgium, 2; Denmark, 5; France, 4; Germany, 12; Holland, 6; Sweden, 6; Switzerland, 11. The figures are no doubt very imperfect and must not be taken in any way to represent the relative strength of temperance organizations in the several countries. The list for the United Kingdom is much more complete than for the other countries. The *Alliance Year Book* indeed gives the names of 130 organizations in the United Kingdom connected in some way with temperance work; but these include local branches, juvenile sections, insurance companies, orphanages and so on. An attempt has been made to pick out the temperance societies as ordinarily understood; but some of those included are merely committees for promoting particular pieces of legislation, and on the other hand bodies like the Salvation Army and the Church Army, which do a great deal of temperance work but are not primarily and principally engaged in it, have been omitted. Altogether the subject is full of confusion and not susceptible of exact statement. The number of societies is no guide to the number of individuals, for many persons belong to several organizations. There can be little doubt that the organized movement is numerically strongest in the United States and next strongest in the United Kingdom, but no reliable estimates can be made.

Some of the British societies call for particular notice. The two principal ones are the Church of England Temperance Society and the United Kingdom Alliance. The latter, founded in 1853, is the chief fighting political organization, having total prohibition of the liquor traffic for its object; its income is about £12,000 a year. The Church of England Temperance Society is much the largest of the British societies. It was founded in 1862 and reconstituted in 1873 on a dual basis of total abstinence and general

anti-intemperance. Its objects are (1) the promotion of habits of temperance, (2) the reformation of the intemperate; (3) the removal of the causes which lead to intemperance. Thus it embraces both the moral and the legislative spheres, but the former takes first place; and this was emphasized in 1909 by the inauguration of a "forward movement" in spiritual activity. On the legislative side the society supports measures of reform rather than prohibition, and particularly reduction of licences and popular control of the traffic. Its activity is many-sided; it carries on an extensive publication department and educational courses, police court and prison gate missions, missions to seamen, travelling vans, and inebriate homes, of which there are 4 for women and 1 for men. It works locally through 36 diocesan branches, of which the aggregate expenditure in 1909 was £41,353, exclusive of the central office. It has Church temperance societies in Scotland and Ireland affiliated to it, as are the missions to seamen, and it has given birth to a temperance mission for railway workers and a Church benefit society. Its comparative moderation contrasts strongly with the extreme views of many temperance bodies. One of its departments is a semi-teetotal association, which was founded separately in 1903, but came under the society in 1904; the members pledge themselves to abstain from alcoholic liquor between meals. This department, which revives an old form of pledge, has been very successful; it is found that members frequently go on to take the full pledge. The total membership of the Church of England Temperance Society in 1909 was 636,233, thus distributed:—General section, 35,901; total abstainers, 114,444; juvenile members, 485,888. The enormous number of juvenile members is significant. The numerical strength of the temperance societies in general, which is often greatly exaggerated, seems to be largely made up by the juvenile contingents, so far as information is available. Other noteworthy British societies are the Royal Army Temperance Association and the Royal Naval Temperance Society. The special liability of soldiers and sailors to intemperance makes the work of these bodies particularly valuable, and it is strongly supported by the king and many officers of the greatest distinction. Very striking results have been obtained in the army. Twenty-five per cent of the Home Forces and 42 per cent. of the Indian army belong to the association; and the movement is growing. In the navy 25,000 men have joined the Temperance Society.

Like other propagandist causes of the day the temperance movement is supported by an enormous output of literature, including books, pamphlets, leaflets and periodicals. The *Alliance Year Book* gives a list of the latter. It names over 40 in the United Kingdom; the great majority are penny monthly magazines, but three societies conduct weekly journals—namely, the Church of England Temperance Society (*Temperance Chronicle*), United Kingdom Alliance (*Alliance News*) and the International Order of Good Templars (*Good Templars' Watchword*). Several Nonconformist churches have weekly papers in which temperance work is specially noted, as in the *War Cry*, the journal of the Salvation Army. For other countries the number of journals is given as follows:—Australasia, 10 (one weekly); Canada, 7 (3 weekly); India, 5; South Africa, 2; U.S.A. 15 (2 weekly); Austria, 2; Belgium, 2; Denmark, 1; France, 2; Germany, 8; Holland, 2; Italy, 1; Norway, 2; Russia, 1; Sweden, 7; Switzerland, 3. The list is no doubt imperfect. In the United States newspapers of all kinds are many times more numerous than in the United Kingdom, and the American *Prohibition Year Book* names 21 "leading" prohibition papers, of which 16 are weekly and 1 daily. There are probably hundreds of temperance journals in the United States.

Effect of the Temperance Movement.—The organized agitation against the abuse and even the use of alcoholic liquors thus briefly described is a very interesting feature of social life in the present state of civilization; but when a serious attempt is made to ascertain its results the inquiry is found to be beset with difficulty. It has no doubt been largely instrumental in procuring the varied mass of legislation described in the article on LIQUOR LAWS, particularly in the United States, the United Kingdom and Scandinavia; and these laws are in a sense results. Ardent advocates of legislation, who are always apt to substitute the means for the end, point to them with satisfaction. Those who demand prohibition regard its adoption by this or that community as an end in itself and a proof of "progress"; more moderate reformers view the reduction of public-houses in the same light. Facts of this kind can be stated with precision, but they go a very little way. The real point is not the law or the number of houses, but the habits of the people, and what we want to know is the effect on them of legislation, of organization, moral persuasion and the other influences that go to make up the Temperance Movement. To this question no clear or general answer can be given. There is a good deal of information about the United Kingdom, where the subject has been much more fully studied than anywhere else, and about Norway and Sweden, but for other countries valid data are lacking to show whether intemperance has increased or diminished. The fullest statistical evidence available relates to the consumption of drink.

Consumption of Drink.

International Statistics.—In 1906 a return was published by the British Board of Trade giving the production and consumption of alcoholic beverages in different countries for the years 1891–1905. The table on p. 581 is compiled from it. Information is also given in the returns for Spain, Portugal, the Balkan States and South Africa, but it is very imperfect and has therefore been omitted.

The only considerable movement during the 15 years covered by the table is a marked increase in the consumption of beer. It has occurred in some measure in the following countries:—Russia, Sweden, Denmark, France, Belgium, Switzerland, Italy, Austria, United States, Canada, Australia, New Zealand. The rise is notably large in Sweden, France, Switzerland, United States and Canada; and the upward movement has been particularly steady since 1898 in the United States, Canada and New Zealand. Exceptions are the United Kingdom and Norway, in both of which the consumption has fallen largely and steadily since 1899. In Germany it has also fallen somewhat since 1900, but not so steadily, and over the whole period it has risen in that country. It is impossible to connect these various movements either with legislation or with temperance organization. If the fall in Norway is ascribed to them, it must be pointed out that they are much more directed against spirits than against beer in that country, and the consumption of spirits shows no such movement, having risen since 1897. No one who has studied the subject in the different countries affected can doubt that the general rise is due to the introduction and growing popularity of the light beers originally brewed in Germany and Austria, and commonly called "lager." This is notably the case in France, Belgium, Sweden and North America. It is an instance of the force of popular taste. The increase in beer has not been accompanied by a corresponding reduction of other alcoholic liquor. Wine might be left out of account in this connexion. It is largely consumed only in countries where it is extensively grown, namely, in France, Italy and Switzerland, out of the countries enumerated. The consumption is very irregular and dependent mainly on the abundance of the crop. But the tendency of wine has also been to rise; it has risen in France, Belgium, Italy, Austria, the United States and Australia. With regard to spirits, the only general movement is that consumption has fallen in most European countries since 1900. But this does not appear to be compensatory to the rise of beer, which extends over the whole period and went on when spirits were rising too. Exceptions to the downward movement of spirits since 1900 are offered by the United States and Canada, and to a less extent by Russia, Italy and Norway. The only country in which all classes of drink have steadily fallen is the United Kingdom; this singular fact will be discussed presently, but its peculiarity should be noted here in connexion with other countries.

Attempts have been made to express the total consumption of each country in terms of alcohol by allowing a certain percentage of spirit for wine and beer and reducing all three to a common denominator. The calculation yields a simple and uniform measure of comparison and permits the classification of the countries in the order of their alcoholic consumption; but it must be regarded as a somewhat arbitrary estimate, because the strength of both wine and beer varies considerably. The *Brewers' Almanack* gives the following table based on the returns quoted above:—

Consumption of Alcohol at Proof Strength in Gallons. Annual Average per Head, 1901–5.

	Wine.	Beer.	Spirits.	Total.
France	7·70	0·63	1·36	9·69

Apart from the gaps in the information, which speak for themselves, allowance must be made for other defects. In no case is the nominal consumption per head a valid index to the relative temperateness of different peoples unless other conditions are fairly equal. The distribution of the drinking has to be taken into account, and this is conditioned by the age and sex constitution of the population and by the habits of the people. A country in which every person except infants takes a minute quantity of drink at every meal every day will have a far larger consumption per head and yet may be far more temperate than one in which a large proportion of the population takes none at all and the drinking is concentrated in regard to both time and person. The Portuguese and Spaniards, for instance, are more temperate than any of the nations below them on the list; drunkenness is never seen in Portugal and in the south of Spain (the bishop of Birmingham has publicly borne testimony to the sobriety even of such a large seaport as Barcelona). The aggregate consumption is brought up to a comparatively high level by the national practice of drinking a little wine freely diluted with water, a beverage which contains less alcohol than many "temperance" drinks. In like manner the French and Italians, whose high place is due to wine, are more sober than most of the nations ranged below them. The writer has made extensive inquiries on this head in France. There is drunkenness, to which Zola's *l'Assommoir* bears testimony, but outside Paris and the seaports it is rare. Employers of labour in all the principal industrial centres, including the mining districts of the north, agree on this point. The very high position of Belgium is mainly due to a prodigious consumption of beer, which is explained by the general practice of giving it to children. On the other hand, drunkenness is exceedingly prevalent in Russia, which is near the bottom of the list, and is due to the consumption of vodka. The comparatively small amount per head put down in the returns may, if it is correct, be explained by the very large proportion of children in the population. The opposite condition is illustrated by Western Australia, which has a consumption per head nearly thrice that of any other Australian province. These instances will show the conditions that must be taken into account in making international comparisons and the fallacy of measuring national sobriety by consumption per head.

Consumption in United Kingdom.—Statistics of consumption for a longer period of time than that covered by the table given above are available for the United Kingdom, the United States and Scandinavia, and they are of particular interest because these are the countries in which the Temperance Movement has been most active and productive of most legislation. The United Kingdom is distinguished by being the only country in the list which shows a distinct fall in the consumption of all three kinds of liquor since 1899. To estimate the significance of this interesting fact it must be placed in historical perspective. The following table, compiled from the official returns, gives the annual average consumption per head in decennial periods from 1831 to 1890, and subsequently for each year to 1909. No continuous record of beer was kept until after 1856.

United Kingdom:

Average Annual Consumption per head in Gallons.

Year.	Wine.	Beer.	Spirits.
1831–40	0·26	. .	1·11
1841–50	0·23	. .	0·94
1851–60	0·23	23·5	1·01
1861–70	0·42	27·5	0·94
1871–80	0·51	31·5	1·17
1881–90	0·38	27·7	0·99
1891	0·39	30·1	1·03
1892	0·38	29·7	1·03
1893	0·36	29·5	0·98
1894	0·35	29·4	0·96
1895	0·37	29·6	1·00
1896	0·40	30·8	1·02
1897	0·40	31·4	1·03
1898	0·41	31·9	1·04
1899	0·41	32·7	1·08
1900	0·42	32·2	1·18
1901	0·36	31·4	1·10
1902	0·35	30·6	1·01
1903	0·37	30·2	1·03
1904	0·31	29·5	0·99
1905	0·27	28·4	0·93
1906	0·27	27·9	0·91
1907	0·28	27·8	0·91
1908	0·27	27·6	0·90
1909	0·25	26·4	0·87

It will be observed that the consumption has oscillated up and down during the whole period of 79 years. More spirits were drunk in 1831–40 than in the three following decades, and more wine than in the two following decades. The decennial period of greatest consumption was 1871–80; and the highest points reached were: wine, 0·56 gal. in 1876; beer, 34·0 gals. in 1874; spirits, 1·29 gals. in 1875. Since then the consumption has always been lower, though with fluctuations. The up and down movement is always associated with the state of trade, and the connexion is well marked in the last ten years. The progressive fall is striking, particularly in regard to beer, which is the staple drink of the people; but the period is too short to warrant the inference that it represents a permanent movement which will continue. The fluctuations shown by the decennial table given above suggest the probability of a subsequent rise with a revival of trade. Chronic depression and unemployment have prevailed in many industries since 1900, and these conditions always cause a diminished consumption. Nevertheless they do not fully account for the movement here shown, because the fall in consumption has been progressive, whereas the state of trade has fluctuated considerably; the curves do not coincide. Some other factor has been at work, and there is reason to think that it is a gradual change in the habits of the people. The facts of consumption agree with much other evidence in pointing to this conclusion. The expenditure in drink is not so high as it used to be in the past, whether periods of prosperity or adversity are taken. The calculation of annual expenditure prepared for the United Kingdom Alliance, and commonly called the National Drink Bill, points to that conclusion. It is based on an arbitrary estimate of the cost of drink to the consumer and must not be taken to represent established facts; but it has some comparative value. The following table gives this calculation for the last 26 years:—

National Drink Bill, United Kingdom.

Year.	Total Expenditure.	Expenditure per head.	Year.	Total Expenditure	Expenditure per head.
	£	£ s. d.		£	£ s. d.
1884	144,734,214	4 1 0¼	1897	174,365,372	4 7 6¾
1885	141,039,141	3 18 3¾	1898	176,967,349	4 8 0¾
1886	140,550,126	3 17 4¾	1899	185,927,227	4 11 8
1887	142,784,438	3 18 0¼	1900	184 881,196	4 10 4¼
1888	142,426,153	3 17 2¾	1901	181,788,245	4 7 8¼
1899	151,064,035	4 1 3¼	1902	179,499,817	4 5 6¾
1890	159,542,700	4 5 1½	1903	174,445,271	4 2 4

1895	163,133,935	4 3 4½	1908	161,060,482	3 12 3¾
1896	170,426,467	4 6 4½	1909	155,162,485	3 8 11½

The table begins and ends in two periods of marked depression, with one of marked prosperity in between; but it is to be noted that in the earlier term of depression, although it was very acute, the expenditure never sank so low as in the later one. During the four lowest years (1885–88) the mean expenditure was nearly 4s. a head more than in the five lowest years (1905–9). At the other end of the scale the high-water mark in the table, which is the year 1899, shows an expenditure of £4, 11s. 8d.; but the previous high-water mark comparable with it, namely 1876, showed an expenditure of £5, 1s. 9d., when calculated on the same basis. The figures, therefore, rather confirm than contradict the general belief that the people have grown more temperate during the last 30 or 40 years. With regard to the expression "national drink bill," which tacitly suggests so much money thrown away on drink, it must be remembered that a large proportion is devoted to public purposes and would have to be found in some other way. In the year ending March 1909 the trade paid a direct contribution of £37,404,575 to the national exchequer in excise and customs duties, in addition to income-tax and local taxation; all this comes back to the public pocket. Then it also maintains directly and indirectly a population reckoned at 2,000,000. The net amount spent on drink which might have been saved and spent on other things is not more than a third of the total sum.

The United States.—The movement in the United States has been totally different. The figures below are taken from the statistical abstract of the U.S. government as quoted in the *American Prohibition Year Book.* The figures, it may be noticed, differ widely throughout from those given for the same years in the Board of Trade returns of international consumption quoted on p. 581. The discrepancy is too great and too constant to admit of any explanation, but that the two sets of returns are calculated from different bases. It illustrates the defects of these statistics and the need of caution in using them. The American figures show a far larger consumption in the United States than the English.

The most noticeable fact here shown is the continuous and large increase in the consumption of beer. Every year shows a rise down to 1908, when for the first time in 70 years a fall was recorded. It was continued in 1909, and being accompanied by a fall in spirits and wine also is no doubt mainly attributable to the financial state of the country. Down to 1880 beer was to a considerable extent taking the place of spirits, the consumption of which had previously been very high; but after that the steady increase in beer was not accompanied by a reverse movement in spirits; and from 1896 to 1907 all three kinds of liquor rose together, though not with equal steadiness. The rising consumption of beer has been accompanied by an enormous increase in home production, the capital invested in breweries having risen from 4 million dollars in 1850 to 515 million dollars in 1905. The consumption of spirits is at a much higher level than in the United Kingdom, and two considerations add greatly to the significance of the fact—one is that drinking takes place more between meals and less at them, and the other that it is more confined to men. Women, other than prostitutes,

do not frequent the bar as they do in the United Kingdom, and children not at all. The expenditure in drink, so far as it can be calculated, has fluctuated somewhat, but shows a general tendency to rise. The following table has been prepared by Mr G. B. Waldron, an American statistician. It is taken from the *Prohibition Year Book*, with the American currency converted into English on the basis of 4s. to the dollar, omitting fractions of a penny, for purposes of comparison with the British statistics given above.

1897	198,640,711	2	15	6	1908	335,167,639	3	16	11

Comparison with the British table shows at a glance an opposite movement in the two countries. While expenditure has steadily fallen in the United Kingdom since 1899, it has as steadily risen in the United States; and whereas in 1888 the expenditure in the former was 41 per cent. higher than in the latter, the two had drawn equal in 1906 and since then have changed places. Moreover the different system of taxation brings back a much larger proportion of the whole expenditure into the exchequer in the United Kingdom (see LIQUOR LAWS). The comparison is of much interest in view of the very different laws and regulations under which the trade is conducted in the two countries. It may be objected that the statistics are merely estimates, but both sets are put forward by the advocates of prohibition and are of equal authority, so that they hold good for comparison.

Norway and Sweden.—The statistics for these countries are imperfect, because there is no record of wine, and in recent years the use of spirits has been supplemented or replaced to a considerable extent by artificial wines heavily loaded with spirits. But, as they stand, the statistics derive special interest from the peculiar conditions under which the traffic is conducted. The Scandinavian company system was started in Sweden in 1865 and in Norway in 1871 (see LIQUOR LAWS).

The difference between these contiguous countries is remarkable. The consumption of spirits has always been much higher in Sweden than in Norway. In the old days before any legislation the estimated consumption was in Sweden 46 litres (1829) and in Norway 16 litres (1833) a head. In recent years, under the company system, the figures for both countries are vastly less, but the Swedish consumption has hardly ever been less than double the Norwegian and sometimes three times as great. This difference, observed over a long period before regulation and after, points to different conditions and national habits; but such constant differentiating factors hardly explain the strikingly dissimilar movements shown by the tables. Both countries are obviously affected by the state of trade. The high-water mark of spirit-drinking in modern times for both was the same period, 1874–76, as noted above for the United Kingdom; Sweden then averaged 12·4 litres a head and Norway 6·6. Both show also the influence of the 1900 boom in trade and the subsequent decline. But in Sweden the increase of beer-drinking, which in 1871–80 was less than in Norway, has been enormous. If the two drinks are put together it cannot be said that the consumption in Sweden was appreciably less in 1896–1905 than in 1871–80, whereas in Norway it was distinctly less. This may in part be explained by the substitution of the made wine, called laddevin, to which reference has already been made. The marked fall in the consumption of spirits which occurred in 1896–98 is attributed to this cause (Rowntree and Sherwell); the importation of wine rose from 2,320,300 litres in 1891–94 to 5,876,750 litres in 1898. Subsequently importation was checked by heavier duties and reduced consumption followed. In 1886–90 the quantity consumed per head in litres averaged 0·88; in 1896–1900 it was 2·49, with a maximum of 2·75 in 1898; in 1905 it had fallen again to 0·88 (Pratt).

A careful study of the foregoing statistics of consumption in the three countries—United Kingdom, United States and the Scandinavian peninsula—which have paid most attention to the problem and have for a long period applied forcible but widely different methods of control, does not permit any confident conclusion upon the comparative merits of any particular system. The United States, in whose multitudinous liquor laws prohibition plays the most prominent part, has most conspicuously failed to check consumption. Norway and Sweden, both of which combine the principle of disinterested management, though not in the same form, with a certain amount of prohibition, show markedly different results. The British licensing system has been at least as successful as any of the others. The most probable conclusion to be drawn from the facts is that the movement in each country has been mainly determined by other forces; the rise of consumption in the United States by the rapid and progressive urbanization of the people and the great increase of wealth; the diminution of consumption in the United Kingdom by a change in the habits of the people due to many causes, to which further reference is made below; while the difference between Norway and Sweden is largely due to differences of national character and habits already noted, though some influence must be attributed to the superior system and greater stringency of control in Norway. But if we go back to earlier periods there is no doubt at all that an incomparably worse state of things existed in the United Kingdom and in Scandinavia when the spirit traffic was under little control or none at all.

Intemperance.—Police statistics are the best evidence we have of the prevalence of drunkenness, which is the most visible and direct result of intemperance. Like other statistics, they must be used with due regard to the circumstances of origin and compilation. They vary according to (1) the laws relating to drunkenness; (2) the administration by police and justices; (3) the method of compiling returns. All these vary in different countries and towns and at different times, so that the statistics must not be used for minute comparisons. But properly handled they are of great value, and the discrepancies are less than might be supposed, because it is found on inquiry that the actual behaviour of the police towards drunken persons does not greatly differ. Neither exceptional zeal nor exceptional laxity lasts very long. The general practice is only to interfere with those persons whose violence causes disturbance or whose helplessness creates obstruction or annoyance. The mode of compiling returns is the most serious cause of error. Many countries have no returns, and in others they are incomplete. Those available, however, throw considerable light on the subject. The following quinquennial table shows the movement in England and Wales since the drunken period 1874–78. The important act of 1872, which increased the number of offences, vitiates comparison with the earliest returns, which are, however, given in the article on DRUNKENNESS.

Drunkenness, England and Wales.

Number of Persons proceeded against per 10,000.

1874–78	81·2	1894–98	60·4
1879–83	69·7	1899–1903	65·5
1884–88	63·6	1904–08	62·4
1889–93	61·4		

There has been a marked improvement since 1874–78, and on the whole a progressive one, though interrupted by a moderate rise in the period of prosperity about 1900. The figures for the most recent years would be considerably lower but for the Licensing Act of 1902, which altered the police procedure and caused a sudden rise, as shown by the following table, for the last 10 years:—

1900	63·4	1905	64·2
1901	64·5	1906	61·3
1902	63·6	1907	60·1
1903	69·0	1908	59·3
1904	67·4	1909	53·2

When allowance is made for the act of 1902 it is seen that the movement of drunkenness corresponds broadly with that of consumption, but the decline of drunkenness is more marked; the level is lower than it used to be whether good or bad times be taken. This plainly shows a large change in the habits of the people, which is further emphasized by the fact that police procedure has become more stringent and the returns more complete. The exceptional figure for 1909 (estimated) is ascribed to the heavy increase of spirit duties in that year. The change has been accompanied by a continuous fall in the number of public-houses in proportion to population. Between 1870 and 1909 the number of "on" licences was reduced from 53·3 to 26·3 per 10,000 of the population; but the correspondence between the two movements is not exact. The number of public-houses has fallen steadily from year to year, whereas drunkenness, like consumption, has fluctuated with the state of trade. The facts, therefore, demonstrate a connexion, but hardly establish one of cause and effect. The principal causes which have brought about the general decline of drunkenness are wider and deeper. The standard of behaviour has gradually changed with education and the provision of alternative recreations in many forms, among which the chief are games, theatres, locomotion, public libraries, institutes, tea shops and eating houses. At the same time great social changes have taken effect and have tended to remove class barriers and foster the aspirations of the working classes, who have more and more adopted the standard of conduct prevalent among the more highly educated sections of society. The old drinking habits of the latter, which were notorious at the end of the 18th century, began to give way to greater sobriety early in the 19th century; and the movement was greatly promoted, as a feature of social life, by the influence of Queen Victoria's reign. Drunkenness went "out of fashion," and the social standard has gradually permeated downwards. All this has no doubt been stimulated by temperance organization and teaching, which has constantly kept the question before the public and exercised an educational influence in spite of ridicule and abuse. The change has been very gradual, but far greater than can be shown in figures. It can be better realized by contrasting the present state of things with that described in the past, as in the evidence given before a select committee of the House of Commons in 1834, when witnesses described the scenes that regularly occurred on Sunday morning in London—the crowd round the public-houses, women with babies to which they gave gin, and people lying dead drunk in the streets. The evidence given at this inquiry and by contemporary writers reveals a condition of things to which modern times afford no parallel; and in particular it disposes of the current belief that female drunkenness is a comparatively new thing and increasing. The practice of frequenting public-houses and drinking to excess in England has been noted for centuries and repeatedly denounced. It was described at a meeting of the Middlesex magistrates in 1830, when the chairman said that of 72 cases of drunkenness brought up at Bow Street on the previous Monday the majority were women "who had been picked up in the streets where they had fallen dead drunk." At the inquiry of 1834 Mr Mark Moore gave the number of customers counted entering 14 public-houses in a week; out of a total of 269,437 there were 108,593 women and 18,391 children. Of late years the proportion of female drunkards to the whole has been perceptibly diminishing. In 1870 the proportion of females to the total number proceeded against for drunkenness was 25·9 per cent.; in 1890 it was 23·4 per cent. The percentage of convictions credited to women in the last few years is: 1905, 20·42; 1906, 20·60; 1907, 20·26; 1908, 20·13; 1909, 19·79.

The foregoing observations on drunkenness apply only to England and Wales. The returns for Scotland and Ireland are less complete, but they show the movement in those parts of the kingdom. In Ireland a diminution has taken place in recent years, but in Scotland an increase.

Number of Charges of Drunkenness.

Year.	Scotland.	Ireland.
1890	36,293	100,202
1900	43,943	97,457
1901	..	88,295
1902	..	91,276
1903	36,930	85,502
1904	41,852	81,775
1905	43,518	79,968
1906	55,408	77,262
1907	58,900	76,860
1908	55,104	..

It is worthy of note that police drunkenness is higher in Wales, Scotland and Ireland than in England. The respective number of proceedings per 10,000 in the year 1907 was: England, 59·8; Wales, 65·2; Scotland, 123·3; Ireland, 175·6. The figures for Wales are strictly comparable, those for Scotland and Ireland less so; but the coincidence is striking. The greater prevalence of spirit drinking as a national habit, particularly in Scotland and Ireland, may account in part for the discrepancy. Other points which distinguish the three countries from England are their Celtic blood and Sunday closing. No connexion can be shown between the number of licensed houses and the prevalence of drunkenness; they are fewer in Scotland than in England and Wales, but more numerous in Ireland, though there has been a diminution there since 1902, which may have something to do with the fall of drunkenness. The same lack of correspondence is shown more fully by the detailed figures for England and Wales published in the official volume of licensing statistics. Taking the county boroughs in groups according to the number of licences in proportion to the population we get the following:—

Licences and Drunkenness, County Boroughs, 1905.

Licences per 10,000	under 20	20 to 30	30 to 40	40 to 50	over 60
Convictions per 10,000	71·05	55·89	62·4	36·6	35·27

The corresponding figures for the counties are as follows:—

Licences and Drunkenness, Counties, 1905.

Licences per 10,000	under 30	30 to 40	40 to 50	over 50
Convictions per 10,000	57·39	36·74	40·0	33·2

If any other year be taken similar discrepancies are shown. In 1909 the six counties with the highest and the six with the lowest number of licences exclusive of county boroughs, gave the following results:—

County.	Licences per 10,000.	Convictions per 10,000.	County.	Licences per 10,000.	Convictions per 10,000.
Huntingdon	91·51	20·60	Middlesex	11·84	33·32
Cambridge	74·04	11·18	Northumberland	19·09	133·12
Oxford	63·68	9·56	Essex	19·13	16·95
Brecon	63·28	54·34	Glamorgan	20·56	75·34
Rutland	61·79	14·14	Lancaster	21·43	38·45
Buckingham	59·72	15·76	Durham	21·67	80·49
Mean	69·00	20·93	Mean	18·95	62·94

It is curious that the mean figures for these two groups at opposite ends of the scale almost exactly reverse the number of licences and convictions; but the individual discrepancies show that other factors really determine the results. The chief of these is unquestionably occupation. All the counties with the highest number of convictions are pre-eminently mining counties. Year after year Northumberland, Durham and Glamorgan occupy the same place at the head of the convictions, and other mining counties are always high up. These areas are not drunken because the public-houses are few, but vice versa; the licences are kept down because of the drunkenness. The influence of occupation and character is further revealed by a broader survey. The following table from the judicial statistics for 1894 brings out these elements very clearly:—

Persons Proceeded Against for Drunkenness per 10,000.

Seaports	126·07
Mining counties	113·67
Metropolis	63·74
Manufacturing towns	47·00
Pleasure towns	28·93
Agricultural counties—	
(1) Home counties	24·50
(2) South-Western	20·94
(3) Eastern	10·99

In other countries the same distribution is observed; drunkenness is most prevalent in seaports and mining districts. It is further fostered by a northerly situation, and these three factors go far to explain the condition of Scotland, as of Northumberland and Durham.

The United States.—The Census Bureau at Washington issues from time to time statistics of cities, which contain a good deal of information concerning drunkenness. The last return, published in 1910, contains details of 158 cities having a population of over 30,000 in the year 1907, to which the statistics relate. It appears from these returns that drunkenness is exceedingly prevalent in American towns. The figures are not comparable with the English ones, because they relate to arrests, which are more numerous than "proceedings" and still more than convictions. The number of women included is very considerable, but the data are too imperfect to permit the calculation of a general percentage. In New York the proportion of women arrested for drunkenness and disorder was 24·3 per cent. of the whole number. The cities are divided into four groups according to population:—(1) over 300,000, (2) 100,000 to 300,000, (3) 50,000 to 100,000, (4) 30,000 to 50,000. The average number of arrests per 10,000 inhabitants in each group and in all cities together is—(1) 191·0, (2) 193·6, (3) 245·8, (4) 244·8; mean of all cities, 205·1. The comparatively small range of difference between the groups is remarkable, and indicates a general prevalence of police drunkenness. The higher figures for groups (3) and (4) are explained by the excessive number of cases in certain manufacturing, mining and Southern coloured towns of small and medium size. These figures are for drunkenness alone, so that they cannot be confused with other offences; but on examining the details of individual cities it becomes clear that the practice varies considerably in making up the returns, and that in some places nearly all the arrests of drunken persons are charged to drunkenness whereas in others a large proportion are returned under the head of disorderly conduct. In considering the relation between drunkenness and the number of licensed houses, therefore, it seems desirable to put both sets of figures, as in the following table. It will be seen that there is no correspondence between the number of licensed houses and the amount of drunkenness alone or of drunkenness and disorderly conduct together, except that the fourth group has the largest number of licences and the most disorder.

Arrests and Licences per 10,000.

Cities.	Arrests, Drunkenness.	Arrests, Disorderly Conduct.	Retail Liquor Dealers.
Group 1 Over 300,000	191·0	108·8	30·3
Group 2 100,000 to 300,000	193·6	112·8	27·7
Group 3 50,000 to 100,000	245·8	78·7	28·4
Group 4 30,000 to 50,000	244·8	121·4	31·5
Mean	205·1	106·8	29·6

There are large discrepancies between different cities, but not greater than among British towns. The following table gives the figures corresponding to the above for each of the great cities included in group 1, with the exception of San Francisco, the population of which could not be estimated:—

Arrests and Licences per 10,000.

Cities.	Arrests, Drunkenness.	Arrests, Disorderly Conduct.	Retail Liquor Dealers.
New York	105·9	120·2	25·5
Chicago	169·1	5·3	34·2
Philadelphia	287·5	81·0	13·1
St Louis	106·3	173·7	33·5
Boston	614·9	16·9	13·5
Baltimore	75·1	302·5	41·3
Pittsburg	331·4	236·9	15·3
Cleveland	355·2	34·9	40·4
Buffalo	318·9	153·3	38·4
Detroit	87·2	82·5	46·9
Cincinnati	82·4	66·4	44·8
Milwaukee	100·5	53·1	70·4
New Orleans	239·5	220·7	50·0
Washington	130·6	338·4	16·6

To a certain extent the same inverse relation appears here as in England; the places with the smallest proportion of licences—namely, Philadelphia, Boston, Pittsburg and Washington—are conspicuous for drunkenness and disorder, while those with the largest proportion of licences—namely, Detroit, Cincinnati, Milwaukee and New Orleans—are distinguished by the lowest amount, with the exception of New Orleans, which is a special case by reason of the large coloured and Creole population. The exceptional position of Boston is obviously due to exceptional police activity and that of Chicago to the opposite. At Boston and Cleveland, it will be noticed, the police prefer the charge of drunkenness; at Baltimore the opposite. The position of Washington is explained by the very large coloured population and the strength of the police force, which is greater in the capital than elsewhere and very strict in regard to order in the streets. Philadelphia, Pittsburg and Cleveland are great manufacturing centres with a large population of foreign workmen; the vast influx of European immigrants, consisting of men disposed to drink by age, occupation, race and habits, and receiving higher wages than they have been used to, must always be borne in mind with regard to drunkenness in the United States. It is interesting to note the condition of those cities in which there is no licensed trade. There are none such in the first two groups, but 14 in the third and fourth groups. The following are the figures:—

Arrests for Drunkenness and Disorder per 10,000.

Group 3		Group 4	
Cambridge (Mass.)	218·5	Topeka (Kansas)	227·1
Kansas City (Kansas)	178·0	Malden (Mass.)	100·8
Somerville (Mass.)	130·5	Chelsea (Mass.)	336·0
Charleston (S. Carolina)	342·7	Salem (Mass.)	329·0
Portland (Maine)	605	Newton (Mass.)	168·1
Brockton (Mass.)	240·9	Wichita (Kansas)	392·7
		Fitchburg (Mass.)	161·5
		Everett (Mass.)	99·6

The majority are prohibition cities in Massachusetts, the only state in which this measure was applied to any place of considerable size in 1907. In all of them the drunkenness is below the mean for the group and considerably below that of similar and neighbouring towns. For instance, Brockton is a boot-manufacturing town, comparable with Lynn in the same state; the respective figures are 240·9 and 561·1. The evidence here, so far as it goes, is in favour of local prohibition. On the other hand there are a number of licensed cities with lower figures, and two of those on the list—Chelsea and Salem—are very high up. State prohibition does not make such a good showing. Portland is one of the most drunken places in America—a fact confirmed by many observers—and Wichita in Kansas is above the mean. Kansas City is better. This place is peculiarly situated, being continuous with Kansas City in Missouri; the boundary between the two states passes through the town. Consequently the inhabitants have only to go into the Missouri half to obtain drink. Cambridge is very similarly situated in relation to Boston. Charleston, which is above the mean for the group, was under the state dispensary system. In sum, these police figures furnish some argument for prohibition and some against; but they clearly demonstrate the limits of compulsion. Altogether the statistical evidence from the United States, whether of consumption, expenditure or drunkenness, offers no inducement to the United Kingdom to adopt any of the American methods of control in place of its own system.

Norway and Sweden.—Police statistics for some of the principal towns in Norway and Sweden, which are the seats of the company system or disinterested management applied to spirit bars, are frequently quoted and we will therefore give them here. When all allowances have been made they show that drunkenness is very prevalent in these seaport towns, and that it fluctuates as in England but exhibits no general tendency to improvement.

Convictions per 1000 *in Gothenburg.*

1865	46	1886	31
1866	30	1887	32
1867	29	1888	31
1868	26	1889	34
1869	28	1890	40
1870	26	1891	44
1871	28	1892	42
1872	28	1893	38
1873	32	1894	34
1874	38	1895	31
1875	42	1896	35
1876	39	1897	44
1877	40	1898	54
1878	32	1899	54
1879	31	1900	51
1880	31	1901	42
1881	32	1902	45
1882	29	1903	47
1883	30	1904	45
1884	29	1905	52
1885	29		

The principal feature of this table is the much higher level in the second 20 years than in the first, though the police procedure has been the same. Several times in recent years the figure has exceeded that of 1865, which was practically the year before the company system was introduced, as it did not begin operations until October. Once more the influence of trade oscillations is well marked, particularly in the prosperous period of 1897–1900. To convert convictions into arrests for comparison with the following tables about 3 per 1000 should be added; this difference is very evenly maintained in Gothenburg.

Arrests per 1000 *in Bergen.*

Use and Abuse of Alcohol.

The evils caused by the abuse of alcoholic liquors have always been recognized by mankind; they are too obvious to be ignored. Intoxication produces imbecility, bestiality, violence and crime; continued excess produces incapacity, poverty, misery, disease, delirium, insanity and death. But all these effects are produced by other causes and it is very difficult to estimate the precise share of this particular agent. In modern times scientific investigation has attempted to do this and to give precision to the conclusions drawn from ordinary observation. We will briefly summarize some of the results.

Crime.—Drink is associated with crimes against the person, but not with crimes against property, which form in England nine-tenths of the whole (Judicial Statistics, 1901). Dr W. C. Sullivan, medical officer in the prison service, calculates that "alcoholic intoxication is answerable for about 60 per cent. of indictable crimes of violence and for a rather higher proportion of minor offences of the same class"; and further that "it is probably the cause of nearly half the crimes of lust," but it "makes no appreciable contribution to crimes of acquisitiveness." He gives the following table:—

Annual Average per 100,000—1891–1900.

Areas.	Drunkenness.	Homicides and Assaults.	Attempted Suicide.
Agricultural	226·3	116·33	3·46
Mining	1091·2	237·34	2·43
Manufacturing	479·8	265·73	6·42
Seaports	990·6	409·73	10·56

This does not show a regular connexion. The mining areas, which have the most drunkenness, are only second in violence and lowest of all in suicide. Dr Sullivan explains this discrepancy by the theory that chronic alcoholism is less prevalent among miners, and that this form is chiefly responsible for the crimes in question. It is impossible, however, to establish any constant relation between drink and violent crime; the two do not vary together. It was pointed out in the Judicial Statistics for 1901 that whereas in the drunken year 1899 consumption of drink was 8 per cent. higher and the police records of prosecutions for drunkenness 15 per cent. higher than in the previous quinquennial period, crimes of violence were 1·62 per cent. lower. These statistics apply only to England. When other countries are taken it becomes still clearer that other factors are more important. Mr W. D. Morrison gives the following table of homicides in proportion to population in different countries (*Crime and its Causes*):—

Persons Tried for Homicide per 100,000.

Italy	15·40	France	2·73
Spain	11·91	Scotland	2·11
Austria	4·01	Germany	1·61
Ireland	3·35	England	1·60
Belgium	3·02	Holland	1·10

Except that England, Scotland and Ireland are in the order of relative drunkenness, the table shows no correspondence between drink and homicide. National character and climate are evidently more important determining factors. Some calculations of the proportion of crime associated with drink have been made in different countries. In Germany 36·5 per cent. of the prisoners in one gaol were found to be drunkards (Baer); assaults, 51·3 per cent.; resistance to the police, 70·1 per cent.; offences against morality, 66 per cent. (Aschaffenburg). In Italy 50, 60, and 75 per cent. of crimes against the person have been attributed to drink. In Switzerland 40 per cent. of male criminals in 1892 were found to have been under the influence of drink when their offences were committed. In Denmark 43 per cent. of the men convicted in 1903 were drunkards. These estimates, some of which are official, suffice to confirm the connexion between drink and a great deal of crime, but the basis of investigation is too narrow to permit more than a general conclusion. There is, however, one form of crime for which drink is almost wholly responsible, and this furnishes the blackest of all indictments against it. The intensity of suffering and injury inflicted on children by the atrocious cruelty and neglect of drunken parents cannot be overstated. The Society for the Prevention of Cruelty to Children finds that 90 per cent. of the cases which come under its notice are due to drink.

Poverty.—Much poverty is undoubtedly caused by drink, but it is even less possible to establish any constant connexion between the two than in the case of crime. Pauperism and drink stand to a great extent in inverse relation; in good times the first diminishes and the second increases, in bad times the reverse takes place. For instance, pauperism in England, which has had a general tendency to fall for many years, rose rapidly in the period of low consumption after 1860, fell still more rapidly in the great drinking years 1870–77, and rose again when they gave place to depression. With falling consumption after 1891 (see the table above) it rose till 1894, when the opposite movement began; and during the steady fall of drink since 1900 pauperism has been rising again. The only exception to this regular inverse movement is the very depressed period 1884–1888, when pauperism was stationary. The conclusion to be drawn is that while drink is a chief cause of poverty in many cases and the sole cause in some, it is swamped in the aggregate by the larger influence of work and wages. Mr Charles Booth's statistical investigation in East London resulted in the following estimates of the percentage of poverty caused by drink: "great poverty" (the two lowest classes)—drink, 9 per cent., drunken or thriftless wife, 5 per cent.; "poverty" (the two next classes) the figures were—drink, 7 per cent., drunken or thriftless wife, 6 per cent. These results can hardly be said to confirm the opinion that drink is the chief cause of poverty; they rather agree with the conclusions drawn from the movement of pauperism. Mr Rowntree's investigation of poverty in York did not enable him to make any numerical estimate; drink was not among the chief causes of "primary" poverty (the lowest class), but he thought it the "predominant factor" in producing "secondary" poverty. Alderman McDougall's inquiry in Manchester (1883) resulted in the following proportions of drink-pauperism:—Male drunkenness, 24·32 per cent.; female, 4·40 per cent.; widows and children of drunkards, 21·84 per cent. An inquiry conducted in 1894–95 by the Massachusetts Bureau of Statistics of Labour found that 39·44 per cent. of paupers attributed their position to their own intemperance and about 5 per cent. to that of their parents. All these inquiries are on a very small basis, and the last is particularly deceptive. Drink is commonly confessed by criminals and paupers, as a venial offence to serve as a plausible excuse for a condition really due to dislike of work. When poverty is examined by local distribution it is found to have very little connexion with drink. In 1901 the average proportion of pauperism to population in England was 5·3 per cent. The exceptionally drunken districts of Northumberland and Durham were all below it, the sober eastern counties all above it (Blue-book on Public Health and Social Conditions, Col. 4671).

Insanity.—Dr Robert Jones finds that 16 per cent. of all the persons (7182 out of 43,694) admitted into the London asylums during the twelve years 1893–1905 "were definitely ascertained to owe their insanity to drink or intemperance." The proportion in Claybury Asylum during the same period was 17 per cent., being 22 per cent. of the men and 12 per cent. of the women. Dr R. H. Crowley says:—"One may safely assert that from 20 to 25 per cent. of all cases of insanity under the poor law are directly due to intemperance." Dr T. B. Hyslop says:—"With regard to insanity there is some difference in experience as to the relative frequency of alcohol in its causation. This difference ranges from between 10 and 30 per cent. . . . My own experience leads me to believe that alcohol is either a direct or an indirect factor in the causation of at least 50 per cent. of the cases of insanity." Dr T. S. Clouston estimates that alcoholic excess is the cause of about 20 per cent. of all the insanity in Great Britain and Ireland. These are the opinions of experienced medical men in charge of the insane. On the other hand, those in charge of inebriates are inclined to attribute inebriety to a great extent to mental deficiency of some kind. Dr Branthwaite, government inspector under the Inebriates Acts, observes in his Report for 1908, published in 1910, "There is no doubt whatever in detaining and treating persons sent to us under the Inebriates Acts that we are dealing to a large extent with a class known as 'feeble-minded.' . . . It would be difficult to find many more than about a third of all persons under detention capable of passing muster as of average mental capacity." In support of this statement he gives the following classification of 3032 cases:—

Classification.	Number.	Percentage.
(1) Insane; persons since admission certified and sent to asylums	63	14·51
(2) Very defective; persons more or less congenitally imbecile, degenerate, or epileptic	377	
(3) Defective; eccentric, silly, dull, senile, or subject to periodical paroxysms of ungovernable temper	1487	49·04
(4) Of average mental capacity, on admission or after six months' detention	1105	36·45

Insanity is therefore a cause as well as a consequence of excessive drinking, and the estimates given about it must be qualified accordingly. The following are given for foreign countries. In Italy a report from 26 asylums returned 18·6 per cent. as directly or indirectly (by heredity) due to alcoholism. Professor Seppili reports from the Brescia asylum the following: 1894–98, 15·7 per cent.; 1899–1903, 19·8 per cent.; 1904–08, 27·6 per cent. Experts in such statistics will recognize at once in this enormous rise a change in the method of classification. In Switzerland, of the admissions in 1900–04, 21·1 per cent. among males and 4·37 per cent. among females were alcoholics. In Denmark, of the admissions in 1899–1903, 21·37 per cent. were alcoholics. In Austria, of the admissions in 1903, 14·0 per cent. were alcoholics. In France the proportion of all persons in asylums in 1907 with an alcoholic history was 12·5 per cent.

Mortality.—The influence of drink on mortality is an unascertainable quantity, because it may be associated with other causes to an extent which varies in an infinite series of gradations. All attempts to estimate it are more or less plausible guesses. We have, however, some positive data. The Registrar-General's Returns contain the heading "alcoholism, delirium tremens," as a cause of death. The following are the rates per million recorded in quinquennial periods from 1870 to 1905: 37·6, 42·4, 48·2, 56·0, 67·8, 85·8, 78·2. This is unsatisfactory for two reasons: the first is, that alcoholism does not nearly cover all the mortality directly caused by drink; and the second is that, being a very vague term, its use in certifying the cause of death depends largely on the views of the practitioner and current opinion in the medical profession. The attention paid to the subject has led to a growing recognition of alcoholism, which, indeed, does not appear at all in the older text-books. This accounts for the steady increase of deaths ascribed to it, which is otherwise inexplicable, being quite at variance with the consumption of drink during the same period. The Seventy-first Annual Report of the Registrar-General states that the mortality from alcoholism in the years 1900 and 1901 was materially increased by the transference of deaths that had been originally certified as from neuritis. It is now usual to classify alcoholism and cirrhosis of the liver together, since the latter is most frequently caused by intemperance. The following are the crude death-rates for twenty years:—

Death-Rates to a Million Living—England and Wales.

	Alcoholism.			Cirrhosis.		
Year.	Male.	Female.	Persons.	Male.	Female.	Persons.
1889	72	39	55	140	103	121
1890	94	50	70	144	105	124
1891	94	49	71	148	104	125
1892	86	49	67	142	104	122
1893	93	55	73	139	103	120
1894	76	47	61	136	96	115
1895	84	51	67	133	104	118
1896	91	52	71	140	106	122
1897	97	58	77	151	115	133
1898	98	59	78	152	112	132
1899	113	69	90	167	119	142
1900	132	95	113	162	127	144
1901	113	80	96	151	115	132
1902	105	65	84	144	104	123
1903	91	62	76	136	100	117
1904	85	55	70	135	101	117
1905	79	52	65	131	104	117
1906	80	53	66	127	98	112
1907	79	48	63	123	101	112
1908	65	45	55	120	88	104

These figures dispose of the current belief in an enormous increase of female intemperance based on the progressive rise of the death-rates. Discussing this question some years ago the present writer pointed out the defects of the statistics and said that the returns of the next few years might upset the whole argument. They have done so.

The statistics of alcoholism and cirrhosis, however, are very far from covering all the mortality due to drink. Dr Newsholme calculates by inference from the returns of Denmark and Switzerland that the deaths directly attributed to alcohol in England and Wales should be some six times higher than they appear in the returns, and that they would then amount to 5 per cent. of the total deaths of adults instead of about 0·8 per cent. He adds: "This percentage probably greatly understates the real facts." It may be so, but the calculation is based on too many assumptions to be accepted with confidence. In addition to the direct mortality there is an unknown score against alcohol in predisposing to other diseases and in accelerating death. Consumption is one of the diseases thought to be particularly associated with alcohol, but there are several others. The following table shows the comparative mortality of males aged 25 to 65 from certain classes of disease in different groups of occupations. They include those with the highest and those with the lowest mortality. The heading "diseases of the circulatory system" includes heart disease and aneurism; diseases of respiratory system include bronchitis, pneumonia and pleurisy, but not phthisis, which is separately given; diseases of urinary system include Bright's disease. The table is compiled from the supplement to the Sixty-fifth Annual Report of the Registrar-General, published 1908. No other country has similar statistics. There are some partial ones for Switzerland, which attribute 2·47 per cent. of the deaths of males over 20 years directly or indirectly to alcohol, and for Denmark, where the corresponding figure is 42 per cent.

The association of a high degree of alcoholic mortality with weakness of all the organs is clearly shown by the figures for unoccupied males, general labourers, dockers, costermongers, innkeepers and inn-servants. Potters and file-makers, with a comparatively low degree of alcoholic mortality, alone show a similar condition, *Comparative Mortality—England and Wales.*

	All Causes.	Alcoholism.	Diseases of Liver.	Phthisis.	Diseases of Nervous System.	Diseases of Circulatory System.	Diseases of Respiratory System.	Diseases of Urinary System.
All males	1,000	16	27	186	105	144	174	52
Occupied and retired males	1,004	16	27	187	103	146	177	52
Unoccupied males	2,884	42	68	583	879	294	310	112
Clergy	524	2	14	55	64	88	53	38
Agriculturists	602	7	13	85	62	96	86	29
Railway engine-drivers	610	4	18	65	74	107	84	36
Civil Service	723	5	40	129	80	102	78	51
Navvies, &c.	740	6	9	95	63	113	154	29
Shopkeepers	872	19	34	161	96	124	139	51
Coal-miners	885	5	17	89	87	134	196	35
Building trades	934	14	21	190	94	134	163	54
Metals	1,027	11	23	189	109	151	213	56
Textiles	1,055	10	21	190	123	165	193	61
Dockers	1,481	50	22	308	112	198	365	64
Potters	1,493	8	21	285	131	219	473	53
Seamen	1,646	26	34	262	170	238	220	83
File-makers	1,700	14	15	387	225	198	325	160
Innkeepers	1,781	111	201	271	188	207	252	127
Inn-servants	1,883	131	49	543	146	211	224	100
Costermongers	2,007	59	40	554	167	276	392	86
General labourers	2,235	40	37	491	233	324	444	96

and it is no doubt due to the inhalation or absorption of irritating or poisonous particles through the nature of their occupation. The clergy, who have the lowest alcoholic mortality, show a remarkably low level of organic disease of all kinds; railway engine-drivers, who come next, suffer more from circulatory and respiratory diseases, navvies and coal-miners still more, while civil servants are more susceptible to phthisis. Agriculturists, though with a higher alcoholic mortality, nearly equal the clergy in general healthiness, which must be attributed to the open-air life. The low alcoholic level of coal-miners and navvies is striking, because both are hard-drinking classes; their position can only be explained by the fact that they drink beer, and it goes far to prove the innocuousness of beer when combined with hard work. The enormous and absurdly disproportionate mortality from diseases of the liver among innkeepers, and in a lesser degree among unoccupied males, is obviously due to a preference for stating that cause on certificates in place of alcoholism. The condition of unoccupied males revealed by this table is worth a volume of sermons. The mortality among them between the ages of 25 and 65 is higher than that of any other class of the community. It is also worth noting that poverty is good for health. The clergy are the poorest of the educated and professional classes; and agricultural labourers, who are the poorest of the manual working classes, are nearly as healthy all round except that they are somewhat more liable to phthisis; their comparative mortality figure from all causes is only 621.

Longevity.—A great deal of statistical information with regard to the comparative longevity or expectation of life at different ages among abstainers and non-abstainers has been collected by life-insurance companies and friendly societies. The following table is given in the syllabus of temperance teaching in elementary schools issued in 1909:—

Expectancy of Life.

Age.	General Expectancy of Total Male Population (Registrar-General).	General Expectancy based on Experience of Insurance Offices.	Odd-fellows.	Rechabites (abstainers).	United Kingdom Temperance Institution (abstainers).
20	41·0	43·2	41·4	48·8	46·9
25	37·0	39·1	37·6	44·3	43·0
30	33·1	35·1	34·0	39·7	38·8
35	29·2	31·2	30·3	35·1	34·6
40	25·6	27·4	26·8	30·6	30·3
45	22·2	23·7	23·3	26·1	26·1
50	18·9	20·1	19·9	21·8	22·0
55	15·8	16·7	16·6	17·7	18·1
60	12·9	13·6	13·6	13·8	14·6

Similar statistics have been prepared showing the relative mortality experience among insured persons. Mr R. M. Moore gives the following proportional figures at different ages for all the societies embraced in the Institute of Actuaries tables, as compared with the abstaining section of the United Kingdom Temperance and Provident Institution, which is taken as 100:—

Mortality Experience of Non-Abstainers to Abstainers as 100.

Age.	Mortality Experience.	Age.	Mortality Experience.
15–19	67	55–59	144
20–24	21	60–64	132
25–29	172	65–69	120
30–34	194	70–74	116
35–39	190	75–79	91
40–44	181	80–84	107
45–49	179	85–89	107
50–54	165	90–94	127

The United Kingdom Temperance Institution has a general as well as an abstaining section. The experience of the twenty-two years 1884–1905 gives the following result: percentage of actual to expected deaths—general section, 79·53; temperance section, 54·25. Other offices having abstaining sections show similar results, thus:—

	General.	Temperance.
Sceptre Life Association (25 years)	79·67	53·05
Scottish Temperance Life Assurance Co. (25 years)	64	46

Pathology.—Dr Sims Woodhead thus summarizes the results of experimental investigation into the direct action of alcohol upon living cells and tissues.

Alcohol plays a prominent part in bringing about degeneration of nerves, muscles and epithelial cells; it determines the accumulation of waste products in the tissues by paralysing the tissue cells, interfering with oxidation, with secretion and with excretion; it induces the proliferation of the lower forms of tissue, often at the expense of the more highly developed tissues, which in its presence undergo marked degenerative changes; it interferes directly with the production of immunity against specific infective diseases, and reasoning from analogy it may be assumed that it plays an equally important part in impairing the resistance of tissue to the advance of the active agents in the production of disease that may have already obtained a foothold in the body.

With regard to this aspect of the subject it must be remembered that laboratory experiments by which alcohol is placed in direct contact with cells and tissues are an entirely different thing from the dietetic use of beverages containing dilute alcohol with other things. It would be interesting to know how the tissues would behave when similarly treated with common salt, lemon juice, vinegar, theine, caffeine or other substances in general dietetic use, or with ordinary tonics such as quinine, quassia and dilute acids.

Inebriety.—Much study has been devoted to inebriety as a diseased condition. It generally results from long-continued and excessive indulgence in alcohol and is characterized by dipsomania or a craving for alcohol, which is chronic or periodical and which the subject cannot resist. It is accompanied by organic changes in the nervous system, which probably begin in the stomach, but end in disintegration of the brain cells with the development of alcoholic insanity. The only chance of cure lies in complete abstinence from liquors with, at first, suitable medical treatment. The recognition of this fact has led to the establishment of special institutions for this purpose, both of a voluntary and a compulsory character. An account of the laws relating to the subject is given under the heading of Inebriety. In accordance with the law three classes of institutions have been established in the United Kingdom:—(1) Certified inebriate reformatories, to which patients are committed by the courts for various periods of detention. They are 11 in number, and during 1908—the last year reported—the committals to them numbered 262 (218 women and 44 men). The total number committed since their establishment in 1897 is 3002 (2548 women and 484 men); the highest number in any one year was 493 (428 women and 65 men) in 1907. (2) State Inebriate Reformatories, more of a penal character, for persons committed but too refractory for the previous class. There are two, one for women and one for men; the average number under detention in 1908 was 74 women and 42 men; the admissions were 27 women and 10 men. (3) Licensed retreats, for voluntary patients. In 1908 they numbered 20, and had under treatment 493 patients (288 women and 205 men). In all about 800 habitual inebriates are thus treated. The results cannot be stated with any precision, but they are certainly disappointing. The Inebriates After-Cure Association gives the following analysis of 407 cases discharged from reformatories and looked after in the years 1903–8:—Satisfactory result, 82 (50 women, 32 men); unsatisfactory, 114 (78 women, 36 men); not known, 221 (162 women, 49 men). One explanation of the failure of treatment and the frequency of relapses which has been revealed by longer and closer study of the problem is that many inebriates are really mental defectives, as already noted in connexion with insanity. Such cases constantly reappear in the police courts after discharge.

Heredity.—It has long been generally assumed that the children of alcoholics suffer in body and mind for the sins of their parents, that they are weak, diseased and defective; and it is very often assumed that they inherit an alcoholic craving. The latter assumption is not admitted by scientific students of the question, but the former has been generally held, though without any proof. It has been made the subject of a statistical investigation (1910) in the Eugenics laboratory of London University by Miss E. M. Elderton and Professor Karl Pearson. The object was to "measure the effect of alcoholism in the parents on the health, physique and intelligence of their offspring," whether by toxic or environmental influence, but not by the transmission of original defective characters, which is omitted from the inquiry. The material used is a report by the Edinburgh Charity Organization Society on the children in one of the Edinburgh schools and one by Miss Mary Dendy on those in the special schools of Manchester. The number of children is not stated, but so far as can be gathered from the tables the Edinburgh inquiry covered about 1000 and the Manchester inquiry about 2000. The ages were from 5 to 14 (Edinburgh report), and both sexes are included in approximately equal numbers. The general conclusion reached is that "no *marked* relation has been found between the intelligence, physique or disease of the offspring and parental alcoholism in any of the categories investigated." The principal particular conclusions reached are as follows:—Higher death-rate in alcoholic than in sober families, more marked in the case of mother than of father, but alcoholic parents more fertile, and therefore nett family about equal; height and weight of alcoholic children slightly greater, but when corrected for age slightly less; general health of alcoholic children slightly better, markedly so in regard to tuberculosis and epilepsy; parental alcoholism not the source of mental defect in children; no perceptible relation between parental alcoholism and filial intelligence.

These conclusions, which run counter to current opinions, have been much criticized, and it is true that the scope of the inquiry is inadequate to establish them as general propositions. Moreover, the chronological relation of parental intemperance to the birth of the children is not stated. But so far as it goes the investigation is sound and it is the first attempt to treat the subject in a scientific way. Nor is there anything in the conclusions to surprise careful and unbiassed observers. The existence of a broad relation between superior vigour and an inclination for alcoholic drinks was pointed out years ago by the writer; drinking peoples are noticeably more energetic and progressive than non-drinking ones. It is the universal experience of shipmasters that British seamen, whose intemperance causes trouble and therefore induces a preference for more sober foreigners, exhibit an energy and endurance in emergency of which the latter are incapable. Similar testimony has repeatedly been borne by engineers and contractors engaged in large works in the south of Europe. And that acute observer, Miss Loane, has related a particular and striking case in regard to offspring from her own experience, which is curiously in keeping with the conclusions of the Eugenics laboratory. The question, however, needs much more elucidation.

The whole subject has, in truth, got somewhat out of perspective. The tendency of the statistical and experimental investigations, summarized above into the relations of alcohol with crime, mortality, disease, &c., has been to obliterate the distinction between the use and abuse of alcohol, between moderate and excessive drinking, and to bring into relief all the evils associated with excess, while ignoring the other side of the question. It is legitimate and desirable to emphasize the evils, but not by the one-sided and fallacious handling of facts. Alcoholic excess produces the evils alleged, though not to the extent alleged, but there is no evidence to show that its moderate use produces any of them. Yet they are all put down to "alcohol," and the inference is freely drawn that its abolition would practically put an end to crime, vice, poverty and disease without any counterbalancing loss whatever. The facts do not warrant that inference, nor has mankind at large ever accepted it. Both the statistical and experimental evidence is full of fallacies, and especially the latter. The pathological investigations on the action of alcohol referred to above elucidate the organic changes which the tissues undergo in the chronic inebriate who is saturated with spirit, but to draw the inference that alcoholic liquors taken in moderation and consumed in the body have any such action is wholly fallacious. In point of fact we know that they have not. But there is more than that. These experiments only take cognizance of alcohol; they ignore the other substances actually consumed along with it. Some of these, and notably sugar, are recognized foods; the balance of opinion on the vexed question whether alcohol itself is a food—which really depends on what is meant by a food—is now on the side of alcohol. But in addition to the principal constituents, easily separable by analysis, are many other substances of which science takes no cognizance at all; they are not identified. They may be in minute quantities yet extremely powerful, as are many other vegetable extractives. We know that they exist by their taste and their effect; they make the difference between port and sherry, between claret and Burgundy, between one vintage and another, between brandy and whisky, differences unknown to chemistry—which only recognizes alcohol, and knows very little about that—but vastly important to the human organism. Another group of experiments are equally fallacious in a different way. The effect of alcohol in mental operations is tested by the comparative speed and ease with which work is done after a dose and without it. The effect has been found to be diminished speed and ease; but these experimenters do not apply the same test to a good meal or a sound sleep or hard exercise. The writer finds in concentrated mental work that the immediate effect of even a small dose of alcohol is to impair efficiency, but the other three do so in a much higher degree. The inference is not that these are injurious, but that the proper time for each is not just before work; after work he finds them all, alcohol included, beneficial. The mortality statistics are treated in a similar one-sided way. They clearly show the injury done by the abuse of alcohol, but what of its moderate use? Agricultural labourers are the most typical moderate drinking class, and they are one of the healthiest in spite of exposure, bad housing and poverty. If all the unhealthiness of those who drink hard is referred to their drink, then the healthiness of those who drink moderately should be referred to it too.

The absolute condemnation of alcoholic drinks has never been endorsed by public opinion or by the medical profession, because it is contradicted by their general experience. That many persons are better without any alcohol, and that many more would be better if they took less than they do is undeniable; but it is equally undeniable that many derive benefit from a moderate amount of it. Sir James Paget, than whom no man was more completely master of his appetites or better qualified to judge, drank port wine himself because he found that it did him good. He represents the attitude of the medical profession as a whole and of temperate men in general. Attempts to support the case for abolishing the use of alcoholic liquors by denying them any value and by attributing to them effects which spring from many other causes, do not carry conviction or advance the cause of temperance. A much stronger argument lies in the difficulty of drawing a definite line between use and abuse; they tend to merge into one another, and it may be urged that the evils of the latter are sufficiently great to justify the abandonment of the former. But the use of most things is open to the same objection, and mankind at large has never consented to forego the gratification of a natural appetite because it is liable to abuse. Nor is there any sign of an intention to make an exception in favour of alcohol. On the other hand, moderation is attainable by every sane individual. It is in fact observed by the great majority and to an increasing extent. There *is* a line between use and abuse, and every one really knows where it is in his own case. If he cannot draw it let him abstain, as Dr Johnson did for that reason. But society can do much to assist the individual by inculcating moderation, setting a standard, promoting its maintenance by helpful environment, discouraging excess and diminishing temptation. All the evidence points to those means as the effective agents in securing the improvement which has taken place in Great Britain.

This article should be read in conjunction with that on LIQUOR LAWS, and it will therefore be in place here to give some additional information regarding the latter. The policy of prohibition has recently gained ground in several countries. In 1910 nine American states had adopted it—namely: Maine, Kansas, N. Dakota, Georgia, Oklahoma, Alabama, Mississippi, N. Carolina and Tennessee; and it was estimated that nearly half the population of the United States were living under state or local prohibition. In Canada the province of Prince Edward Island has adopted complete prohibition. In 1908 Iceland by a popular vote resolved to prohibit the manufacture, importation and sale of intoxicating liquor. In Norway nearly half the towns have adopted prohibition under the law of 1906. In Belgium and Switzerland the manufacture, importation and sale of absinthe was forbidden in 1908. In New Zealand the principle of prohibition has gained ground, and in 1910 was in force over one-seventh of the colony.

TEMPEST, MARIE (1866–), the stage name of the English actress, *née* Marie Susan Etherington, who in 1898 married Cosmo Gordon-Lennox ("Cosmo Stuart"), a grandson of the 5th duke of Richmond, and himself an actor and playwright. She had a charming soprano voice and was educated for the operatic and concert stage, but at first appeared in light comic opera, in which she became very popular. Abandoning music, however, for the comedy stage, she made an even greater success as an actress, notably in *Becky Sharp* (1901); and under her own management in later years she produced a succession of modern comedies, in which her capacity for rivalling in London the triumphs of Réjane in Paris was conspicuously displayed.

TEMPIO PAUSANIA, a town of Sardinia, in the province of Sassari, from which town it is 52 m. E.N.E. by road. It is also reached by rail by a branch line (25 m.) N.W. from the main line from Terranova to Cagliari, leaving the latter at Monti, 14 m. S.W. of Terranova. Pop. (1901) 6511 (town), 14,573 (commune). It lies in a mountainous district 1856 ft. above sea-level, to the N.N.W. of the Monte Limbara. It is the chief town of the Gallura, and has been an episcopal see since the 19th century (with Ampurias). The cathedral is a modern building. The district is agricultural and pastoral. The costumes are picturesque, especially those of the women. For the name Pausania see TERRANOVA PAUSANIA.

TEMPLARS. The Knights Templars, or Poor Knights of Christ and of the Temple of Solomon (*pauperes commilitones Christi templique Salomonici*), formed one of the three great military orders, founded in the 12th century. Unlike the Hospitallers and the Teutonic Knights it was a military order from its very origin. Its founders were a Burgundian knight named Hugues de Payns [1] (Hugo de Paganis) and Godeffroi de St Omer, a knight from northern France, who in 1119 undertook the pious task of protecting the pilgrims who, after the first crusade, flocked to Jerusalem and the other sacred spots in the Holy Land. They were quickly joined by six other knights and soon afterwards organized themselves as a religious community, taking an oath to the patriarch of Jerusalem to guard the public roads, to forsake worldly chivalry, "of which human favour and not Jesus Christ was the cause," and, living in chastity, obedience and poverty, according to the rule of St Benedict, "to fight with a pure mind for the supreme and true King."

To this nascent order of warrior monks Baldwin I., king of Jerusalem, handed over a part of his royal palace lying next to the former mosque of al-Aksa, the so-called "Temple of Solomon," whence they took their name. They had at first no distinctive habit, wearing any old clothes that might be given to them. Nor was their community exclusive. Their primitive rule seems to have enjoined them especially to seek out excommunicated knights, and to admit them, after absolution by the bishop, to their order, and they thus served a useful purpose in at once disciplining and converting the unruly rabble of "rogues and impious men, robbers and committers of sacrilege, murderers, perjurers and adulterers"[2] who streamed to the Holy Land in hope of plunder and salvation. It was this rule which led later to the most important privilege of the order, the immunity from sentences of excommunication pronounced by bishops and parish priests.[3]

This practice, as Prutz points out, might have brought them at once under the suspicion of the Church, and it soon became expedient to obtain the highest sanction for the new order and its rules. In the autumn of 1127 accordingly Hugues de Payns, with certain companions, appeared in Europe, where he was fortunate enough to secure the enthusiastic support of the all-powerful abbot of Clairvaux. Grateful pilgrims had already begun to enrich the order; the *De laude novae militae*, a glowing panegyric of this new and holy conception of knighthood, addressed by Bernard to Hugues de Payns by name, insured the success of his mission. In 1128 the council of Troyes discussed and sanctioned the rule of the order which, if not drawn up by Bernard, was undoubtedly largely inspired by him.[4]

Rule of the Temple.—No MS. of the original French Rule of the Temple (*Règle du Temple*) exists. Of the three extant MSS. representing later recensions, one is preserved at the Accademia dei Lincei at Rome (Cod. 44, A 14), one at the Bibliothèque Nationale (*fonds français* 1977), the third in the departmental archives at Dijon (H. 111). The last of these, probably intended for the use of the master of a subordinate house, is much abbreviated; it dates, however, from the early part of the 13th century, whereas the others are of the end of the century at earliest. In essentials these copies preserve the matter and spirit of the primitive Rule, and they prove that to the end the order was, in principle at least, submitted to the same strict discipline as at the beginning.[5]

The *Règle du Temple* in its final form as we now possess it contains the rules for the constitution and administration of the order; the duties and privileges of the various classes of its personnel; the monastic rules, regulations as to costume and as to religious services; rules for the holding of chapters, and a summary of offences and their punishment; the procedure at the election of a grand master and at receptions into the order; a definition of the relations of the order to the pope, and to other religious orders. It must be borne in mind, however, that the organization of the order as described below was only gradually developed, not having been fixed at Troyes. At first the master of the Temple at Jerusalem was only one among many; the seneschal and marshal appear not to have existed; and it was not till the bull *Omne datum optimum* of Pope Alexander III. (1163), the great charter of the order, that its organization was definitively centralized.

Constitution.—As finally constituted, the order consisted of (1) knights (*fratres milites*), (2) chaplains (*fratres capellani*), (3) serjeants or esquires (*fratres servientes armigeri*), (4) menials and craftsmen (*fratres servientes famuli* and *officii*). All were bound by the rules of the order and enjoyed its privileges. Women were not admitted to the order.[6]

1. At the head of the order was the master of the Temple at Jerusalem (in Cyprus after the fall of the Latin Kingdom), known as the grand master. His authority was very great—except in certain reserved cases his word was law—but he was not absolute. Thus in matters of special importance—alienation of the estates of the order, attack on a fortress, declaration of war, conclusion of an armistice, reception of a new brother—he had to consult the chapter, and was bound by the vote of the majority; nor could he modify or abrogate a decree of the council of the order without their consent. He had to obtain the consent of the chapter also to the nomination of the grand commanders of the provinces of the order; the lesser offices were absolutely in his gift. He was elected by a complicated process, a chapter summoned *ad hoc* electing a "commander of the election" and one other brother who, after vigil and prayer, co-opted two more, these four choosing another two, and so on till the number of the twelve apostles had been reached. A chaplain, representing Jesus Christ, was then added to complete the electoral college (see Curzon, *Règle du Temple*, p. xxxv).[7]

The grand master was allowed four horses for his ordinary use. His household consisted of a *frater capellanus*, a cleric, a *frater serviens* with two horses, a Saracen secretary (*écrivain sarrazinois*)

[1] A fief in Champagne, near Troyes.

[2] Bernard of Clairvaux, *De laude novae militae*, cap. v. (in Migne, *Patrol. lat.* 182, p. 928).

[3] Prutz, *Templerherrenorden*, p. 12. The Latin copy of the Rule (Bibliothèque Nationale) reads "*Milites non excommunicatos*" for "*chevaliers escomenies*"; which means, according to Prutz, that when the Latin version was made the original significance of the rule had been forgotten. M. de Curzon (*Règle du Temple*, p. iv.), on the other hand, assumes that the Latin text represents the original rules drawn up in 1128 and that the French version is a corrupt copy. That Prutz is right would seem to be shown not only by the reasonableness of the rule in itself (why should the Templars be instructed to look out for gatherings of *non*-excommunicated knights?) but by the language of cap. v. of the *De laude novae militae*, in which Bernard extols the knights for turning the enemies of Christ into his soldiers (*ut quos diu pertulit oppugnatores magis jam propugnatores habere incipiat; faciatque de hoste militem*).

[4] Bernard was not present at the council. But the "humble escrivain" of the Règle du Temple, Johan Michiel, writes "*par le comandement dou concile et dou venerable pere Bernart abbés de Clerevaus.*" Compare the rule also with the chapter (iii.) of the *De laude: De militibus Christi.*

[5] Of a secret Rule, in spite of the most diligent research, no trace has ever been found. It is now generally held that none ever existed. The legend of its existence, so fatal to the order, is probably traceable to the fact that the complete Rule was jealously guarded by the chief office-bearers of the order, only excerpts being given to the heads of the lesser houses (*e.g.* the Dijon MS.) and known generally to the knights.

[6] Rule 70. *Perillouse chose est compaignie de feme, que le deable ancien par compaignie de feme a degeté pluisors dou droit sentier de paradis.* It is interesting to compare this with the more wholesome view of the best of the contemporary chivalrous poets, *e.g.* Walther von der Vogelweide or Wolfram von Eschenbach (*Parzival*), who hold up true love as the highest earthly incentive to noble deeds.

[7] The bull *Omne datum optimum* (1163) decreed that the master must be a knight of the order who had taken the vows, and vested the election exclusively in the knights.

as interpreter, a *turcople, i.e.* a soldier belonging to the light-horse attached to the order, a farrier and a cook, two footmen (*garçons à pied*) to look after his special Turcoman horse, only used in war time. He was further attended by two knights of the order of high rank. The ensigns of his presence on campaign were the large round tent and the *gonfanon baucent*, the black and white pennant, charged with the red cross of the order.

2. The second officer of the Temple was the *seneschal.* He had a right to attend all chapters, even the most secret. His equipage, tent, banner and seal were the same as the master's. Attached to his person were two squires, a knight companion, a *frater serviens*, a secretary in deacon's orders to say the hours, a *turcople*, a Saracen secretary and two foot servants.

3. Third in order was the *marshal*, who was supreme military authority, and had under his charge the horses and arms. In the absence of master and seneschal he acted as *locum tenens.* His equipage and *suite* were much the same as those of master and seneschal.

The provincial marshals were absolute in their provinces, but subordinate to the marshal of the order.

The commander of the land and realm of Jerusalem was grand treasurer of the order, administered its estates in the province of Jerusalem, and was responsible for the lodging of the brethren. He also had charge of the fleet, the commander of the port of Acre being his subordinate. His equipage and suite were much the same as those of seneschal and marshal.

The commander of the city of Jerusalem was the hospitaller of the order. He was charged with the defence of pilgrims visiting the Holy Land, and with the duty of supplying them with food and horses. Ten knights were specially attached to him for this purpose, and to act as guard to the relics of the True Cross. Subordinate to him was a second commander for the city itself.

The commanders of Tripoli and Antioch enjoyed all the rights of the grand master within their provinces, except when he was present. They too had the round tent and the *gonfanon.*

Besides these, the rule mentions the commanders of France, England, Poitou, Portugal, Apulia and Hungary, whose rights and privileges are analogous to those of the commanders above mentioned.[1]

Lastly, of the great officers of the order must be mentioned the *drapier*, who was charged with the supervision of the clothing of the brethren. He was closely associated with the commander of the kingdom of Jerusalem, his equipage was that of the commanders, but his suite included a number of tailors.

Below the great dignitaries there were in the provinces *commanders of houses*, under the provincial commanders, and the *commanders of the knights*, who acted as lieutenants of the marshals.

Turning to the general body of the order: the knights (*milites*) were entitled to three horses and a squire, or by special favour to four horses and two squires. They had two tents.

Of the serjeants (*servientes*) five occupied an exceptional position: the deputy-marshals (*souz-mareschau*), who looked after the arms and armour, the *gonfanonier*, who was responsible for the discipline and catering of the squires, the *kitchener* (*cuisinier*) and the *farrier.* These had two horses, a squire and a tent. All the others, even if commanders of houses, had but one horse. At the head of all the serjeants in time of war was the *turcoplier*, the chief of the *turcoples.* He had four horses in his equipage and certain special prerogatives; in battle he took his orders only from the master or seneschal.

Of peculiar importance were the *chaplains* (*fratres capellani*). These did not originally form part of the order, which was served by priests from outside. The bull *Omne datum optimum* of 1163 imposed on clerics attaching themselves to the order an oath of life-long obedience to the grand master; by the middle of the 13th century the chaplains took the same oath as the other brothers and were distinguished from them only by their orders and the privileges these implied (*e.g.* they were spared the more humiliating punishments, shaved the face, and had a separate cup to drink out of). The order thus had its own clergy, exempt from the jurisdiction of diocesan bishops and parish priests, owing obedience to the grand master and the pope alone. By the rules, no Templar was allowed to confess to any save a priest attached to the order, if one were available, and such priest was formally declared to have received from the pope more power to absolve than an archbishop.[2]

It remains to be said that the brethren were admitted either for life or for a term of years. Married men were also received, but on condition of bequeathing one half of their property to the order (rule 69).

The chapters of the order were either secret, composed of such brothers as the master might esteem "wise and profitable for giving advice," or general assemblies of the order, at the discretion of the master, who was to listen to the counsel given and do what seemed best to him (rule 36).

Habit of the Order.—The characteristic habit of the order was the white mantle, symbolic of purity, with the red cross, the ensign of the champions of the Church, first granted by Pope Eugenius III. (1145–53). Only the unmarried knights bound by life-long vows, however, were privileged to wear the white mantle, which was also given to chaplains in episcopal orders. The rest wore a black or brown mantle, the red cross being common to all. The chaplains were distinguished by wearing the mantle closed.

Conduct and Discipline.—The brethren were to attend daily services; but the soldier outwearied with his nightly duties might on certain conditions absent himself from matins with the master's consent. Two regular meals were allowed for each day; but to these might be added, at the master's discretion, a light collation towards sunset. Meat might be eaten thrice a week; and on other days there was to be a choice of vegetable fare so as to suit the tenderest stomach. Brethren were to eat by couples, each keeping an eye on his fellow to see that he did not practise an undue austerity. Wine was served at every meal, and at those times silence was strictly enjoined that the words of Holy Writ might be heard with the closest attention.[3] Special care was to be taken of aged and ailing members. Every brother owed the most absolute obedience to the master of the order, and was to go wherever his superior bade him without delay, "as if commanded by God." All undue display in arms or harness was forbidden. Parti-coloured garments were forbidden. All garments were to be made of wool; but from Easter to All Souls a linen shirt might be substituted for one of wool. The hair was to be worn short, and a rough beard became one of the distinguishing marks of the order. Hunting and hawking were unlawful; and the very allusion to the follies or secular achievements of earlier life was forbidden. A lion, however, being the type of the evil one, was legitimate prey. Strict watch was kept on the incomings and outgoings of every brother, except when he went out by night to visit the Sepulchre of our Lord. No letter, even from the nearest relative, might be opened except in the master's presence; nor was any member to feel annoyance if he saw his relative's gift transferred at the master's bidding to some other brother. The brethren were to sleep in separate beds in shirts and breeches, with a light always burning in the dormitory. Those who lacked a mattress might place a piece of carpet on the floor; but all luxury was discouraged.

A term of probation was assigned to each candidate before admission; and a special clause discouraged the reception of boys before they were of an age to bear arms.[4] Lastly, the brethren of the Temple were exhorted to shun the kiss of every woman, whether maid or widow, mother, aunt or sister.

For grievous offences, such as desertion to the Saracens, heresy, losing the gonfalon, murdering a Christian, or failing to account for all the property of the order in his possession, a Templar might be expelled (*perdre la maison*); for minor offences, such as disobedience, lowering the banner in battle, or killing a slave or a horse, he suffered a temporary degradation (*perdre son abit*). No member of another religious order was received by the Templars, and no Templar could leave the order without permission of the master, and then only on condition of joining a stricter monastic community. By mutual agreement the Templars and Hospitallers, despite their long and deadly feud, were bound not to receive ejected members of the rival order; and the Templar cut off in battle and defeat from all hope of rejoining his own ranks might rally to the cross of St John.

History.—Long before St Bernard's death (1153) the new order was established in almost every kingdom of Latin Christendom. Henry I. granted them lands in Normandy. They seemed to have been settled in Castile by 1129, in Rochelle by 1131, in Languedoc by 1136, at Rome by 1138, in Brittany by 1141, and in Germany at perhaps a still earlier date. Alphonso I. of Aragon and Navarre, if we may trust the Spanish historians, bequeathed them the third of his kingdom (Mariana, x. c. 9). Raymond Berengar IV., count of Barcelona, and Alphonso's successor in Aragon, whose father had been admitted to the order, granted them the strong castle of Monzon (1143), and established a new chivalry in imitation of theirs. Louis VII. in the latter years of his reign gave them a piece of marsh land outside Paris, which in later times became known as the Temple, and was the headquarters

Spread of the order.

[1] The titles varied. The provincial commander is "Master" or "Grand Prior" or "Grand Preceptor" under him are "priors" over large estates, and under them "preceptors" of houses. Preceptors took their name from the mandate of the master issued to them: "*Praecipimus tibi.*"

[2] Rule 269 . . . *Car il en ont greignor povir de l'apostoile* (*i.e.* the pope) *d'eaus assoudre que un arcevesque* (Curzon, p. 165).

[3] The Bible was read in a French translation. A MS. of a Templar Bible, exhibiting curious touches of the critical spirit, is now in the Bibliothèque Nationale in Paris. See Prutz, *Templerherrenorden*, p. 116.

[4] This rule was not observed later on, postulants being admitted without any period of noviciate, and among the Templars arrested in 1307 were many young boys.

of the order in Europe.[1] Stephen of England granted them the manors of Cressing and Witham in Essex, and his wife Matilda that of Cowley, near Oxford. Eugenius III., Louis VII., and 130 brethren were present at the Paris chapter (1147) when Bernard de Balliol granted the order 15 librates of land near Hitchin; and the list of English benefactors under Stephen and Henry II. includes the noble names of Ferrers, Harcourt, Hastings, Lacy, Clare, Vere and Mowbray. Spiritual privileges were granted to them by the popes as lavishly as temporal possessions by the princes and people. Pope Adrian IV. allowed them to have their own churches; Eugenius III. added to these the right to have churchyards; and churches and churchyards, as in the case of the order generally, were exempted from the operation of ordinary excommunications and interdicts. Thus a person dying excommunicated, refused burial elsewhere, sometimes—like Geoffrey de Mandeville[2]—found a resting-place in the consecrated ground of the Templars. Eugenius III. also granted the Templars the right to have interdicted churches opened twice a year for the purpose of making their collections. They were, moreover, as defenders of the Church, exempted from the payment of tithes. Finally, they were exempted from the action even of general censures and decrees of the popes, unless mentioned in them by name. Very soon the order refused to submit in any way to the ordinary jurisdiction of the diocesan bishops and formed in effect a separate ecclesiastical organization under the pope as supreme bishop. The result was that, scarce twenty-five years after its foundation, the order was at open feud with bishops and parish priests, and the popes found it necessary to issue decree after decree to protect it from violence and spoliation. The complaints of the secular clergy, on the other hand, came to a head in 1179 at the Lateran Council, when even Pope Alexander III. had to consent to a series of decrees directed against the abuse of its privileges by the order (Prutz, p. 41).

So long, however, as the attention of the papacy and of Christendom was fixed on the problem of recovering and safeguarding the Holy Land, the position of the Templars was unassailable, and all efforts to curb the growth of their power vain. The order as such had no European policy;[3] the whole of its vast organization was maintained for the purpose of feeding the holy war against the infidels with recruits and with money; and its ultimate fate depended on its success or failure in the East. (W. A. P.)

After the council of Troyes Hugues de Payns came to England and induced a number of knights to follow him to the Holy Land. Among these was Fulk, count of Anjou, who would thus seem to have been a Templar before assuming the crown of Jerusalem in 1131. Hugues de Payns died about the year 1136 and was succeeded by Robert de Craon, who is said to have been Anselm's nephew. Everard de Barris, the third master, was conspicuous in the second crusade. In the disastrous march from Laodicea to Attalia his troops alone kept up even the show of discipline; and their success prompted Louis VII. to regulate his whole army after the model of the Templar knights. In the French king's distress for money the Templars lent him large sums, ranging from 2000 silver marks to 30,000 solidi. When Conrad III. of Germany reached Jerusalem he was entertained at their palace (Easter 1148); and in the summer of the same year they took part in the unsuccessful siege of Damascus. The failure of this expedition was ascribed by a contemporary writer to their treachery—a charge to which Conrad would not assent. This is the first note of the accusations which from this time were of constant recurrence.[4]

Early grand masters.

Henceforward for 140 years the history of the Templars is the history of the CRUSADES (*q.v.*). In 1149 the Templars were appointed to guard the fortress of Gaza, the last Christian stronghold on the way towards Egypt. Four years later the new master, Bernard de Tremelai, and forty of his followers, bursting into Ascalon, were surrounded by the Saracens and cut off to a single man. William of Tyre has preserved the scandal of the day when he hints that they met a merited fate in their eagerness to possess themselves of the city treasure. Next year the rumour went abroad that they had sold a noble half-converted Egyptian prince, who had fallen into their hands, to chains and certain death for 60,000 aurei. In 1166 Amalric, the Latin king of Jerusalem, hanged twelve Templars on a charge of betraying a fortress beyond the Jordan to an amir of Nūr al-Dīn of Damascus. The military power of Nūr al-Dīn (1145–73) was a standing menace to the Christian settlements in the East. Edessa had fallen to the prowess of his father (1144–45); Damascus was conquered by the son (1153), who four years earlier had carried his depredations almost to the walls of Antioch, and in 1157 laid siege to the Christian town of Paneas near the sources of the Jordan. In the disastrous fight that followed for the safety of the fortress of the Hospitallers, Bertrand de Blanquefort, the master of the Templars, and Odo de St Amand, one of his successors, were taken prisoners. Bertrand was released later when Manuel was preparing to march against Nūr al-Dīn. The Templars do not seem to have opposed Amalric's early expeditions against Egypt. It was Geoffrey Fulcher, the Templar correspondent of Louis VII., who brought back (1167) to Jerusalem the glowing accounts of the splendour of the caliph's court at Cairo with which Gibbon has enlivened his great work. Nor was the order less active at the northern limits of the Latin kingdom. Two English Templars, Gilbert de Lacy and Robert Mansel, "qui Galensibus praeerat," starting from Antioch, surprised Nūr al-Dīn in the neighbourhood of Tripoli and put him barefooted to flight. But jealousy or honour led the Templars to oppose Amalric's Egyptian expedition of 1168; and the wisdom of their advice became apparent when the renewed discord on the Nile led to the conquest of Egypt by Asad al-Dīn Shīrkūh, and thus indirectly to the accession of Saladin, in 1169. In 1170 they beat Saladin back from their frontier fortress of Gaza; and seven years later they shared in Baldwin IV.'s great victory at Ascalon.

Relations with Nūr al-Dīn.

Relations with Saladin.

Meanwhile Saladin had possessed himself of Emesa and Damascus (1174–75), and, as he was already lord of Egypt, his power hemmed in the Latin kingdom on every side. In July 1173 Amalric was succeeded by his son Baldwin IV., a boy of twelve. Raymond III., count of Tripoli, a man suspected of being in league with the Saracens, was appointed regent, although in 1176 the masters of the Templars and the Hospitallers united in offering this office to the newly arrived Philip of Flanders. The construction of the Templar fortress at Jacob's ford on the upper Jordan led to a fresh Saracen invasion and the disastrous battle of Paneas (1179), from which the young king and the Holy Cross escaped with difficulty, while Odo de St Amand, the grand master, was carried away captive and never returned.

During Odo's mastership the Old Man of the Mountains sent to Amalric offering to accept the Christian faith if released from the tribute he had paid to the Templars since (according to the

[1] In August 1279, Philip IV. ceded to the Templars within the precincts of the Temple at Paris (*vicus Templi*), *i.e.* the whole fortified quarter on the right bank of the Seine, the right to exercise higher and lower justice (*alta et bassa justicia*), to retain all property usually escheated to the crown, and to guard their fortress "night and day" by means of their own *servientes* without interference. The king undertook, for himself and his successors, not to endeavour to levy any *taille* or other tax nor to exact any of the customary feudal services within the Temple. Text in Prutz, *Templerherrenorden*, p. 298.

[2] Illo autem, in discrimine mortis, ultimum trahente spiritum, quidam supervenere Templarii qui religionis sacre habitum cruce rubea signatum ei imposuerunt (*Mon. Ang.*, iv. 142). There must be a slight error here on the part of the chronicler; for Geoffrey died in 1144 and the red cross was not granted to the Templars until the following year. This does not, however, affect the main fact that Geoffrey, though excommunicated, was buried in consecrated ground at the New Temple in London. This was in 1163, twenty-two years before the consecration of the Temple Church now standing. See Round, *Geoffrey de Mandeville*, p. 224.

[3] Finke, p. 42. Individual Templars, of course, acted from time to time as diplomats or as royal advisers; but they in no sense represented the order.

[4] *Hist. Pontific.*, ap. Pertz, xx. 535–536.

reckoning of M. Defrémery) somewhere about 1149. The Templars murdered the envoys on their return (*c.* 1172). Amalric demanded that the offenders should be given up to justice. Odo refused to yield the chief culprit, though he was well known, and invoked the protection of the pope. Amalric had to vindicate his right by force of arms at Sidon, and died while preparing to take stronger measures. The connexion between the Templars and the Old Man was still vital eighty years later when the two grand masters rebuked the insolence of the Assassin envoys in the presence of Louis IX. Odo de St Amand was succeeded by Arnold de Torroge, who died at Verona on his way to implore European succour for the Holy Land. The power of Saladin was now (1184) increasing daily; Baldwin IV. was a leper, and his realm was a prey to rival factions. There were two claimants for the guardianship of the state—Raymond III. of Tripoli and Guy de Lusignan, who in 1180 had married Sibylla, sister of the young king. Baldwin inclined to the former, against the patriarch and Arnold de Torroge.

There is something Homeric in the story of the fall of the Latin kingdom as related by the historians of the next century.

Fall of Latin kingdom.

A French knight, Gerard de Riderfort or Bideford, coming to the East in quest of fortune, attached himself to the service of Raymond of Tripoli, looking for the hand of some wealthy widow in reward. But on his claiming the hand of the lady of Botron he was met with a refusal. Angered at this, Gerard enrolled himself among the Templars, biding his time for revenge, and was elected grand master on the death of Arnold. Baldwin IV. died (1185), leaving the throne to his young nephew Baldwin V., the son of Sibylla, under the guardianship of Raymond, whose office was not of long duration, as the little king died in September 1186. This was Gerard's opportunity. The Templars carried the body of their dead sovereign to Jerusalem for burial; and then, unknown to the barons of the realm, Gerard and the patriarch crowned Sibylla and her husband Guy. The coronation of Guy was the triumph of Raynald of Châtillon, once prince of Antioch, and Saladin's deadliest foe. It was at the same time the overthrow of Raymond's ambition; and both Latin and Arabic writers are agreed that the Christian count and the Mahommedan sultan now entered into an alliance. To break this friendship and so save the kingdom, the two grand masters were sent north to make terms with Raymond. But the rash valour of the Templars provoked a hopeless contest with 7000 Saracens. The grand master of the Hospitallers was slain; but Gerard made his escape with three knights to Nazareth (1st May 1187). In this emergency Raymond became reconciled with Guy; and Gerard placed the Temple treasures of Henry II. at his king's disposal. Once more it was the Templars' rashness that led to the disastrous battle of Hittin (4th July). Gerard and the king fell into the hands of Saladin, but were released about a year later; Raymond of Tripoli made his escape through treachery or fortune; and 230 Templars fell in or after the battle, for the fight was scarcely over before Saladin ordered all the Templars and Hospitallers to be murdered in cold blood. One after another the Christian fortresses of Palestine fell into the hands of Saladin. Jerusalem

Fall of Jerusalem.

surrendered on 2nd-3rd October 1187, and the treasures of the Temple coffers were used to purchase the redemption of the poorer Christians, part of whom the Templar warriors guarded on their sad march from the Holy City to Tripoli. Part of their wealth was expended by Conrad of Montferrat in the defence of Tyre; but, when this prince refused to admit Guy to his city, both the Templars and the Hospitallers from the neighbouring parts flocked to the banner

Siege of Acre.

of their released king and accompanied him to the siege of Acre (22nd August 1189). In his company they bore their part in the two years' siege and the terrible famine of 1190–91; and their grand master died in the great battle of 4th October 1189, refusing to survive the slaughter of his brethren.

On the fall of Acre Philip Augustus established himself in the palace of the Templars, who are, however, stated to have sympathized with Richard. This king sold them the island of Cyprus for 100,000 besants; but, unable to pay the purchase money, they transferred the debt and the principality to Guy of Lusignan. The English king consulted them before deciding on any great military movement; and in June 1192 they advocated the bold plan of an advance on Egypt rather than on Jerusalem. In the disputes for the Latin kingdom of the East the Templars seem to have supported Guy, and, like Richard, were credited with having had a hand in the murder of Conrad of Montferrat (April 1192). It was in the disguise of a Templar and in a Templar galley that Richard left the Holy Land. When Acre was recovered, the Templars, like the Hospitallers, received their own quarters in the town, which from this time became the centre of the order. On the death of Henry of Champagne (1197) they vetoed the election of Raoul de Tabarie; after the death of his successor Amalric they refused to renew the truce with Saladin's brother, Saif al-Dīn, and led an expedition against the Saracens before the arrival of the new king, John de Brienne, at whose coronation in

John de Brienne.

1210 William de Chartres, the grand master, was present. Seven years later, with the aid of Walter de Avennis and of the Teutonic Knights, they commenced the building of their fortress of Castle Pilgrim, near Acre, on a rocky promontory washed by the Mediterranean on every side except the east. This wonderful structure, whose ruins are still to be seen, was fortified with a strong wall, founded on the substructure of a yet more extensive one running from sea to sea, and was flanked by lofty towers of huge squared stones. Within was a spring of pure water, besides fishponds, salt-mines, woods, pastures, orchards, and all things fitted to furnish an abode in which the Templars might await the day of their restoration to Jerusalem.

It was from this castle that in May 1218 the fifth crusade started for the expedition against Egypt. The Templars were the heroes of the siege of Damietta, at which William

Fifth crusade.

de Chartres was slain. "First to attack and last to retreat," they saved the Christian army from annihilation on 29th August 1219; and when the city surrendered (5th November) the only one of its twenty-eight towers that had begun to give way had been shaken by their engines. On the other hand, it was largely owing to their objections that John de Brienne refused the sultan's offer to restore Jerusalem and Palestine.

From the very first the Templars seem to have been opposed to Frederick II., and when he landed at Acre (7th September 1228) they refused to march under the banners of an excommunicated man, and would only accompany his host from Acre to Joppa in a separate body. They were accused of notifying Frederick's intended pilgrimage to the Jordan to the sultan, and they were certainly opposed to Frederick's ten years' peace with Al-Kāmil, the sultan of Egypt, and refused to be present at his coronation in Jerusalem. Frederick was not slow to avenge himself: he left Jerusalem abruptly, publicly insulted the grand master, demanded the surrender of their fortresses, and even laid siege to Castle Pilgrim. He left Acre on the 3rd of May 1229, and on landing in Apulia gave orders to seize the estates of the order and chase all its members from the land.

Long before the expiration of Frederick's peace Europe was preparing for a fresh crusade against the now divided realm of the Ayyubids. Theobald of Navarre and his crusaders

Seventh crusade.

reached Palestine about August 1239. The Templars shared in the great defeat near Jaffa, an engagement which their temerity had done much to provoke (13th November 1239). If the king ever accepted the overtures of Ṣāliḥ of Damascus, he was supporting the policy of Hermann of Perigord, the grand master, who towards the summer of 1244 wrote a triumphant letter to England, telling how he had engaged this sultan and Nāsir of Kerak to make an alliance against the sultan of Egypt and restore the whole of Palestine from the Jordan to the sea. Theobald, however, before leaving the Holy Land (27th September 1240), signed a ten years' truce with Ṣāliḥ of Egypt. The Hospitallers seem to have been won over to his view, and when Richard of Cornwall arrived (11th October) he had to decide between the two rival orders and their opposing policies. After some hesitation he concluded a treaty with the sultan of Egypt, much to the annoyance of the Templars, who openly mocked his efforts. On his departure the three orders came to open discord: the Templars laid siege to the Hospitallers in Acre and drove out the Teutonic Knights "in contumeliam imperatoris." They were successful on all sides. The negotiations with Damascus and Kerak were reopened, and in 1244 Hermann of Perigord wrote to the princes of Europe that after a "silence of fifty-six years the divine mysteries would once more be celebrated in the Holy City."

Kharizmian invasion.

It was in this moment of danger that the sultan of Babylon called in the barbarous Kharizmians, whom the Mongol invasions had driven from their native lands. These savages, entering from the north, flowed like a tide past the newly built and impregnable Templar fortress of Safed, swept down on Jerusalem, and annihilated the Christian army near Gaza on St Luke's day (18th October) 1244. From this blow the Latin kingdom of the East never recovered; 600 knights took part in the battle; the whole force of the Templars, 300 in number, was present, but only 18 survived, and of 200 Hospitallers only 16. The masters of both orders were slain or taken prisoners. Despite the admirable valour of the Templars, their policy had proved the ruin of the land. Jerusalem was lost to Christendom for ever; and, though the Kharizmians melted away in the course of the next three years, they left the country so weak that all the acquisitions of Theobald and Richard fell an easy prey to the sultan of Babylon.

Louis IX.'s crusade.

Recognizing the fact that the true way to Jerusalem lay through Egypt, Louis IX. led his host to the banks of the Nile, being accompanied by the Templars. Their master, William de Sonnac, attempted in vain to restrain the rash advance of the count of Artois at the battle of Mansura (8th February 1250), which only three Templars survived. St Louis, when captured a few weeks later, owed his speedy release to the generosity with which the order advanced his ransom-money. Shortly after his departure from Acre (April 1254) they consented to an eleven years' truce with the sultans of Egypt and Damascus.

Successes of Bibars.

A new enemy was now threatening Mahommedan and Christian alike. For a time the Mongol advance may have been welcomed by the Christian cities, as one after another the Mahommedan principalities of the north fell before the new invaders. But this new danger stimulated the energies of Egypt, which under the Mameluke Bibars encroached year after year on the scanty remains of the Latin kingdom. The great Frankish lords, fearing that all was lost, made haste to sell their lands to the Templars and Hospitallers before quitting Palestine for ever. In 1260 the former purchased Sidon and Beaufort; next year the Hospitallers purchased Arsuf. In 1267, by a skilful adaptation of the banners of both orders, Bibars nearly surprised Antioch. The Templar fortress of Safed surrendered with its garrison of 600 knights, all of whom preferred death to apostasy (June 1266). Beaufort fell in 1268, Antioch six weeks later; and, though the two orders still made occasional brilliant dashes from their Acre stronghold, such as that to Ascalon in 1264 and that with Prince Edward of England to destroy Ḳāḳūn in 1271, they became so enfeebled as to welcome the treaty which secured them the plain of Acre and a free road to Nazareth as the result of the English crusade of 1272.

But, though weak against external foes, the Templars were strong enough for internal warfare. In 1277 they espoused the quarrel of the bishop of Tripoli, formerly a member of the order, against his nephew Bohemond, prince of Antioch and Tripoli, and began a war which lasted three years. In 1276 their conduct drove Hugh III., king of Cyprus and Jerusalem, from Acre to Tyre. In the ensuing year, when Mary of Antioch had sold her claim to the crown to Charles of Anjou, they welcomed this prince's lieutenant to Acre and succeeded for the moment in forcing the knights of that city to do homage to the new king. Thirteen years later (26th April 1290) Tripoli fell, and next year Acre, after a siege of six weeks, at the close of which (16th May) William de Beaujeu, the grand master, was slain. The few surviving Templars elected a new master, and, forcing their way to the seashore, sailed for Cyprus, which now became the headquarters of the order. A futile attempt against Alexandria in 1300 and an unsuccessful effort to form a new settlement at Tortosa about the same time (1300–2) are the closing acts of their long career in the western parts of Asia.

Abandonment of Palestine.

Power and influence of the order.

For more than a hundred years the Templars had been one of the wealthiest and most influential factors in European politics. If we confine our attention to the East, we realize but a small part of their enormous power. Two Templars were appointed guardians of the disputed castles on the betrothal of Prince Henry of England and the French princess in 1161. Other Templars were almoners of Henry III. of England and of Philip IV. of France. One grand master was godfather to a daughter of Louis IX.; another, despite the prohibition of the order, is said to have been godfather to a child of Philip IV. They were summoned to the great councils of the Church, such as the Lateran of 1215 and the Lyons council of 1274. Frederick II.'s persecution of their order was one of the main causes of his excommunication in 1239; and his last will enjoined the restoration of their estates. Their property was scattered over every country of Christendom, from Denmark to Spain, from Ireland to Cyprus. Before the middle of the 13th century Matthew Paris reckons their manors at 9000, Alberic of Trois-Fontaines at 7050, whereas the rival order of St John had barely half the latter number. Some fifty years earlier their income from Armenia alone was 20,000 besants. Both in Paris and in London their houses were used as strongholds for the royal treasure. In the Temple in London Hubert de Burgh and the Poitevin favourites of Henry III. stored their wealth; and the same building was used as a bank into which the debtors of the foreign usurers paid their dues. From the English Templars Henry III. borrowed the purchase money of Oléron in 1235; from the French Templars Philip IV. exacted the dowry of his daughter Isabella on her marriage with Edward II. To Louis IX. they lent a great part of his ransom, and to Edward I. of England no less than 25,000 *livres Tournois*, of which they remitted four-fifths. Jacques de Molay, the last grand master, came to France in 1306 with 150,000 gold florins and ten horse-loads of silver.[1] In the Spanish peninsula they occupied a peculiar position, and more than one king of Aragon is said to have been brought up under their discipline.[2]

[1] The wealth of the Templars was due not so much to their territorial possessions as to the fact that they were the great international financiers and bankers of the age. The Paris Temple was the centre of the world's money market. In it popes and kings deposited their revenues, and these vast sums were not hoarded but issued as loans on adequate security. Above all, it was the Templars who made the exchange of money with the East possible. It is easy, indeed, to see how they were the ideal bankers of the age; their strongholds were scattered from Armenia to Ireland, their military power and strict discipline ensured the safe transmission of treasure, while their reputation as monks guaranteed their integrity. Thus they became the predecessors, and later the rivals, of the great Italian banking companies. See L. Delisle, "Mémoire sur les opérations financières des Templiers" in *Mémoires de l'Institut national de France*, t. xxxii. To take interest (usury) was of course unlawful. The method of circumventing this seems to have been that the mortgages paid to the mortgagors a *nominal* rent which was used towards the reduction of the debt. The difference between this and the *real* rent represented the interest. See *Ancient Charters*, Pt. i. (Pipe Roll Soc., London, 1888), edited by J. H. Round, p. 94 note. A document throwing a vivid light on the banking methods of the Templars and Hospitallers is a charter of Margaret, queen of the English, A.D. 1186, from the abbey of Fontevrault, printed in *Calendar of Documents, France* (London, 1899), vol. i., ed. J. H. Round, No. 1084. (W. A. P.)

[2] The Templars in Aragon and the other kingdoms of the Spanish peninsula were far more subordinate to the crown than elsewhere. None but natives were admitted to their ranks, and there were very few exchanges of knights with foreign commanderies. They were

Such were the power and wealth of the Templars at the time when Philip IV. of France accused them of heresy and worse offences, had them arrested (13th October 1307), and forced them to confess by tortures of the most excruciating kinds. Five years later (26th May 1312) the order was suppressed by decree of the council of Vienne and its goods transferred to the hospital of St John. (T. A. A.)

Suppression of the order.

Never had the order of the Temple been to all appearance more powerful than immediately before its ruin. Sovereign power, in the sense of that of the Teutonic Knights in Prussia or the Knights of St John in Rhodes and later in Malta, it had never possessed; but its privileges and immunities constituted it a church within the church and—in France at least—a state within the state. Philip IV., indeed, in pursuance of his policy of centralizing power in the crown, had from 1287 onwards made tentative efforts to curtail the power and wealth of the order; in 1287 he commanded the sequestration of all its property acquired since the confirmation of its privileges by Louis IX. in 1258; in 1289 the ordinance of Ferrières in Gâtinais was directed against its illegal acquisitions and its interference with the jurisdiction of the king and his vassals; in 1290 the parlement decided that the privileges of the order could only be enjoyed by those who actually wore its habit. Soon, however, the king's necessities forced him to change his policy. In January 1293 the privileges of the order in and about Paris were confirmed and extended, and in 1297 Philip borrowed 5200 *livres tournoises* from the Paris Temple. Then came the great quarrel with Pope Boniface VIII., and on the 10th of August 1303 the king signed with Hugues de Peraud, the general visitor of the French Templars, a formal treaty of alliance against the pope. On the 6th of February 1304 Boniface's successor, Benedict XI., once more confirmed all the Templars' privileges; while Philip, for his part, appointed Hugues de Peraud receiver of the royal revenues and, under pressure of the disastrous campaign in Flanders, in June granted a charter exempting the order from all hindrances to the acquisition of property. Two years later the king took refuge in the Temple from the violence of the Paris mob,[1] and so late as the spring of 1307 was present at the reception of a new Templar.[2]

Yet for some two years past the king had been plotting a treacherous attack on the order. His motives are clear: he had used every expedient to raise money, had robbed and expelled the Jews and the Lombard bankers, had debased the coinage; the suppression of the Templars would at once rescue him from their unwelcome tutelage and replenish his coffers. He cherished also another ambition. The question of an amalgamation of the great military orders had often been mooted; the project had been approved by successive popes in the interests of the Holy Land; it had been formally proposed at the Lyons council of 1274, only to be rejected by the opposition of the Templars and Hospitallers themselves. To Philip this scheme commended itself as an opportunity for bringing the orders under the control of the French crown; there was to be but one order, that of the "Knights of Jerusalem," of which the grand master was always to be a prince of the royal house of France.[3] Clearly, it only needed an excuse and a favourable opportunity to make him attack the Templars; and, once having attacked them, nothing short of their entire destruction would have been consistent with his safety. The excuse was found in the denunciation of the order for heresy and unspeakable immoralities by a venal informer; the opportunity was the election of a pope, Clement V., wholly devoted to the interests of the king of France.

Accusations.

For perhaps half a century there had been strange stories circulating as to the secret rites practised by the order at its midnight meetings, stories which probably had their origin in the extreme precautions taken by the Templars, originally perhaps for military reasons, to secure the secrecy of their proceedings, which excited popular curiosity and suspicion. Among the Templars alone of the religious orders the ceremonies of reception were conducted in strict privacy; chapters were held at daybreak with closely guarded doors, and no one participating was allowed to reveal what had passed, even to a fellow-member of the order, under pain of expulsion. It was inevitable that, considering the temper of the age, all this should lead to stories of rites too repulsive to bear the light. It was said that on his initiation each member had to disavow his belief in Christ, to spit upon the crucifix, to submit to indecent ceremonies. When the mass was celebrated the consecrating words *Hoc est corpus* were omitted; on Good Friday the holy cross was trampled under foot; and the Christian duty of almsgiving had ceased to be observed. Even the vaunted chastity of the order towards women had, it was said, been turned into the formal obligation to commit more horrible offences. These evil practices were part of the secret statute law of an order which in its nightly assemblies worshipped an idol named Baphomet[4] or the devil in the shape of a black cat. Devils, too, appeared in the form of beautiful women (*succubi*), with whom the brothers had carnal intercourse. In England the very children at their play bade one another beware of a Templar's kisses. Stranger stories yet were rife in England and gravely reported before bishops and priests—of children slain by their fathers because they chanced to witness the nightly orgies of the society; of one prior's being spirited away at every meeting of the general chapter; of the great preceptor's declaring that a single hair of a Saracen's beard was worth more than the whole body of a Christian man. In France they were said to roast their illegitimate children and smear their idols with the burning fat.

Denunciation of the order.

In the spring of 1304 or 1305 a certain Esquiu de Floyran of Beziers pretended to betray the "secret of the Templars" (*factum Templariorum*) to James II. of Aragon. The pious king, who had every reason to think well of the order, did not affect to be convinced; but the prospect of spoils was alluring, and he seems to have promised the informer a share of the booty if he could make good his charges.[5] Esquiu now turned to Philip of France, with more immediate success. For the purpose of collecting additional evidence the king caused twelve spies to find admission to the order, and in the meantime sought to win over the pope to his views. Bertrand de Got, archbishop of Bordeaux, who on the 5th of June 1305 became pope as Clement V., owed the tiara to the diplomacy of Philip's agents, perhaps to their gold; but though a weak man, and moreover a martyr to ill health, he was not so immediately accommodating as the king might have wished,

bound to respond to demands of the grand master for consignments of men and money, but their main duty was to assist the king in his wars against the Moors at home (*ad Sarracenorum Yspanie ofensionem*), a duty they fulfilled with conspicuous success and courage to the last. See Finke i. 3, *Papsttum und Untergang des Templerordens* (p. 27), "*Die Sonderstellung der aragonesischen* (*und spanischen*) *Templer*." See also Prutz, *Templerherrenorden*, p. 61 seq. In Portugal the Templars were practically feudatories of the crown, the master taking an oath of fealty to the king and his heir (*ib*. p. 59). (W. A. P.)

[1] For details see Lavocat, p. 120. [2] Finke i. 119.

[3] He himself was to be its first head, with the title of "King of Jerusalem." See the letter (No. 75) from Leget F. to Bernart F. in Finke ii. 114.

[4] Two of the Templars examined at Carcassonne spoke of an idol named Baphomet or a piece of wood on which was represented a figure of Baphomet. A Templar at Florence called the idol Mahomet or Magomet. Baphomet was a common mediæval corruption of Mahomet (Maphomet, Mahom, &c.), who was regarded, not as a false prophet only, but as a demon, a false god to whom human sacrifices were offered. Hence any unholy or fantastic rites came to be called *baffumerie*, *mahomerie*, *mômerie*, *i.e.* "mummery." Hammer-Purgstall's derivation from Βαφὴ Μητοῦς, *i.e.* the baptism of Metis (the supreme wisdom), has no trustworthy evidence to support it. See Loiseleur, *Doctrine secrète*, p. 97 seq.

[5] Finke ii. 83, No. 57, publishes a letter of Esquiu to the king, dated 21st January 1308, claiming his reward. Esquiu is the Squin de Florian of Villani; the other informer mentioned by him, Noffo Dei (Deghi) of Florence, had, however, nothing to do with the matter; he was in financial relations with the Temple at Paris, and was hanged for swindling. Nor was Esquiu's motive to save himself from execution, but purely mercenary. The existence of an informer, doubted by Lea (*Inquisition* iii. 255) and others, is now proved.

expressing his disbelief in the charges against the order, and, though promising an inquiry, doing his best to procrastinate. Philip determined to force his hand. All France was at this time under the jurisdiction of the Inquisition, and the Inquisition could act without consulting the pope. The grand inquisitor of France, William of Paris, was Philip's confessor and creature. The way was thus open for the king to carry out his plan by a perfectly legal method. His informers denounced the Templars to the Inquisition, and the grand inquisitor—as was the customary procedure in the case of persons accused of heresy—demanded their arrest by the civil power. On the 14th of September 1307, accordingly, Philip issued writs to his *baillis* and seneschals throughout the kingdom, directing them to make preparations to arrest the members of the order on the following 13th of October.

The Templars had for some time past been aware of the charges against them. On the 6th of June 1306 Pope Clement had summoned Jacques de Molay, the grand master, from Cyprus to France, in order to consult him on the projected crusade. He had obeyed the call, and, in an interview with the pope, had taken the opportunity to demand a full inquiry. They had, however, taken no measures to defend themselves; the sudden action of the king took them wholly by surprise; and on the night of Friday, the 13th of October 1307, their arrest was effected without difficulty, Jacques de Molay himself with sixty of his brethren being seized in Paris. Next day they were haled before the university of Paris, to hear the recital of their crimes; on Sunday the populace was collected in the royal gardens, where preachers inveighed against the iniquities of the order.

Arrest of the Templars.

The Templars were caught in toils from which there was no escape. To force them to confess, they were first tortured by the royal officials, before being handed over to the inquisitors to be, if need were, tortured again. In Paris alone thirty-six died under the process.[1] The result was, at the outset, all that the king could desire. Of 138 Templars examined in Paris between the 19th of October and the 24th of November, some of them old men who had been in the order the greater part of their lives, 123 confessed to spitting on (or "near") the crucifix at their reception. Many of the prisoners, on the other hand, confessed to all the charges, however grotesque. But the most damning confession was that of the grand master himself, publicly made with tears and protestations of contrition and embodied in a letter (October 25) sent to all the Templars in France. He had been guilty, he said, of denying Christ and spitting on the cross; the grosser charges he indignantly repudiated.[2]

To the pope, meanwhile, the proceedings in France were to the highest degree unwelcome. He had, indeed, become convinced, if not of the general guilt of the order, at least of the guilt of some of its members. But the affair was one which he desired to reserve for his own judgment; Philip's action he interpreted, rightly, as an encroachment of the civil power on the privileges and property of the Church, and his fears were increased when the French king, without consulting him, sent letters to King James of Aragon, Edward II. of England, the German king Albert and other princes, calling upon them to imitate his example. On the 27th of October Clement issued letters suspending the powers of the Inquisition in France. What followed is not clear, for the documentary evidence for these months is very defective. On the 17th of November James of Aragon wrote to Philip, in answer to his letter and the report of the proceedings in Paris forwarded to him,[3] expressing his surprise at the charges against the Templars, who had done himself and his forefathers great service against the infidel, but promising to proceed against them since required to do so 'by the Church."[4] In Portugal no action was taken at all. Edward II. of England replied that he must first receive information as to the charges from his officials in Agen (whence the charges had originated), and on the 5th of December he wrote to the kings of Aragon, Castile, Portugal and Sicily begging them not to believe the evil reports against the order (Prutz, p. 159). But meanwhile, on the 22nd of November, Pope Clement had issued a bull calling on all kings and princes to arrest the Templars everywhere, his motive probably being (according to Finke) to forestall the probable action of the secular powers and keep the affair in his own hands. All scruples and hesitations now vanished. In England the Templars were arrested on the 10th of January 1308, in Sicily on the 24th of the same month, in Cyprus on the 27th of May; in Aragon and Castile the process was less easy, for the knights, forewarned, had put their fortresses into a state of defence, notably their strong castle of Monzon, which was only taken after a long siege on the 17th of May, while the last of the Templars' strongholds, Castellat, did not fall until the 2nd of November.[5]

Meanwhile, on the 26th of May, Philip had made his solemn entry into Poitiers, where the pope and cardinals had already assembled for the purpose of conferring with the king on the matter. The debates that followed were protracted and stormy; but Philip was in a positon to back his argument for the suppression of the order by pressing other and more dangerous claims: the canonization of Celestine V., the condemnation of Boniface VIII. for heresy, the absolution of Guillaume de Nogaret, the executer of the outrage at Anagni, the summoning of a general council, the settlement of the papacy at Avignon. At last, on the 27th of June, an arrangement was come to. The king agreed to hand over to the papal commissioners the property[6] and persons of the Templars; Clement, for his part, withdrew the sentence of suspension against the grand inquisitor of France (July 5) and ordered an inquisition into the charges against individual Templars by the diocesan bishops with assessors nominated by himself. The examination of the grand master, of the grand visitor of France, and of the grand preceptors of Cyprus, Normandy and Aquitaine he reserved to himself. Inquisition was to be made into the conduct of the order in each country by special papal commissions; and the fate of the order as a whole was to be decided by a general council.[7]

These decisions were at once acted on. At Poitiers Clement had already heard the confessions of seventy-two Templars, carefully selected from the royal prisons (June 29 to July 1).[8] The grand master and the three preceptors were re-examined at Chinon, and renewed their old confessions (20th August). Lastly, the bull *Regnans in Coelo* summoned a great council at Vienne for the 1st of October 1311, when the question of the guilt of the order might be considered. Meanwhile the pope and cardinals had elaborated the organization of the new inquisition. In this the actual inquisitors, though admitted, played a quite subordinate part: the commissions centred round the diocesan bishops, who had as assessors prelates, abbots, priors and canonists. These commissions were twofold, usually—though erroneously—distinguished as papal and episcopal (both were in fact papal); the first were charged with the inquisition into the accusations against the order itself and the grand preceptors of the various countries, the second with

[1] Michelet, *Procès*, i. 36.

[2] Jacques de Molay's confession was partly due to fear of torture, partly to secure the withdrawal of a specific charge of unnatural crime brought against him by the Templar Guillaume de Giac (Gmelin ii., *Tab.* i. No. 12). But he continued to demand access to the pope, declaring that he could satisfactorily explain the practices of the order.

[3] Text in Finke ii. The writer, Romeus de Brugaria, of the university of Paris, boldly declares that the proceedings were taken *domini papae assensu precedente.*

[4] Text in Finke ii. 55.

[5] Finke i. 302 ff. Some of the Spanish Templars turned Mahommedan and joined the king of Granada in an invasion of Aragon (Finke ii. 188, No. 105).

[6] This was to be devoted to the cause of the Holy Land. In fact its administration fell into the hands of Philip's confidants and the greater part remained in his possession (Finke i. 227).

[7] For a detailed account of the negotiations see Finke i. 200 ff. He holds that Clement, though now convinced of the Templars' guilt, was anxious to treat them leniently and, if possible, to save the order (p. 215).

[8] See Gmelin ii., *Tab.* vii. and viii.

that into the accusations against individual Templars. The papal commission in Paris began its sessions on the 9th of August 1309; on the 12th, citations were issued to those Templars who "of their own free will" were prepared to come and defend the order. There was much confusion and delay, however, and the actual public trial did not begin till the 11th of April 1310.[1] Many Templars, trusting in the assurance implied in their citation, had volunteered to defend the order and withdrew their previous confessions. They were soon undeceived; the commission, presided over by the *garde des sceaux* of the king, the archbishop of Narbonne, was packed with creatures of the crown. The evidence given in Paris for or against the order was, it was soon found, used against the individual Templars on their return to the provinces; the retractation of a confession, under the rules set up for the diocesan inquisition, was punished with death by fire. On Tuesday the 12th of May, fifty-four Templars who had retracted their confessions before the commission were burnt in Paris by order of the archbishop of Sens;[2] a few days later four were burnt at Senlis, and towards the end of May nine more, by order of the archbishop of Reims. Forty-six Templars now withdrew their defence, and the commissioners in Paris decided (30th May) to adjourn till November. The second examination lasted from the 17th of December 1310 to the 16th of May 1311. Meanwhile (*c.* April 1311) Clement and Philip had come to terms. The pope condemned the Templars. The council of Vienne met in October 1311. A discussion arose as to whether the Templars should be heard in their own defence. Clement, it is said, broke up the session to avoid compliance; and when seven Templars offered themselves as deputies for the defence he had them cast into prison. Towards the beginning of March Philip came to Vienne, and he was seated at the pope's right hand when that pontiff delivered his sermon against the Templars (3rd April 1312), whose order had just been abolished, not at the general council, but in private consistory (22nd March). On 2nd May 1312 he published the bull *Ad Providam*, transferring the goods of the society, except for the kingdoms of Castile, Aragon, Portugal and Majorca, to the Knights of St John. The order was never formally pronounced guilty of the crimes laid to its charge; its abolition was distinctly, in the terms of Clement's bull *Considerantes Dudum*, "non per modum definitivae sententiae, cum eam super hoc secundum inquisitiones et processus super his habitos non possemus ferre de jure sed per viam provisionis et ordinationis apostolicae" (6th May 1312).

The trial.

The final act of the stupendous tragedy came early in 1314. Jacques de Molay, the grand master, had not hitherto risen to the height of his great position; the fear of torture alone had been enough to make him confess, and this confession had been used to extract avowals from his brethren, subject as they were to unspeakable sufferings and accustomed to yield to the military chief. Humiliation on humiliation had been heaped on the wretched man, public recantations, reiterated confessions. Before the papal commission he had flamed into anger, protested, equivocated—only in the end to repeat his confession once more. The same had happened before the commission of cardinals at Chinon; the audience with the pope, which he demanded, he had never obtained. On the 6th of May 1312 Pope Clement issued his final decision as to the fate of the Templars in general; that of the five great offices of the order he reserved in his own hand. With this a silence falls over the history of the Templars;[3] the fate of the order had been decided, that of the individuals still under trial was of little interest to contemporary chroniclers. Then the veil is suddenly lifted. Jacques de Molay has found his wonted courage at last, and with him Gaufrid de Charney, the preceptor of Normandy; on the 14th of March 1314 they were brought out on to a scaffold erected in front of Notre Dame, there in the presence of the papal legates and of the people to repeat their confessions and to receive their sentence of perpetual imprisonment. Instead, they seized the opportunity to withdraw their confessions and to protest to the assembled thousands the innocence of the order. King Philip the Fair did not wait to consult the Church as to what he should do; he had them burnt "in the little island" of the Seine "between the Augustinians and the royal garden"; with them perished Guy (the Guido Delphini of the trials), the youthful son of the dauphin of Auvergne. After the deaths of the pope and king, which followed shortly, the people remembered that the grand master had summoned them with his dying breath before the judgment seat of God; but the sole recorded contemporary protest is that of the Augustinians against the trespass committed by the royal officers on their land!

On the question of the guilt or innocence of the Templars in respect of the specific charges on which the order was condemned opinion has long been divided. Their innocence was maintained by the greatest of all their contemporaries, Dante,[4] and among others by the historian Villani and by the sainted Antoninus, archbishop of Padua. In more recent times a certain heat was introduced into the discussion of the question owing to its having been for centuries brought into the arena of party controversy, between Protestants and Catholics, Gallicans and Ultramontanes, Freemasons and the Church. Thus in 1654 Pierre Du Puy, librarian of the Bibliothèque Royale, published his work on the Templars to confute those who sought to establish their innocence in order to discredit a king of France. On the other hand, Nicolas Gurtler published his *Historia Templariorum* (Amsterdam, 1691, 2nd ed. 1703) to show, as a good Protestant, that the Templars had the usual vices of Roman Catholics, while, according to Loiseleur, the later editors of Du Puy (especially of the 1751 edition,[5] ostensibly printed at Brussels) were Freemasons who, under false names, garbled the old material and inserted new in the interests of the supposed origin of their own order in that of the Templars.[6] Several Roman Catholic champions of the order now entered the field, *e.g.* the Benedictine historian of Languedoc, Dom Dominique Joseph Vaissète, and notably the Premonstratensian canon R. P. M. Jeune, prior of Etival, who in 1789 published at Paris his *Histoire critique et apologétique de l'ordre des chevaliers . . . dits Templiers*, a valuable work directed specifically against Gurtler and Du Puy. In the 19th century a fresh impetus was given to the discussion by the publication in 1813 of Raynouard's brilliant defence of the

[1] This was, of course, only one of some twenty-five separate commissions in different countries. It was, however, the most important and is the best known.

[2] Philippe de Marigny, brother of Enguerrand de Marigny, the king's minister, had been appointed archbishop of Sens at Philip IV.'s instance in April, and was naturally full of zeal for the royal cause. The condemned Templars appealed to the papal commission, which was sympathetic, but replied that it had no authority to interfere with the archbishop's ordinary jurisdiction. (Raynouard, p. 92.)

[3] Finke devotes an interesting chapter to tracing what became of the property of the order and of the individual Templars. The property was nominally handed over to the Hospitallers, but most of it actually remained in the hands of the sovereigns or their followers (Philip, *e.g.*, claimed a vast sum for the expenses incurred in suppressing the order and torturing its members). In the Spanish peninsula the Temple castles and estates were in some cases handed over to other military orders; in Portugal to the new order of Christ, 1319; in Castile to those of Ucles and Calatrava; in Aragon one frontier castle with its domain, Montasia, was given to the knights of Calatrava; the rest—so far as they had not been annexed by the king and the *ricos hombres*—to the Hospitallers. As to the Templars: they were granted in most cases generous pensions; some continued to live in groups, though without organization, on their old property; others joined various orders; many married, on the plea that the suppression of the order had released them from their vows; while others, again, took service with the Moors in Africa. (Finke, i. cap. x.)

[4] Veggio il nuovo, Pilato si crudele,
Che ciò nol sazia, ma, senza decreto,
Porta nel tempio le cupide vele.—(*Purg.* xx. 92.)

[5] *Histoire de l'ordre militaire des templiers, &c.* The titles of the various editions differ.

[6] There is, of course, no foundation whatever for this claim. It is examined and refuted, *inter alios*, by Wilcke, iii. 383 seq. A delightfully absurd attempt to assert the continuity of the modern Order of Knights Templars, which still has a considerable organization in the United States, with the suppressed order, is made by Jeremy L. Cross in *The Templars' Chart* (New York, 1845); he actually gives a complete list of grand masters from Hugues de Payns to Sir Sidney Smith (1838), and asserts that "the Encampment of Baldwin which was established at Bristol by the Templars who returned with Richard I. from Palestine, still continues to hold its regular meetings, and is believed to have preserved the ancient costume and ceremonies of the order."

order.[1] The challenge was taken up, among others, by the famous orientalist Friedrich von Hammer-Purgstall, who in 1818 published his *Mysterium Baphometis revelatum*,[2] an attempt to prove that the Templars followed the doctrines and rites of the Gnostic Ophites, the argument being fortified with reproductions of obscene representations of supposed Gnostic ceremonies and of mystic symbols said to have been found in the Templars' buildings. Wilcke, while rejecting Hammer's main conclusions as unproved, argued in favour of the existence of a secret doctrine based, not on Gnosticism, but on the unitarianism of Islam, of which Baphomet (Mahomet) was the symbol.[3] On the other hand, Wilhelm Havemann (*Geschichte des Ausganges des Tempelherrenordens*, Stuttgart and Tübingen, 1846) decided in favour of the innocence of the order. This view was also taken by a succession of German scholars, in England by C. G. Addison, and in France by a whole series of conspicuous writers: *e.g.* Mignet, Guizot, Renan, Lavocat. Others, like Boutaric,[4] while rejecting the charge of heresy, accepted the evidence for the *spuitio* and the indecent kisses, explaining the former as a formula of forgotten meaning and the latter as a sign of *fraternité!* Michelet, who in his history of France had expressed himself favourably to the order, announced his conversion to the opposite opinion in the prefaces to his edition of the *Procès*. This view was reinforced by the work in which Loiseleur endeavoured to prove that the order had secretly rejected Christianity in favour of an heretical religion based on Gnostic dualism as taught by the Cathari;[5] it was crowned with the high authority of Ranke in the great *Weltgeschichte* (8 Theil, 1887, p. 621 ff.); it has been adopted in the later *Weltgeschichte* of Weber (8 Theil, 1887, p. 521 ff.). The greatest impulse to this view was, however, given by the brilliant contributions of Hans Prutz. The first of these, the *Geheimlehre*, in the main an expansion of Loiseleur's argument, at once raised up a host of critics; and, as a result of five years' study of the archives at Rome and elsewhere, Konrad Schottmüller published in 1887 his *Untergang des Templerordens*, in which he claimed to have crushed Prutz's conclusions under the weight of a mass of new evidence. The work was, however, uncritical and full of conspicuous errors, and Prutz had little difficulty in turning many of its author's arguments against himself. This was done in the *Entwicklung und Untergang des Tempelherrenordens* (1888), in which, however, Prutz modifies his earlier views so far as to withdraw his contention that the Templars had a "formally developed secret doctrine," while maintaining that the custom of denying Christ and spitting on the cross was often, and in some provinces universally, practised at the reception of the brethren, "as a coarse test of obedience, of which the original sense had partly been forgotten, partly heretically interpreted under the influence of later heresies."[6] This view was maintained by Mr T. A. Archer in the 9th ed. of the *Encyclopaedia Britannica*. It was criticized and rejected by Döllinger in the last of his university lectures (19th Nov. 1889), and by Karl Wenck in several articles in the *Göttinger Gelehrte Anzeigen;* and it was further attacked by J. Gmelin (*Schuld oder Unschuld*, 2 Bd. 1893), whose work, in spite of its somewhat ponderous polemic, is valuable as a mine of learning and by reason of the sources (notably the tables of the evidence taken at the trials) which it publishes. H. C. Lea, in his *History of the Inquisition* (1888, vol. iii.), had already come independently to the conclusion that the Templars were innocent. Lastly appeared the fascinatingly interesting and closely reasoned book of Professor H. Finke (1907) which, based partly on a mass of new material drawn from the Aragonese archives, had for its object to supplement the work of Gmelin and to establish the innocence of the order on an incontrovertible basis.

[1] F. J. M. Raynouard, *Monuments historiques, relatifs à la condamnation des chevaliers du Temple*, &c. (Paris, 1813).

[2] In vol. vi. of *Fundgruben des Orients* (Vienna, 1818). In reply to his critics Hammer published in 1855 his "Die Schuld der Templer" (*K. Akad. zu Wien Denkschrift.*, vi.), in which he reproduced drawings of two remarkable caskets, sculptured with Gnostic pictures, from the former collection of the duc de Blacas, said to have been found on the sites of Temples. To the present writer the evidence that any of these objects had been connected with the Templars seemed singularly unconvincing even before he had seen the trenchant criticisms of Wilcke (ii. 290, ed. 1862, Beilage 22) and Loiseleur (*Doctrine secrète*, 4me partie, p. 97 seq.). If such objects existed, why were none brought up as evidence against the Templars at their trial?

[5] J. Loiseleur, *La Doctrine secrète des Templiers* (Orleans, 1872).

[6] Prutz points out, with much truth, that the failure of the Crusades had weakened men's absolute belief in Christianity, at least as represented by the medieval Church (*Kulturgeschichte der Kreuzzüge*, p. 268 ff.). Walther von der Vogelweide had merely accused the archangels of neglecting their duty (Pfeiffer's ed. 1880, p. 288); a Templar minstrel complained that God Himself had fallen asleep! (Prutz, *Tempelherrenorden*, 126.)

In the opinion of the present writer, the defenders of the order have proved their case. Even the late Mr Archer, who took the contrary view, was inclined to restrict it to the Templars in France. "The opinion that the monstrous charges brought against the Templars were false," he wrote (*Ency. Brit.*, 9th ed. xiii. 164), "and that the confessions were only extracted by torture is supported by the general results of the investigation (in almost every country outside France), as we have them collected in Raynouard, Labbe, and Du Puy. In Castile, where the king flung them into prison, they were acquitted at the council at Salamanca. In Aragon, where they held out for a time in their fortresses against the royal power, the council of Tarragona proclaimed in their favour (4th November 1312). In Portugal the commissioners reported that there were no grounds for accusation. At Mainz the council pronounced the order blameless. At Treves, at Messina, and at Bologna, in Romagna and in Cyprus, they were either acquitted or no evidence was forthcoming against them. At the council of Ravenna the question as to whether torture should be used was answered in the negative except by two Dominicans; all the Templars were absolved—even those who had confessed through fear of torture being pronounced innocent (18th June 1310). Six Templars were examined at Florence, and their evidence is for its length the most remarkable of all that is still extant. Roughly speaking, they confess with the most elaborate detail to every charge,—even the most loathsome; and the perusal of their evidence induces a constant suspicion that their answers were practically dictated to them in the process of the examination or invented by the witnesses themselves.[7] In England, where perhaps torture was not used, out of eighty Templars examined only four confessed to the charge of denying Christ, and of these four two were apostate knights. But some English Templars would only guarantee the purity of their own country. That in England as elsewhere the charges were held to be not absolutely proved seems evident from the form of confession to be used before absolution, in which the Templars acknowledge themselves to be defamed in the matter of certain articles that they cannot purge themselves. In England nearly all the worst evidence comes at second or third hand or through the depositions of Franciscans and Dominicans," *i.e.* the rivals and enemies of the order. But what is the nature of the evidence "too strong to be explained away" on which Mr Archer bases his opinion that certain of the charges were proved "at least in France"? The modern practice of the English courts tends to discount altogether the value as evidence of confessions, even freely made. What is the value of these confessions of the Templars which lie before us in the Tables published by Gmelin? The procedure of the Inquisition left no alternative to those accused on "vehement suspicion" of heresy, but confession or death under lingering torture; to withdraw a confession meant instant death by fire. The Templars, for the most part simple and illiterate men, were suddenly arrested, cast separately into dark dungeons, loaded with chains, starved, terrorized, and tortured. They were told the charges to which their leaders had confessed, or were said to have confessed: to repeat the monotonous formula admitting the *spuitio super crucem* and the like was to obtain their freedom at the cost of a comparatively mild penance. The wonder is not that so many confessed, but that so many persisted in their denial. The evidence, in short, is, from the modern point of view, wholly worthless, as even some contemporaries suspected it to be.

A word must be added as to the significance of the work of the Templars and of the manner of their fall in the history of the world. Two great things the order had done for European civilization: in the East and in Spain it had successfully checked the advance of Islam; it had deepened and given a religious sanction to the idea of the chivalrous man, the *homo legalis*, and so opened up, to a class of people who for centuries to come were to exercise enormous influence, spheres of activity the beneficent effects of which are still recognizable in the world.[8] On the other hand, the destruction of the Templars had three consequences fateful for Christian civilization: (1) It facilitated the conquests of the Turks by preventing the Templars from playing in Cyprus the part which the Knights of St John played in Malta.[9] (2) It partly set a precedent for, partly confirmed, the cruel criminal procedure of France, which lasted to the Revolution. (3) It set the seal of the highest authority on the

[7] See the evidence in full, ap. Loiseleur, pp. 172–212.

[8] G. Schnürer, quoted in Finke, i. 1.

[9] In his essay on the Templars (*The Spanish Story of the Armada and other Essays*, 1892) Froude says that the order lacked "the only support that never fails—some legitimate place among the useful agencies of the time." Was there no use for them against the advancing tide of Turkish conquest in the East? Or in Spain against the Moorish powers? If not, why did the Hospitallers survive? Froude's contribution is but a popular lecture, however, and, for all its beauty of style, characteristically careless (*e.g.* such mistakes as Hugh *von* Peyraud, Esquin *von* Florian).

popular belief in witchcraft and personal intercourse with the devil, sanctioned the expedient of wringing confessions of such intercourse from the accused by unspeakable tortures, and so made possible the hideous witch-persecutions which darkened the later middle ages and, even in Protestant countries, long survived the Reformation. "If I were to name a day in the whole history of the world," said Döllinger at the conclusion of his last public lecture, "which appears to me in the truest sense as a *dies nefastus*, I should be able to name no other than the 13th of October 1307."[1]

AUTHORITIES.—A great mass of original sources has now been published. Those given by Du Puy, though often valuable, were selected and edited with a purpose, as Jeune pointed out. A new departure was made with the publication of Michelet's *Procès des Templiers* (t. i. 1851, t. ii. 1861), an edition of the original minutes of the trial preserved at the Bibliothèque Nationale (it is specially interesting as the earliest complete and detailed record of a criminal trial in existence). This is elaborately analysed and the results tabulated in vol. ii. of Gmelin. Of documents published in other works the most important collections are those in Schottmüller (mainly from the Vatican Archives) and Finke (Aragonese Archives). The Rule of the Temple has been several times published; the most accessible edition, giving the various Rules with critical commentary, is that of H. de Curzon, *La Règle du Temple* (Paris, 1886); see also Maillard de Chambure, *Règle et statuts secrets des Templiers, préc. de l'hist. de cette ordre* (Dijon—Paris, 1840).

A comprehensive bibliography of works is given by Ulysse Chevalier in his *Répertoire des sources hist. Topo-biblio-graphie*, s.v. "Templiers." Of the works not fully indicated in the text must be mentioned M. Lavocat, *Procès des frères et de l'ordre du Temple* (Paris, 1888); G. Schnürer, *Die ursprüngliche Templerregel* (1903); H. Finke, *Papsttum und Untergang des Templerordens* (Münster,-i.-W., 1907); C. G. Addison, *The Knights Templars* (London, 3rd ed. 1854), which contains a valuable account of the suppression of the order in England. For the order and its suppression in Ireland see Herbert Wood, "The Templars in Ireland," in *Proceedings of the Royal Irish Academy*, vol. xxvi. Section c. p. 327 (Dublin, 1906–1907). (W. A. P.)

TEMPLE, FREDERICK (1821–1902), English divine, archbishop of Canterbury, was born in Santa Maura, one of the Ionian Islands, being the son of Major Octavius Temple, who was subsequently appointed lieutenant-governor of Sierra Leone. On his retirement he settled in Devonshire as a small landowner, and contemplated a farming life for his son Frederick, giving him a practical training to that end. But the boy was sent to Blundell's School, Tiverton, and soon exhibited abilities which marked him out for a different career. He retained through life a warm affection for the school, where he did well both in the classes and the games, and was famous as a walker. His father's means were narrow, and the boy knew that he must win his own way in life. He took the first important step in that way by winning a scholarship at Balliol College, Oxford, before he was quite seventeen years old. The "Tractarian Movement" had set in five years earlier, but the memorable tract, No. 90, had not yet been written, and Temple entered a university which was vibrating with intellectual and religious excitement. After much discussion and reflection he drew closer to the camp of "the Oxford Liberal Movement." In 1842 he took a "double-first" and was elected fellow of Balliol, and lecturer in mathematics and logic. Four years later he took orders, and with the aim of helping forward the education of the very poor, he accepted the headship of Kneller Hall, a college which the government formed for the training of masters of workhouse and penal schools. But the experiment was not altogether successful, and Temple himself advised its abandonment in 1855. He then accepted a school-inspectorship, which he held until he went to Rugby in 1858. In the meantime he had attracted the admiration of the prince consort, and in 1856 he was appointed chaplain-in-ordinary to the queen. In 1857 he was select preacher at his university.

At Rugby Dr Arnold had died in 1842 and had been succeeded by Dr Tait, who again was followed by Dr Goulburn. Upon the resignation of the latter the trustees appointed Temple, who in that year (1858) had taken the degrees of B.D. and D.D. His life at Rugby was marked by great energy and bold initiative. Whilst making the school a strong one on the classical side, he instituted scholarships in natural science, built a laboratory, and gave importance to that side of the school work. He had the courage also to reform the games, in spite of all the traditions of the playing fields. His own tremendous powers of work and his rugged manner somewhat alarmed his boys at first, but his popularity was soon undisputed, and he brought up the school to a very high level. His school sermons were deeply impressive: they rooted religion in the loyalties of the heart and the conscience, and taught that faith might dwell secure amid all the bewilderments of the intellect, if only the life remained rooted in pure affections and a loyalty to the sense of duty. It was two years after he had taken up his work at Rugby that the volume entitled *Essays and Reviews* gave rise to an extraordinary storm. The first essay in the book, "The Education of the World," was by Dr Temple. It was declared in a prefatory note to the volume that the authors were responsible only for their respective articles, but some of these were deemed so destructive that many people banned the whole book, and a noisy demand, led by Samuel Wilberforce, then bishop of Oxford, called on the headmaster of Rugby to dissociate himself from his comrades. Temple's essay had treated of the intellectual and spiritual growth of the race, and had pointed out the contributions made respectively by the Hebrews, the Egyptians, the Greeks, the Romans, and others. It was generally declared by the critics of the volume to be in itself harmless, but was blamed as being found in bad company. Temple refused, so long as the storm lasted, to comply with the request that he would repudiate his associates, and it was only at a much later date (1870) that he saw fit quietly to withdraw his essay. In the meantime, however, he printed a volume of his Rugby sermons, to show definitely what his own religious positions were.

In politics Temple was a follower of Mr Gladstone, and he approved of the disestablishment of the Irish Church. He also wrote and spoke in favour of Mr Forster's Education Act, and was an active member of the Endowed Schools Commission. In 1869 Mr Gladstone offered him the deanery of Durham, but this he declined on the ground of his strong interest in Rugby. When later in the same year, however, Henry Phillpotts, bishop of Exeter, died, the prime minister turned again to Temple, and he accepted the bishopric of that city so dear to him from boyhood, and left Rugby for a home amongst his own people. The appointment, however, raised a fresh storm.

G. A. Denison, archdeacon of Taunton, Lord Shaftesbury, and others formed a strong committee of protest, whilst Pusey declared that "the choice was the most frightful enormity ever perpetrated by a prime minister." At the confirmation of his election counsel was instructed to object to it, and in the voting the chapter was divided. But Gladstone stood firm, and Temple was duly consecrated on the 21st of December 1869. There were at first murmurings among his clergy against what they deemed his harsh control, but his real kindness soon made itself felt, and, during the sixteen years of his tenure of the see, his sound and vigorous rule dissipated the prejudices against him, so that when, on the death of Dr John Jackson in 1885, he was translated to London, the appointment gave general satisfaction. In 1884 he was Bampton Lecturer, taking for his subject "The Relations between Religion and Science." In 1885 he was elected honorary fellow of Exeter College, Oxford.

Dr Temple's tenancy of the bishopric of London was marked, if possible, by more strenuous labours than ever. His normal working day at this time was one of fourteen or fifteen hours, and he refused to spare himself one hour of toil, though under the strain blindness was rapidly coming on. He was still felt by many of his clergy and by candidates for ordination to be a rather terrifying person, and to enforce almost impossible standards of diligence, accuracy and preaching efficiency, but his manifest devotion to his work and his zeal for the good of the people rooted him deeply in the general confidence. In London he was not less conspicuous as a temperance worker than he had been in Exeter, and the artisan classes instinctively

[1] Döllinger, *Akademische Vorträge* (Munich, 1891), ix. "*Der Untergang des Templerordens.*"

recognized him as their friend. When, in view of his growing blindness, he offered to resign the bishopric, he was induced to reconsider his proposal, and on the sudden death of Archbishop Benson in 1896, though now seventy-six years of age, he accepted the see of Canterbury.

As archbishop he presided in 1897 over the decennial Lambeth Conference. In the same year Dr Temple and his brother archbishop issued an able reply to an encyclical of the pope which denied the validity of Anglican orders. In 1900 the archbishops again acted together, when an appeal was addressed to them by the united episcopate, to decide the vexed questions of the use of incense in divine service and of the reservation of the elements. After full hearing of arguments they gave their decision against both the practices in question. During his archbishopric Dr Temple was deeply distressed by the divisions which were weakening the Anglican Church, and many of his most memorable sermons were calls for unity. His first charge as primate on "Disputes in the Church" was felt to be a most powerful plea for a more catholic and a more charitable temper, and again and again during the closing years of his life he came back to this same theme. He was zealous also in the cause of foreign missions, and in a sermon preached at the opening of the new century he urged that a supreme obligation rested upon Britain at this epoch in the world's history to seek to evangelize all nations. In 1900 he presided over the World Temperance Congress in London, and on one occasion preached in the interests of women's education. In 1902 he discharged the important duties of his office at the coronation of King Edward VII., but the strain at his advanced age told upon his health. During a speech which he delivered in the House of Lords on the 2nd of December 1902 on the Education Bill of that year, he was seized with sudden illness, and, though he revived sufficiently to finish his speech, he never fully recovered, and died on the 23rd of December 1902. He was interred in Canterbury cathedral four days later. His second son, William Temple (b. 1881), who had a distinguished career at Oxford, was in 1910 appointed headmaster of Repton.

See Archdeacon E. G. Sandford, *Frederick Temple: an Appreciation* (1907), with biographical introduction by William Temple; *Memoirs of Archbishop Temple*, by "Seven Friends," ed. E. G. Sandford (1906).

TEMPLE, SIR RICHARD, Bart. (1826–1902), English administrator, a descendant in the female line of the Temples of Stowe, was born on the 8th of March 1826, and after being educated at Rugby and Haileybury, joined the Bengal Civil Service. His industry and ready pen soon obtained appreciation, and after acting as private secretary for some years to John Lawrence in the Punjab, and gaining useful financial experience under James Wilson, he was appointed Resident at Haidarabad. In 1867 he was made K.C.S.I. In 1868 he became a member of the supreme government, first as foreign secretary and then as finance minister; and he did admirable work during the famine of 1874, in the course of which he was made lieutenant-governor of Bengal. His services were recognized by the bestowal of a baronetcy in 1876. In 1877 he was made governor of Bombay, and his activity during the Afghan War of 1878–80 was untiring. In 1880 he left India to enter on a political career in England, but it was not till 1885 that he was returned as a conservative for the Evesham division of Worcestershire. Meanwhile he produced several books on Indian subjects. In parliament he was assiduous in his attendance, and he spoke on Indian subjects with admitted authority; but he was not otherwise a parliamentary success, and to the public he was best known by the caricatures in *Punch*, which exaggerated his physical peculiarities and made him look like a lean and hungry tiger. In 1885 he became vice-chairman of the London School Board, and as chairman of its finance committee he did useful and congenial work. In 1892 he changed his constituency for the Kingston division, but in 1895 he retired from parliament, being in 1896 made a Privy Councillor. He had kept a careful journal of his parliamentary experiences, intended for posthumous publication; and he himself published a short volume of reminiscences. He died at Hampstead on the 15th of March 1902. He was twice married, and left a daughter and three sons, all of the latter distinguishing themselves in the public service.

TEMPLE, RICHARD GRENVILLE-TEMPLE, 1st Earl (1711–1779), English statesman, eldest son of Richard Grenville (d. 1727) of Wootton, Buckinghamshire, was born on the 26th of September 1711. His mother was Hester (*c.* 1690–1752), daughter, and ultimately heiress, of Sir Richard Temple, Bart. (1634–1697), of Stowe, Buckinghamshire,[1] and sister of Richard Temple, Viscount Cobham, whose title she inherited under a special remainder in 1749; in the same year, her husband having been long dead, she was created Countess Temple. Her son, Richard Grenville, was educated at Eton, and in 1734 was returned to parliament as member for the borough of Buckingham. In 1752, on the death of his mother, he inherited her titles together with the rich estates of Stowe and Wootton; and he then took the name of Temple in addition to his own surname of Grenville. The turning point in his political fortunes was the marriage of his sister Hester in 1754 to William Pitt, afterwards earl of Chatham. Although Lord Temple was a man of little ability and indifferent character, Pitt persistently linked his own career with that of his brother-in-law. In November 1756 Temple became first lord of the admiralty in the ministry of Devonshire and Pitt. He was intensely disliked by George II., who dismissed both him and Pitt from office in April 1757. But when the memorable coalition cabinet of Newcastle and Pitt was formed in June of the same year, Temple received the office of privy seal. He alone in the cabinet supported Pitt's proposal to declare war with Spain in 1761, and they resigned together on the 5th of October. From this time Temple became one of the most violent and factious of politicians, and it is difficult to account for the influence, wholly evil, which he exerted over his illustrious brother-in-law. He himself is said to have avowed that "he loved faction, and had a great deal of money to spare." He was at variance with his younger brother, George Grenville, when the latter became first lord of the treasury in April 1763, and he had no place in that ministry; but the brothers were reconciled before 1765, when Temple, who probably aimed at forming a ministry mainly confined to his own family connexions, refused to join the government, and persuaded Pitt to refuse likewise. A few weeks later the king offered the most liberal terms to induce Pitt to form or join an administration; and "a ministry directed by that great statesman," says Lecky, "would have been beyond all comparison the most advantageous to the country; it had no serious difficulty to encounter, and Pitt himself was now ready to undertake the task, but the evil genius of Lord Temple again prevailed. Without his co-operation Pitt could not, or would not proceed, and Temple absolutely refused to take office even in the foremost place." Pitt's continued refusal to join the first Rockingham administration was no doubt partly due to the same disastrous influence, though before the close of 1765 the old friendship between the brothers-in-law was dissolving; and when at last in July 1766 Pitt consented to form a government, Temple refused to join; being bitterly offended because, although offered the head of the treasury, he was not to be allowed an equal share with Pitt in nominating to other offices. Temple forthwith began to inspire the most virulent libels against Pitt; and in conjunction with his brother George he concentrated the whole Grenville connexion in hostility to the government. After George Grenville's death in 1770 Lord Temple retired almost completely from public life. He died on the 12th of September 1779.

[1] The Temple family belonged originally to Leicestershire, where, at Temple Hall, the elder line had resided since the 14th century. Peter Temple (1600–1663), the regicide, was a member of this elder line; a younger branch had settled in Oxfordshire and passed thence to Buckinghamshire, where John Temple purchased Stowe in 1589. This John was brother of Anthony, who was great-grandfather of Sir William Temple, the famous statesman. John Temple's son Thomas, who was created a baronet in 1611, was the great-grandfather of Earl Temple.

Lord Temple was entirely without statesmanship; he possessed an insatiable appetite for intrigue, and is said to have been the author of several anonymous libels, and the inspirer of many more. Macaulay's well-known comparison of him with a mole working below "in some foul, crooked labyrinth whenever a heap of dirt was flung up," which perpetuates the spleen of Horace Walpole, perhaps exceeds the justice of the case; but there can be no question that Temple's character as a public man was rated very low by his contemporaries. In private life he used his great wealth with generosity to his relations, friends and dependents. Pitt was under pecuniary obligation to him. He paid the costs incurred by Wilkes in litigation, and he provided the agitator with the freehold qualification which enabled him to stand for Middlesex in the famous election of 1768.

In addition to the estates he inherited, Temple gained a considerable fortune by his marriage in 1737 with Anne, daughter and co-heiress of Thomas Chambers of Hanworth, Middlesex; a volume of poems by her was printed at the Strawberry Hill press in 1764. The only issue of the marriage being a daughter who died in infancy, Temple was succeeded in the earldom by his nephew George (1753–1813), second son of George Grenville the prime minister, who then assumed in addition to the name of Grenville not only the name of Temple, but also that of Nugent, his wife being daughter and co-heiress of Robert, Viscount Clare, afterwards Earl Nugent. The 2nd Earl Temple was lord-lieutenant of Ireland in 1782–3; in 1784 was created marquess of Buckingham; and was again lord-lieutenant of Ireland in 1787–9.

His son and successor, Richard Temple-Nugent-Brydges-Chandos-Grenville (1776–1839), was created duke of Buckingham and Chandos in 1822, his wife being only daughter of the 3rd duke of Chandos; he was in the same patent created Earl Temple of Stowe, with special remainder as regards this title, in virtue of which, on the death without male issue in 1889 of the 3rd duke of Buckingham and Chandos and the consequent extinction of the original earldom of Temple, the title of Earl Temple of Stowe devolved upon William Stephen Gore-Langton (1847–1902), whose mother was granddaughter of the 1st duke of Buckingham, grantee of this earldom. In 1902 Algernon William Stephen Temple-Gore-Langton (b. 1871) became 5th Earl Temple.

See *The Grenville Papers* (London, 1852), a considerable portion of which consists of Earl Temple's correspondence; Horace Walpole, *Memoirs of the Reign of George II.*, 3 vols. (London, 1847); *Memoirs of the Reign of George III.*, 4 vols. (London, 1845 and 1894); Earl Waldegrave, *Memoirs 1754–8* (London, 1821); Sir N. W. Wraxall, *Historical Memoirs*, edited by H. B. Wheatley, 5 vols. (London, 1884); *Correspondence of Chatham*, edited by W. S. Taylor and J. H. Pringle, 4 vols. (London, 1838–40); W. E. H. Lecky, *History of England in the Eighteenth Century*, vols. ii. and iii. (7 vols., London, 1892). (R. J. M.)

TEMPLE, SIR WILLIAM, Bart. (1628–1699), English statesman, diplomatist, and author, was born in London, and came of an old English family, but of the younger branch of it, which had for some time been settled in Ireland. He was the eldest son of Sir John Temple (1600–1677), Irish master of the rolls, whose father was Sir William Temple (1555–1627), provost of Trinity College, Dublin. His mother was Mary Hammond. Temple received a liberal education, calculated to produce that moderation of judgment for which he was afterwards remarkable. He was first a pupil of his uncle Dr Henry Hammond, the divine, after which he went to the grammar-school at Bishop Stortford, and then to the Puritan college of Emmanuel at Cambridge, where he came under the influence of Cudworth. At the commencement of the civil troubles his father embraced the popular cause and was deprived of his office. Coming to England, he sat in the Long Parliament as member for Chichester, and was one of the recalcitrant members turned out by Colonel Pride. Before this event happened his son had left Cambridge, without taking a degree, and in 1647 started to travel abroad. In the Isle of Wight, while on his way to France, he fell in with Dorothy Osborne, and won her affections. Her father, Sir Peter Osborne, was governor of Guernsey and a Royalist. Her family were opposed to the match, and threw difficulties in the way, which hindered its consummation for seven years. During this period Temple travelled in France, Spain, Holland, and other countries, gaining knowledge of the world and keeping up a constant correspondence with his betrothed. At length, apparently in 1654, the difficulties were surmounted and the marriage took place. In 1655 Temple and his wife went to Ireland. The next five years were spent in the house of Sir John Temple, who had made his peace with Cromwell, and had resumed his official position. His son took no part in politics, but lived the life of a student and a country gentleman.

The accession of Charles II. rescued Temple, like many others, from obscurity. In 1660 he sat in the convention parliament at Dublin as member for Carlow, and he represented the same county along with his father in the regular parliament that followed. After a short visit to England in 1661, as commissioner from the Irish parliament, he finally removed thither in 1663. There he attached himself to Arlington, secretary of state, and two years later received his first employment abroad. It was in March 1665 that the disastrous war with the United Netherlands began. Charles II. was anxious to obtain allies, especially as Louis XIV. was taking up a hostile attitude. At this juncture Christoph Bernhard van Galen, bishop of Münster, sent an envoy to England, offering to attack the Dutch if the English government would supply the means. Temple was sent over to negotiate a treaty, and in this business gave evidence not only of the diplomatic skill but of the peculiar candour and frankness for which he was afterwards so distinguished. He was successful in making the treaty, but it was rendered ineffectual by the declaration of war by France, the threats of Louis, and the double-dealing of the prelate, who, after receiving a great part of the subsidy, made a separate peace with the Netherlands. As a reward for his services Temple was created a baronet, and in October 1665 became the English representative at the viceregal court at Brussels. While the war continued, Temple's duties consisted chiefly in cultivating good relations with Spain, which was a neutral in the quarrel between England and the Dutch, but was threatened by the claims of Louis XIV. on the Spanish Netherlands. Louis's designs became apparent in the spring of 1667, when he marched an army into Flanders. This event was one of those which led to the peace of Breda, and to the subsequent negotiations, which are Temple's chief title to fame. The French conquests were made at the expense of Spain, but were almost equally dangerous to the United Netherlands, whose independence would have been forfeited had Louis succeeded in annexing Flanders. While the French were taking town after town, Temple made a journey into Holland and visited De Witt. The friendship established and the community of views discovered during this interview facilitated the subsequent negotiations. Temple had for some time pressed on his government the necessity of stopping the French advance, and had pointed out the way to do so, but it was not till December 1667 that he received instructions to act as he had suggested. He at once set out for The Hague, and in January 1668 a treaty was made between England and the United Netherlands, which, being joined shortly afterwards by Sweden, became known as the Triple Alliance. It was a defensive treaty, made against the encroachments of France. Whether we regard the skill and celerity with which the negotiations were conducted or the results of the treaty, the transaction reflects great credit on Temple. The French king was checked in mid-career, and, without a blow being struck, was obliged to surrender almost all his conquests. Pepys records public opinion on the treaty by saying that it was "the only good public thing that hath been done since the king came into England."

Unfortunately the policy thus indicated was but short-lived. In taking up a hostile attitude towards France Charles's object had apparently been only to raise his price. Louis took the hint, increased his offers, and two years later the secret treaty of Dover reversed the policy of the Triple Alliance. Meanwhile Temple had developed the good understanding with the Dutch by contracting a commercial treaty with them (February 1668), and had acted as English plenipotentiary at Aix-la-Chapelle, where peace between France and Spain was made in May 1668. Shortly afterwards he was appointed ambassador at The Hague. Here he lived for two years on good terms both with De Witt and with the young prince of Orange, afterwards William III. The treaty of Dover led to Temple's recall; but the plot was not yet ripe, and Temple nominally held his post for another year. He perceived, however, that his day was over and retired to his house at Sheen. In June 1671 he received his formal dismissal. The war with the Netherlands broke out next year, and was almost as discreditable to England as that of 1665. Want of success and the growing strength of the opposition in parliament forced Charles to make peace, and Temple was brought out of his retirement to carry through the change of front. After a negotiation of three days, carried on through the medium of the Spanish ambassador, the treaty of Westminster was made (February 1674). As a recognition of his services Temple was now offered the embassy to Spain. This he declined, as well as the offer of a far more important post, that of secretary of state, but accepted instead a renewal of his embassy to The Hague, whither he went in July 1674. In the March following he was nominated ambassador to the congress at Nijmwegen; but, owing to the tortuousness of Charles's dealings, it was not till July 1676 that he entered that town. The negotiations dragged on for two years longer, for Charles was still receiving money from France, and English mediation was no more than a ruse. In the summer of 1677 Temple was summoned to England and received a second offer of the secretaryship of state, which he again declined. In the autumn of the same year he had the satisfaction of removing the last difficulties which hindered the marriage of William and Mary, an event which seemed to complete the work of 1668 and 1674. Louis still remaining obstinate in his demands, Temple was commissioned in July 1678 to make an alliance with the states, with the object of compelling France to come to terms. This treaty was instrumental in bringing about the general pacification which was concluded in January 1679.

This was Temple's last appearance in the field of diplomacy; but his public life was not yet over. A third offer of the secretaryship was made to him; but, unwilling as ever to mix himself up with faction and intrigue, he again declined. He did not, however, withdraw from politics; on the contrary, he was for a short time more prominent than ever. The state was passing through a grave crisis. Political passion was embittered by religious fanaticism. Parliament was agitated by the popish plot, and was pressing on the Exclusion Bill. The root of all the mischief lay in the irresponsibility of the cabinet to parliament and its complete subservience to the crown. To remedy this, Temple brought forward his plan for a reform of the privy council. This body was to consist of thirty members, half of whom were to be the chief officers of the crown, the other half being persons of importance, lords and commoners, chosen without reference to party. Special care was taken to select men of wealth, which Temple considered as the chief source of political influence. By the advice of this council the king promised to act. The parliament, it was supposed, would trust such a body, and would cease to dictate to the crown. The scheme was accepted by the king, but was a failure from the outset. Intended to combine the advantages of a parliament and a council, it created a board which was neither the one nor the other. The conduct of affairs fell at once into the hands of a junta of four, of whom Temple was at first one, and the king violated his promise by dissolving parliament without asking the advice of the council. Temple retired in disgust to his villa at Sheen, and appeared only occasionally at the council, where he soon ceased to exercise any influence. In 1680 he was nominated ambassador to Spain, but stayed in England in order to take his seat in parliament as member for the university of Cambridge. He took no part in the debates on the great question of the day, and acting on the king's advice declined to sit in the parliament of 1681. Early in that year his name was struck off the list of the council, and henceforward he disappeared from public life. He continued to live at Sheen till 1686, when he handed over his estate there to his son, the only survivor of seven children, and retired to Moor Park in Surrey. When William III. came to the throne Temple was pressed to take office, but refused. His son became secretary at war, but committed suicide immediately afterwards. Sir William, though occasionally consulted by the king, took no further part in public affairs, but occupied himself in literature, gardening and other pursuits. It should not be omitted that Swift lived with him as secretary during the last ten years (with one short interval) of his life. Temple died at Moor Park on the 27th of January 1699.

Temple's literary works are mostly political, and are of considerable importance. Among them may be mentioned *An Essay on the Present State and Settlement of Ireland* (1668); *The Empire, Sweden*, &c., a survey of the different Governments of Europe and their relations to England (1671); *Observations upon the United Provinces* (1672); *Essay upon the Original and Nature of Government* (1672); *Essay upon the Advancement of Trade in Ireland* (1673). Some of these were published in the first part of his *Miscellanea* (1679). In the same year apparently his *Poems* were privately printed. In 1683 he began to write his *Memoirs*. The first part, extending from 1665 to 1671, he destroyed unpublished; the second, from 1672 to 1679, was published without his authority in 1691; the third, from 1679 to 1681, was published by Swift in 1709. In 1692 he published the second part of his *Miscellanea*, containing among other subjects the essay *Upon the Ancient and Modern Learning*, which is remarkable only as having given rise to the famous controversy on the "Letters of Phalaris." His *Introduction to the History of England*, a short sketch of English history to 1087, was published in 1695. Several collections of his letters were published by Swift and others after his death.

His fame rests, however, far more on his diplomatic triumphs than on his literary work. His connexion with domestic affairs was slight and unsuccessful. He was debarred both by his virtues and his defects—by his impartiality, his honesty, and his want of ambition—from taking an active part in the disgraceful politics of his time. But in the foreign relations of his country he was intimately concerned for a period of fourteen years, and in all that is praiseworthy in them he had a principal hand. He cannot be called great, but he will be remembered as one of the ablest negotiators that England has produced, and as a public servant who, in an unprincipled age and in circumstances peculiarly open to corruption, preserved a blameless record.

See *Life and Works of Sir William Temple* (2 vols., 1720; 2nd ed., with *Life* by Lady Giffard, 1731); a more complete edition, including the *Letters*, was published in 4 vols. in 1814; Burnet, *History of his own Time*; T. P. Courtenay, *Memoirs of the Life, &c., of Sir William Temple* (2 vols., 1836); Macaulay, *Essay on Sir William Temple*; A. F. Sieveking, *Sir W. Temple and other Carolean Garden Essays*, (1908); and E. S. Lyttel, *Sir William Temple* (Stanhope Prize Essay, Oxford, 1908). (G. W. P.)

TEMPLE, a city of Bell county, Texas, U.S.A., about 35 m. S.S.W. of Waco. Pop. (1890) 4047; (1900) 7065 (1423 being negroes and 360 foreign-born): (1910) 10,993. It is served by the Gulf, Colorado & Santa Fé, and the Missouri, Kansas & Texas railways (the former has repair shops here), and is connected with Belton (pop. in 1910, 4164), the county seat, about 10 m. W., by an electric railway. In the city are a Carnegie library, a King's Daughters' Hospital, the Temple Sanitarium, and a hospital of the Gulf, Colorado & Santa Fé railway. Temple is situated in a rich farming country; cotton is ginned and baled here, and there are various manufactures. The city owns the water supply. Temple was founded in 1881–82 by the Gulf, Colorado & Santa Fé railway, and was chartered as a city in 1884.

TEMPLE, a term derived from the Lat. *templum* (Gr. *τέμενος*), which originally denoted a space marked off by the augurs for the purpose of observing the flight of birds or other ceremonies; later it was applied to the dwelling-place, the *aedes sacrae*, of the gods. In this latter sense it is the equivalent of the native Hebrew expression *bêth 'ĕlōhīm*, literally "a god-house," and of the foreign *hêkal*, palace, temple, a loan-word from Sumerian through the medium of the Babylonian *ê-kallu* (lit. great house). A temple or "god-house," however, represents a comparatively advanced stage in the development of Semitic religion. At first the Semite recognized the abodes of his deities in certain outstanding and impressive natural objects, a spreading tree, a bubbling spring, a conspicuous rock or stone, a lofty mountain peak and the like. Beside these he met and held converse with his gods. The native rock was the first altar.

It was a distinct step in advance when it was recognized that a deity might take up his abode elsewhere than in such natural sanctuaries, as in the *massebah* or stone pillar and the *ashērah* or sacred post of wood, reared not by nature but by the hand of man (cf. Gen. xxviii. 18, 22, the origin of the sacred pillar at Beth-el).

The further advance to a real house or temple may be traced to the influence of at least two factors in the social and religious life of a people. One such factor came into play when men began to represent the deity by means of an image, or even when some object, whether natural, like the black stone of Mecca, or manufactured, like the ark of the Hebrews, came to be regarded as specially sacred from its association with the deity. Such objects or images required a house to shelter and guard them. Another factor is to be found in the advance in material comfort which follows the transition from the nomadic to the agricultural mode of life. Among the settled Semites there arose the feeling that the gods of the community ought also to share in this advance (cf. 2 Sam. vii. 2). Accordingly they were invited to take up their abode in a *bêth 'ĕlōhīm* or temple. The dignity and comfort of the gods advance *pari passu* with those of their worshippers.

It must be kept in mind, however, that the altar remained as before the centre of the sacrificial worship. Around it or before it, under the open sky, the worshippers assembled. To the temple the priests alone, or the head of the sacral community in his priestly capacity, had access. In this respect the worship associated with altar and temple offers a striking contrast to the more spiritual worship of the Jewish synagogue and the Christian Church.

At the date of the Hebrew invasion of Canaan its numerous city-states had reached a fairly high level of civilization. Alongside of the typical Canaanite sanctuary, as known to us from the Old Testament references and from recent excavations, with its altar of earth or stone and its stately massebahs, a temple was probably to be found in all the more important centres. In an early Hebrew document there is a reference to the temple of El-berith at Shechem, which was large enough and strong enough to serve as a place of refuge in time of war (Judges ix. 46 ff.). The Philistines also had their temples in this period: thus we hear of a "house" of Dagon at Gaza (*ib.* xvi. 23 ff.) and also at Ashdod (1 Sam. v. 2), while a temple of Ashtart (Ishtar-Astarte) is mentioned in 1 Sam. xxxi. 10, probably at Ashkelon (Herod. i. 105).

The earliest reference to a temple built by Hebrew hands is to "an house of gods" reared by Micah to shelter an ephod and other sacred images which he had made (Judges xvii. 5). Micah's images were soon transported to Dan, where doubtless another house was built for their protection (xviii. 18, 30 f.). Somewhat later we find the ark of Yahweh installed in "the house of Yahweh" at Shiloh, which house was not a mere tent but a real temple (*hêkāl*, 1 Sam. i. 9, iii. 3) with doors (iii. 15) and doorposts (i. 9), and a hall in which the worshippers partook of the sacrificial meals (i. 18, Greek text; cf. ix. 22 "the guest-chamber," Heb. *lishkāh*). After the destruction of Shiloh at the hands of the Philistines, its priesthood migrated to Nob, where also the incidents recorded in 1 Sam. xxi.—note especially the presence of the shew-bread and the ephod—imply the existence of a temple.

The Temple of Solomon.—The primary source of our information regarding the erection of Solomon's temple is the account contained in 1 Kings vi.–vii., the details of which must have been derived ultimately from the temple archives. On this earlier narrative the chronicler (2 Chron. iii.–iv.) and Josephus (*Antiq.*, VIII. iii. 1 ff.) are alike dependent.

Unfortunately these two chapters of Kings are among the most difficult in the Old Testament, partly by reason of our ignorance of the precise meaning of several of the technical terms employed, partly owing to the unsatisfactory state of the received text, which has been overlaid with later additions and glosses. As regards both text and interpretation, most recent writers have adopted in the main the results of Stade's epoch-making essay in his *Zeitsch. f. d. alttest. Wissenschaft*, iii. (1883), 129–177, reprinted in his *Akademische Reden*, &c., with which is now to be compared Stade and Schwally's critical edition of Kings in Haupt's *Sacred Books of the Old Test.* See also, in addition to the standard commentaries, Burney, *Notes on the Heb. Text of . . . Kings*, Vincent's critical and exegetical study, *Rev. biblique* (Oct. 1907), and the literature cited at the end of this article.

(*a*) *The Site of the Temple.*—On this important point our earliest authority is silent. It is now universally acknowledged, however, that the whole complex of buildings erected by Solomon stood along the crest of the eastern hill, crowned by the temple at the highest point, as Josephus expressly testifies (*Bell. Jud.*; V. v. 1, with which compare the letter of (Pseudo) Aristeas, sect. 84). This at once brings the site of the temple into proximity to the world-famous sacred rock, the *sakhra*, over which now stands the building known as the Mosque of Omar, and, more correctly, as the Dome of the Rock. Here another important consideration comes to our aid. From the recognized persistence of sacred sites in the East through all the changes in the dominant religion, it is well-nigh certain that the sanctity of the *sakhra* rock goes back to the days of David and Solomon, or even, it may be, to prehistoric times. On it, or over it, the angel was believed to have been seen by David, and there David built his altar (2 Sam. xxiv. 18-25; cf. Judges vi. 20 f., 24; xiii. 19 ff.). This is undoubtedly the site assigned to the temple by the oldest extant tradition (see 1 Chron. xxii. 1; cf. 2 Sam. xxiv.). By every token, then, Solomon's altar of burnt-offering, if it was not identical with the *sakhra* (see below), at least stood upon it. Since the altar necessarily stood in front, *i.e.* to the east, of the temple, *the site of the latter was a short distance to the west of, and in line with, the sacred rock* (see JERUSALEM).

The alternative view, associated in recent times with the names of Schick and Conder, which places the most holy place, or innermost shrine of the temple, over the *sakhra*, has now few advocates (*e.g.* Col. Watson in the *Quarterly Statement* of the Palestine Exploration Fund for 1896 and 1910). Apart from difficulties of space towards the east, which this location involves, it cannot be accepted in face of the fact that the *sakhra* still bears the marks of its former use as a rock-altar (see esp. Kittel, *Studien zur hebr. Archäologie*, 12 ff.). Moreover the rock, measuring as it does some 55 ft. by 40, could not have been contained within the "holy of holies," which was less than 30 ft. square (see below).

A third site, still within the present Haram area, but towards its south-west angle, favoured by Fergusson (*The Temples of the Jews*), Robertson Smith (*Ency. Brit.*, 9th ed., art. "Temple") and others is open to even more serious objection, and has no prominent advocate at the present day.

(*b*) *The Temple Building.*—In the fourth year of his reign Solomon "began to build the house of the Lord" with the laying of a massive foundation of "great stones," as required by the rapid fall of the ground to the west of the *sakhra*. Architecturally the temple consisted of three distinct parts: (1) the *naos* or temple proper, (2) a porch or pylon in front of the naos, and (3) a lower and narrower building which surrounded the naos on its other three sides (see fig. 1).

(1) The first of these, "the house of the Lord" in the strict sense, in which alone He was worshipped, was oblong in plan, and was divided into two compartments in the proportion of 2 : 1 by a partition wall. The room next the porch was 40 cubits in length by 20 in breadth, with a height of 30 cubits,[1]

[1] The length of the cubit at this period cannot be determined with absolute certainty. From the fact that Herod's naos was an exact replica of Zerubbabel's as regards inside measurements, coupled with the presumption that Zerubbabel built upon Solomon's foundations, it is permissible to suppose that one and the same standard of length was used throughout. Now the present writer has shown from an inductive study of the height of the courses in the walls of the Haram and of other existing remains of the Herodian period that the cubit used by Herod's builders was exactly 17·6 in. or 447 millimetres (see *Expository Times*, xx. [1908–09] 24 ff.). There is therefore good reason for believing that this was also the cubit of Solomon's temple, notwithstanding the statement of 2 Chron. iii. 3 that the latter was a cubit "after

all *inside* measurements, and is termed in our oldest source the *hêkāl* or palace; later it was known as "the holy place." It was dimly lighted by a row of latticed windows, which must necessarily have been placed in the upper third of the side walls, as will presently be seen. Adjoining the hêkāl on the west lay the *dĕbîr* or sanctuary, later termed "the most holy place" (lit. "holy of holies"). The inside space formed a perfect cube of 20 cubits, say 30 ft., in length, breadth and height (vi. 20), symbolizing the perfection of the Deity, for whose abode this part of the naos was specially designed. The dĕbîr, as has been said, was separated from the hêkāl by a transverse wall, whose existence we are left to infer from the obscure description of the door between the two compartments (vi. 31, see next section).[1]

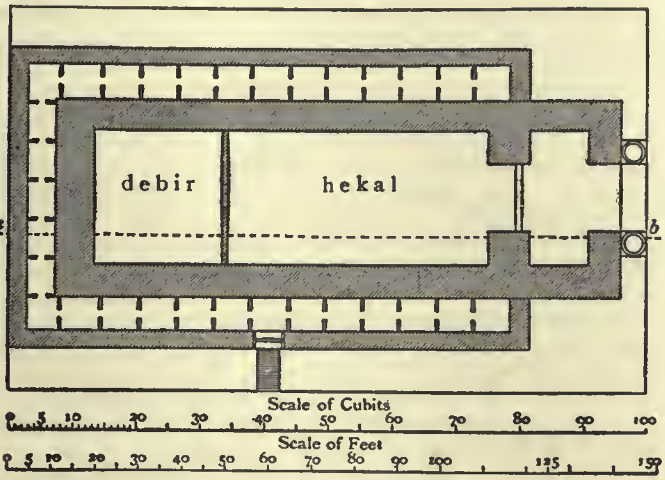

FIG. 1.—Ground Plan of Solomon's Temple.

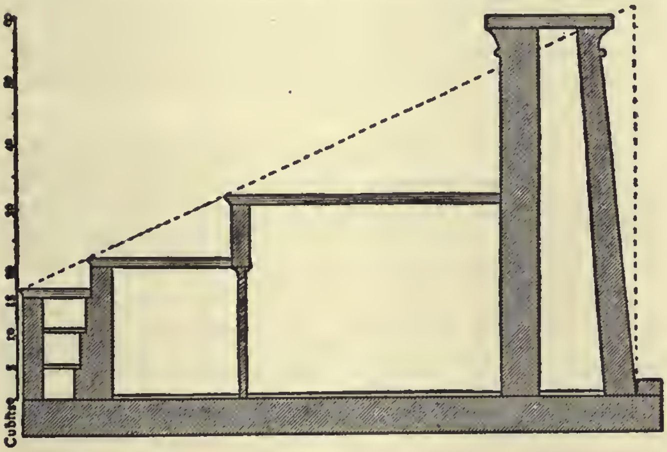

FIG. 2.—Section of Temple along *a–b* of Ground Plan.

(2) In front of the hêkāl and facing eastwards rose the porch, its inside "length" 20 cubits "according to the breadth of the house" (vi. 3), and its inside depth from east to west 10 cubits. The more precise character and elevation of this element will fall to be considered at a later stage.

(3) The third architectural element was a lateral building enclosing the naos on the other three sides, and consisting of three storeys, each 5 cubits in height from floor to ceiling. Each storey contained a number of small storage chambers, probably thirty in all (Ezek. xli. 6). A peculiarity in the architecture of this part of the temple is noteworthy. Instead of the beams forming the floors and ceilings of the several storeys being let into the wall of the hêkāl, three successive rebatements of one cubit each were made in the latter for their support (see fig. 2), consequently the width of the chambers was 5, 6 and 7 cubits in the three storeys respectively (vi. 6). The total height, allowing for floors and roof, of the lateral building cannot have been less than 17 cubits. Entrance to the side-chambers was provided by a single door on the south side (see ground-plan, fig. 1).

So far there is no difficulty as regards the general plan and dimensions of the temple, provided it is kept in mind that the figures given in the text of Kings are all inside measurements. It is otherwise when one endeavours to calculate the area covered by the temple, and to determine the elevation of the several parts and the general architectural style of the whole. As to the area much depends upon the thickness of the walls. Here our only clue is furnished by the figures for the corresponding walls of Ezekiel's temple, but the necessary caution has not hitherto been observed in applying them to the proportions of the actual temple of Solomon. It cannot be too strongly emphasized that in the dimensions of his temple of the future and its courts Ezekiel is dominated by a passion for symmetry and for the number 50 and its multiples,[2] which there is no ground for importing into the dimensions of the older temple. Nevertheless the walls of the naos may be taken at Ezekiel's figure of 6 cubits (xli. 5), with successive rebatements of one cubit (fig. 2) until the thickness is reduced to 3 cubits (4½ ft.) above the side-chambers, as explained above. If one cubit is allowed for the partition wall corresponding to the space in Herod's temple, where a curtain took the place of the wall, we obtain a total of 73 cubits for the length of the naos and of 32 for the outside width, or 107 ft. by 47. If 3 cubits—equal to the thickness of the wall of the naos above the side-chambers—be allowed for the outer wall of the latter, the extreme width of the temple works out at 48 cubits, or 70½ ft. Adopting Ezekiel's thickness of 5 cubits for the front wall of the porch, we reach a total of 96 cubits or 141 ft. for the extreme length from east to west (see the accompanying ground-plan). The proportion of length to breadth is thus 2 : 1, precisely as Ezekiel's temple with its artificial numbers of 100 and 50 respectively. The area of the platform on which Solomon's temple stood probably measured 100 cubits by 60, as in the plan annexed.

As regards the height of the various parts even fewer data are available. Our primary source gives the height of "the house" as 30 cubits (1 Kings vi. 2). By the great majority of previous students this has been understood to mean that a single flat roof, at this height from the floor, covered the three parts—porch, hêkāl and dĕbîr—leaving an empty space of 10 cubits above the last of these. But the Hebrew document, as has been repeatedly pointed out, is concerned only with inside dimensions, and in vi. 2 has probably in view the inside height of the hêkāl, as the largest of the three compartments. On the other hand, a characteristic feature of the contemporary Egyptian temples is the gradual diminution in the height of their component parts from front to back (Maspero, *L'Archéologie égyptienne* (1907), p. 77; Erman, *Handbk. of Egyptn. Religion*, 41; cf. the restoration of a typical temple in Perrot and Chipiez, *Anct. Egypt. Art.* i. 373, and in Erman, *Life in Anct. Egypt*, 280).

In this respect the present writer believes that Solomon's temple followed the Egyptian model, the height decreasing as one proceeded from the porch to the hêkāl, dĕbîr and side-chambers respectively. The porch, for instance, was probably modelled on the pylons which flank the principal entrance to an Egyptian temple, tall and narrow, with a sloping front wall surmounted by a cornice with its characteristic cavetto moulding. The 120 cubits which 2 Chron. iii. 4 gives as the height of the porch, followed by Josephus, *Ant.* XV. xi. 1 and elsewhere, seem to be out of proportion to the probable height of the rest of the building. But this objection does not apply to the 60 cubits given as the extreme height for the second temple in the trustworthy document, Ezra vi. 3.[3] This,

the former measure." For this statement is probably a mere inference from Ezek. xl. 5, where the divine messenger uses a cubit of seven handbreadths or 20½ in., the royal cubit of Egypt. For the smaller measurements the cubit of 17·6 in. may for greater convenience be reckoned at 1½ ft.

[1] If the view presented below as to the height of the various parts of the temple is accepted, this wall becomes a structural necessity, being required to support the back wall of the hêkāl.

[2] This has led Ezekiel certainly to increase the depth of his porch from 10 cubits to 12 (original text of Ezek. xl. 49), and probably to add a cubit to the thickness of the partition wall (xli. 3), in order to bring up the total length of his temple to 100 cubits.

[3] The numbers of this passage have been unnecessarily called in question by recent critics. The figures given are naturally those of the two extremes, which were not to be exceeded, viz. 60 cubits for the extreme height, that of the porch, and the same figure for the extreme width, that of the raised platform.

it may reasonably be inferred, was the height of the porch in the first temple, from which, in that case, the figure was derived. The probable outside measurements for the porch are thus 32 cubits for the breadth across "the house," 15 for the depth including the front wall, and 60 cubits or 88 ft. for the height.

Still following the Egyptian model, the hêkāl will have had its separate roof of massive cedar beams, covered probably by heavy limestone slabs, for which 1½–2 cubits may be allowed, giving a total of 32 cubits (47 ft.), equal to the outside width of this part of the temple. In the same way the roof of the dĕbîr will have been 10 cubits lower, or *circa* 32 ft. in all, that of the lateral building about 4 cubits lower still, say 26 ft. (cf. the section through the temple from W. to E. in fig. 2). While the measurements above given are, as they must necessarily be, in part conjectural, it is claimed for them that they introduce the element of proportion between the parts to an extent not attempted hitherto.

(*c*) *The Interior of the Temple and its Furniture.*—The entrance to the temple was through a wide and lofty opening in the front wall of the porch. Crossing the vestibule one entered the hêkāl by a large folding-door of cypress wood (vi. 34)—probably 10 cubits wide as in Ezekiel's temple—each of its four leaves ornamented with carved figures of cherubim, palms and flowers, all overlaid with gold. The inner walls of the hêkāl and the dĕbîr were lined with boards of cedar from floor to ceiling, while the floor was covered with planks of cypress wood.[1] From the hêkāl a door in the partition wall gave entrance to the dĕbîr. The doorway was not rectangular but apparently pentagonal in form (see the commentaries on vi. 31), the lintel consisting of two blocks of stone meeting at an angle, a feature "introduced to distribute the pressure of the superincumbent wall" (W. R. Smith).[2] The walls of the dĕbîr were overlaid with "pure gold" according to our present text (vi. 20); this enhancement of the dignity of the adytum as the earthly dwelling-place of the heavenly King is not so incredible as the profuse application of gold decoration to other and inferior parts of the house, even, as we have seen, to its floor (on this question see the critical works cited above).

As regards the furniture of the house, it is probable that the original text of 1 Kings introduced only the altar of cedar now found in the corrupt text of vi. 20, and to be identified with the table of shewbread, as the sole furniture of the holy place. The ten golden candlesticks, properly lampstands, of vii. 49 are generally believed to have been introduced at a later date (cf. Jer. lii. 18 f.). In the most holy place stood the palladium of Israel's religion, the sacred ark of Yahweh. On either side of this venerable relic of the past were two cherubim, sculptured from olive wood and overlaid with gold, each 10 cubits high, their outstretched wings reaching right across the dĕbîr, and forming a baldachin over the ark (vi. 23–28).

Although forming no part of the interior furniture of the temple, the remarkable twin pillars which stood on either side of the entrance to the porch may be mentioned here, since they belonged rather to the temple than to its court. These pillars, which in the received text bear the enigmatical names of "Jachin and Boaz,"[3] were hollow columns—the bronze metal being about 3 in. in thickness—over 26 ft. in height and 6 ft. in diameter, surmounted by elaborate capitals about 7½ ft. high. The latter were globular in form, ornamented by a specially cast network of bronze, over which were hung festoon-wise two wreaths of bronze pomegranates, each row containing a hundred pomegranates. As the pillars doubtless stood on plinths, the total height of each will have been at least 35 ft. Such free-standing pillars were a feature of temple architecture in Phoenicia and elsewhere in western Asia, as later reproductions on local coins attest, and would appear to Solomon's Phoenician architects as a natural adjunct of his temple. Jachin and Boaz, therefore, may be regarded as conventional symbols of the Deity for whose worship the temple was designed.[4]

(*d*) *The Temple Court, Altar and other Apparatus of the Cult.*—The temple stood within the western half of "the court of the house of the Lord," also known as "the inner court" to distinguish it from "the other court" round the adjoining palace and from "the great court" which surrounded the whole complex of Solomon's buildings. All three had walls in which three courses of hewn stone alternated with a course of cedar beams (see next section). To the "court of the house" laymen as well as priests had access (Jer. xxxv. 1 ff., xxxvi. 10). Several gates gave entrance to it, but their precise position is uncertain. The principal entrance from "the great court" was doubtless in the east wall. Another was in the south wall and communicated with "the other court" and the royal palace. There were also one or more gates on the north side of the court.

In our present text of 1 Kings vi.–vii., there is no mention of so indispensable a part of the apparatus of the cult as the altar of burnt-offering. This silence has been explained in two ways. The majority of critics believe that the original account did contain a reference to the making of a bronze altar (cf. 2 Chron. iv. 1), but that it was excised by a later editor, who assumed that the bronze altar of the tabernacle accompanied the ark to the new sanctuary. Others, with greater probability, maintain that the silence of our oldest source is due to the fact that Solomon followed the primitive Semitic custom and used the bare *sakhra* rock as his great altar. In this case the altar, which was removed by order of Ahaz to make way for his new altar after a Damascus model (2 Kings xvi. 10–16), must have been introduced by one of Solomon's successors.[5]

In the court, to the south of the line between the altar and the temple, stood one of the most striking of the creations of Solomon's Phoenician artist, Huram-abi of Tyre. This was the "brazen sea," a large circular tank of bronze with the enormous capacity of over 16,000 gallons (1 Kings vii. 23–26), resting on the backs of twelve bronze bulls, which, in groups of three, faced the four cardinal points.

It is doubtful if this strange "sea" served any practical purpose (see 2 Chron. iv. 6). Most recent writers agree in assigning to it a purely symbolical significance, like the twin pillars above described. Babylonian temples are now known to have had a similar apparatus, termed *apsu*, which symbolized either the primeval abyss, personified as the monster Tiamat subdued by Marduk, whose symbol was the bull, or, according to a later theory, the upper or heavenly sea, bounded by the Zodiac with its twelve signs.

Associated with the "brazen sea" were ten lavers of bronze, also the work of Huram-abi (vii. 27–39). Each laver consisted of a circular basin holding over 300 gallons, and borne upon a wheeled carrier or "base."[6] The sides of the carriers were open frames composed of uprights of bronze joined together by transverse bars or rails of the same material, the whole richly ornamented with palm trees, lions, oxen and cherubim in relief. Underneath each stand were four wheels of bronze, while on the top was fitted a ring or cylinder on which the basin rested. According to Kittel, "it is highly improbable that these lavers served any practical purpose. They were rather like the great 'sea,' the embodiment of a religious idea; they were symbols of the rain-giving Deity" (*op. cit.*, p. 242).

The Relation of the Temple to Contemporary Art.—Of the many problems raised by the description of the temple in 1 Kings none is of greater interest than the question of its relation to

[1] The overlaying of the floor with gold (1 Kings vi. 30) is a later interpolation; the same is probably true of the gilding of the sculptures on the walls, which may have been added at a later date (cf. Ezek. xli. 18).

[2] This partition wall, it will be remembered, had to support the back wall of the hêkāl according to the view of the temple architecture advocated above.

[3] The various forms which the latter name assumes, in the Greek text, suggest that Boaz is an intentional disguise of an original Baal, applied of course to Yahweh (Barnes, *Jour. of Theol. Studies*, v. 447 ff.).

[4] Robertson Smith's theory that they were huge cressets in which "the suet of the sacrifices" was burned (*Rel. Sem.*, 2nd ed., 488) has found no support. For recent attempts to explain the symbolism of the pillars in terms of the "early oriental *Weltanschauung*," see A. Jeremias, *Das alte Test.*, &c., 2nd ed., 494; Benzinger, *Heb. Archäol.*, 2nd ed., 323, 331.

[5] For a detailed study of the successive altars that stood upon the *sakhra* and their relation thereto, see Kittel, *Studien zur hebr. Archäologie*, pp. 1–85, with illustrations and diagrams.

[6] This section of Kings is peculiarly difficult, and has been made the subject of a special study by Stade in his *Zeitschrift* (1901), 145 ff. (cf. "Kings" in Haupt's critical edition), and more recently by Kittel, *op. cit.*, pp. 189–242, with illustrations of similar apparatus found in Cyprus and Crete.

contemporary art. Where, it has often been asked, shall we look for the model or prototype of the temple edifice? Whence were derived the *motifs* to be seen in its decoration? What influences can be detected in the elaborate apparatus above described? Now it has for long been recognized that Syria, including Phoenicia and Palestine, was from the earliest times the meeting-place of streams of influence, religious, artistic and other, issuing from the two great fountains of civilization and culture in the ancient world, Egypt and Babylonia. To these must now be added the early civilization of the Aegean as revealed by the excavations in Crete, and the later but highly developed culture of the Hittites. As a result the art of Phoenicia and Syria, originally borrowed from Egypt mainly, had by the 10th century become thoroughly eclectic. Of this syncretism the best illustration is furnished by the masterpieces of contemporary art, for which Solomon was indebted to Phoenician architects and Phoenician artists. Thus the general disposition of the temple with its walled court, porch or vestibule and naos has been shown by modern excavation, and by later representations on coins, to be characteristic of Phoenician and North Syrian temple architecture. Here, however, we have an adaptation of the earlier temple architecture of Egypt. Egyptian influence is most clearly seen in the gradual decrease in the illumination of the several parts. In the temple court, as in its Egyptian counterpart, men worshipped under the bright eastern sky; in the covered porch there was still no door to exclude the light which streamed in through the lofty entrance. But in the holy place only a dim light was admitted through latticed windows high up in the side walls, while the holy of holies, like the Egyptian *cella*, was completely dark.[1]

The sculptured panels of the interior were shown by Robertson Smith (*Ency. Brit.*, 9th ed., art. "Temple") to reveal familiar Phoenician motives, although Babylonia is probably the ultimate home of the cherubim. Excavations at Sinjirli in Northern Syria and at Megiddo have, further, solved the problem of the "three rows of hewn stones and a row of cedar beams" which was the architectural feature of the walls of the various courts (1 Kings vii. 12).[2] The use of wooden beams alternately with courses of stone was a familiar expedient in early times. The practice of building walls with recurring rebatements has also been illustrated by the recent excavations.

While the prototype of the temple itself is to be sought, as has been said, in Egypt, Babylonian influence is clearly traceable in the symbolical "brazen sea," the *apsu* of contemporary Babylonian, and doubtless also Phoenician, temples. The bronze lavers, finally, have been found to be dependent, both in their construction and in the *motifs* and execution of their reliefs, on the art of the Aegean. From Crete and Cyprus they passed through Phoenician intermediaries to Syria and Palestine. The temple of Solomon, in short, is a product of the best Syro-Phoenician art of the period, itself the product of ideas which had their source in other lands.

The Temple of Zerubbabel.—In the year 586 B.C. the temple of Solomon was committed to the flames by order of Nebuchadrezzar (2 Kings xxv. 8; Jer. lii. 12 f.). Seventy years later its successor was finished and dedicated, the foundation having been laid in the second year of Darius Hystaspes (520) during the governorship of Zerubbabel (Hag. ii. 18). There is every reason for assuming that the massive foundation courses of the earlier temple were still *in situ*, and available for the new building.[3] The latter's inferiority, attested by Hag. ii. 3, was rather in respect of its decoration and equipment, as compared with the magnificence of the first temple, than as regards the size of the building. The dimensions given in the royal decree (Ezra vi. 3)—60 cubits for height and the same for breadth—probably refer, as was pointed out in a previous section, to the extremes of height and breadth applicable to the porch and platform respectively. In these and most other respects it may be supposed that Zerubbabel's builders followed the lines of Solomon's temple. It is probable, however, that the walls of the naos, including both the holy and the most holy place, were now raised to a uniform height, the separate back wall of the former having been abolished and the naos covered by a single roof. This seems a legitimate inference from the absence in the second and third temples of a supporting partition wall within the naos. Its place, as separating the two compartments, was taken by a magnificent curtain or "veil," which is mentioned among the spoils carried off by Antiochus Epiphanes (1 Macc. i. 22).[4]

In the matter of the sacred furniture, the holy place contained from the first the table of shewbread, and one golden "candlestick" or lampstand in place of the ten which illuminated the hêkāl in the later days, at least, of the first temple (Jer. lii. 19). The golden altar of incense, which fell a prey with the rest of the furniture to Antiochus (1 Macc. i. xxi. f.) was probably introduced later than the time of Zerubbabel, since a Jewish author, writing in the 3rd century B.C. under the name of Hecataeus of Abdera, mentions only "an altar and a candlestick both of gold," and it is natural to identify the former with the gold-plated table of shewbread.[5] In one important respect the glory of the second house was less than that of the first. The holy of holies was now an empty shrine, for no one had dared to construct a second ark.

The second temple also differed from the first in having two courts, an outer and an inner, as prescribed by Ezekiel for his temple of the future. The outer court formed a square, each side of which was 500 cubits in length, also as prescribed by Ezekiel, with the *sakhra* rock in the centre (see *Exp. Times*, xx. 182). Within the inner court stood the altar and the temple. The former, as described by Hecataeus, was composed of white unhewn stones (cf. Exod. xx. 25), "having each side 20 cubits long, and its height 10 cubits" (Josephus, *Contra Apion.* i. § 198), dimensions which agree with those assigned by the chronicler to the earlier altar of bronze (2 Chron. iv. 1).

In 165 B.C., three years after the spoliation of the temple and the desecration of its altar by Antiochus IV., Judas Maccabaeus rededicated the holy house, made new sacred furniture, and erected a new altar of burnt-offering (1 Macc. iv. 41 ff.). But long before this date the temple had assumed a character which it retained to the end of the Jewish state. It had become a fortress as well as a place of public worship, and existing records tell of the repeated strengthening of its defences. "At the time of Pompey's siege (63 B.C.) it constituted an almost impregnable fastness, strengthened on its weakest or northern side by great towers and a deep ditch (*Ant.*, xiv. 4, § 2). Twenty-six years later the temple was again besieged by Herod, who, attacking like Pompey from the north, had to force three lines of defence—the city wall, and the outer and inner temple," *i.e.* the walls of the outer and inner courts (W. R. Smith).

The Temple of Herod.—In the 18th year of his reign (20–19 B.C.) Herod obtained the reluctant consent of his subjects to his ambitious scheme for rebuilding the temple and for enlarging and beautifying its courts. The former was finished in eighteen months by a thousand priests trained for this special purpose, the courts in eight years, but the complete reconstruction occupied more than eighty years, lasting almost till the final breach with Rome, which culminated in the destruction of the sacred edifice by the soldiers of Titus in A.D. 70.

[1] This feature gives valuable support to the view presented above that Solomon's temple resembled its Egyptian contemporaries in an equally striking characteristic, the decrease in height with the decrease in illumination.

[2] This description possibly applies to all the buildings (note verse 9), including the temple itself, and was so understood by the writer of Ezra vi. 4.

[3] From Hag. i. 8. Driver indeed infers that "there would probably be almost sufficient stonework remaining [for all purposes] from Solomon's temple" (*Cent. Bible in loc.*).

[4] M. Clermont-Ganneau has put forward the interesting conjecture that the veil presented by Antiochus to the temple of Zeus at Olympia (Pausanias, V. xii. 4) was that taken from the temple at Jerusalem (see "*Le Dieu satrape*," &c., in the *Journ. asiatique*, 1878).

[5] The witness of the Pseudo-Hecataeus and of another Jewish Hellenist, the Pseudo-Aristeas, regarding the second temple has recently been examined by G. A. Smith in his volumes on Jerusalem (see esp. index to vol. ii., and cf. Vincent, "Jérusalem d'après la lettre d'Aristée," *Rev. biblique* (1908), 520 ff. (1909), 555 ff.).

(*a*) *The Outer Court, its Gates and Colonnades.*—The outer court of Zerubbabel's temple (500×500 cubits) was doubled in area according to Josephus (*Bell. Jud.* I. xxi. 1). The extension was principally on the south, which involved enormous substructions on both sides of the hill, in order to secure the necessary level surface. There can be little doubt that this part of the present Haram area with its containing walls is essentially the work of Herod. The northern boundary of this great court, termed "the mountain of the house" in the Mishnah, and now generally known as "the court of the Gentiles," remained as before, and is represented by a line of scarped rock immediately to the north of the present inner platform of the Haram. This line of scarp, when prolonged east and west for about 1000 ft. in all, meets the east wall of the Haram a little to the north of

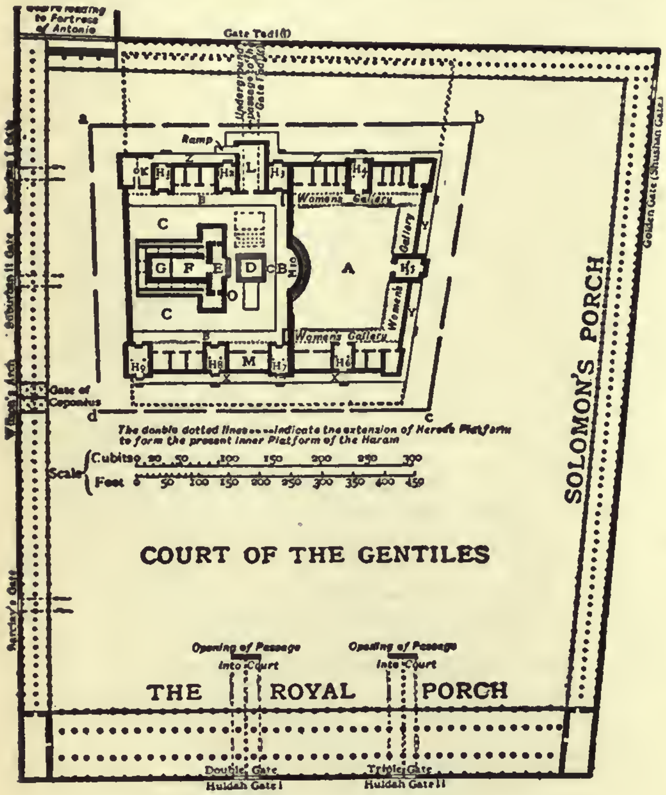

FIG. 3.—Plan of Herod's Temple and Courts.

From the *Dictionary of the Bible* (1909),[1] by kind permission of T. & T. Clark.

the Golden Gate, at a point 390 yds. (800 cubits) from the S.E. angle, and the west wall at the same distance from the S.W. angle.[2]

The principal entrance to the temple enclosure, and the only one on a level with it, was on its western side by a bridge or viaduct which spanned the Tyropoeon at the spot marked by Wilson's arch. It is first mentioned in connexion with the siege of Pompey in 63 B.C., and according to the Mishnah it bore the name of the Gate of Kiponos (probably Coponius, the first procurator of Judea). Of the other three gates which Josephus assigns to this side (*Ant.* XV. xi. 5), the two leading to "the suburb" necessarily lay further north; one is represented by the old entrance now named Warren's gate, the other has not been identified. Josephus' third gate which led to the "other" or lower city was undoubtedly Barclay's gate, and not, as is usually maintained, an entrance from Robinson's arch. In the south wall were two gates—the Huldah or "mole" gates of the Mishnah (*Middoth*, i. 3)—represented by the present "double" and "triple" gates. Like the three last mentioned they had to be placed at the foot of the lofty retaining wall. From either gate a double ramp, which passed under the royal porch, led into the court in the direction shown on the accompanying plan. The Mishnah also names the "Shushan gate" on the east and the "Tadi gate" on the north.

Round the four sides of the great court ran a succession of magnificent porticoes in the style of contemporary Hellenistic architecture (*Ant.* XV. xi. 5). Those on the E., N. and W. sides had each three rows of columns forming a double walk or aisle; the eastern colonnade bore the old name of "Solomon's Porch" (John x. 23; Acts iii. 11). The southern portico was still more imposing and magnificent.

It had three aisles formed by four rows of monolithic marble columns of the Corinthian order,[3] the first row engaged in the south wall of the court. The two side aisles were 30 ft. in width, the central aisle half as wide again (45 ft.); the height of the former may be estimated at *circa* 60 ft., that of the latter at 100 ft. (*Exp. Times*, xx. 68 f.). The roofs were formed of deeply coffered cedar beams, that of the centre aisle being supported on pillars partly engaged in an ornamental stone balustrade. The "royal porch," as it was termed, worthily represents the high-water mark of Herod's architectural achievements in connexion with the reconstruction of the temple.

(*b*) *The Inner Courts and Gates.*—To the outer court Jew and Gentile, under certain conditions, had alike access. The sanctuary proper, from which the Gentile was rigidly excluded, began when one reached the series of walls, courts and buildings which rose on successive terraces in the northern half of the great enclosure. Its limits were distinguished by an artistic stone balustrade, named the *sōrēg*, which bore at intervals notices in the Greek tongue warning all Gentiles against advancing further on pain of death. Beyond the *sōrēg* a narrow stone terrace, approached by flights of steps, was carried round all sides of the sanctuary save the west (see *Bell. Jud.* V. i. 5 [§ 38]), and extended to the foot of the lofty fortified walls of the temple enclosure (see X Y Z on plan, fig. 3).

The walls, over 35 ft. in height (25 cubits), were pierced by nine gateways, marked H1 to H9 on the accompanying plan, of which four were in the north and south walls respectively, and one in the east wall. These nine gates opened into massive two-storeyed towers, each 30 cubits deep (*Bell. Jud.* V. v. 3). Eight were "covered over with gold and silver, as were also the jambs and lintels" (ibid.), while the ninth, the principal entrance to the sanctuary, in the east wall (H5) was composed entirely of Corinthian brass, the gift of a certain Nicanor. Hence it was variously named "the Corinthian gate," "the gate of Nicanor" and "the beautiful gate" (Acts iii. 2, 10).[4]

Entering the sacrosanct area by this gate one found oneself in a colonnaded court, known as the court of the women (A) since women as well as men were admitted to this court, which indeed was the regular place of assembly for public worship. The four corners of the women's court were occupied by large chambers for various ceremonial purposes, while between these and the gate-houses were smaller chambers, one set being known as "the treasury" (Mark xii. 42). The western side was bounded by a high wall, beyond which, on a higher level, lay the inner or priests' court. The entrance to the latter was by an enormous gateway, 50 cubits by 40, through which an uninterrupted view was obtained of the altar and of the temple beyond it. To this "upper gate"

[1] Which see for key to the several parts.

[2] The area of the "court of the Gentiles," including the walls, was thus 800 cubits in length from N. to S., with an average width of *circa* 650 cubits of 17·6 in.—the present south wall measures 922 ft.—*i.e.*, *circa* 520,000 sq. cubits as compared with the former area of 250,000, a remarkable confirmation of Josephus' statement as to the doubling of the temple courts. For the statements and measurements in this and the following sections differing from those of previous writers, reference may be made to the series of preliminary studies entitled "Some Problems of Herod's Temple," by the present writer, which appeared in *The Expository Times*, vol. xx (1908–1909), pp. 24 ff., 66 ff., 181 ff., 270 ff.

[3] One such gigantic monolith was discovered a few years ago in a disused quarry (see *Exp. Times*, xx. 69).

[4] For this triple identification see Schürer's essay, *Zeits. f. neutest. Wiss.* (1906), 51–58; Berto, *Rev. des études juives*, lix. (1910), 30 f.; also *Exp. Times*, xx. 270 f.

(H10) a flight of fifteen semicircular steps led up from the court of the women.

On a level with the entrance and running round three sides of the inner court (so Josephus) was a narrow strip (B), about 18 ft. broad, called the "court of the men of Israel." The rest of the oblong area, however, was reserved for the priests and such of the laity as might require admission for the offering of their sacrifices. As in the lower court, the spaces between the gates were occupied by chambers, as to the purpose of which details are given in the Mishnah.

With regard to the more precise location of these temple courts, the present writer in the series of essays above referred to (see esp. *Exp. Times*, xx. 181 ff.),[1] has endeavoured to prove that the *whole fortress-sanctuary within the great walls stood on what is now the inner platform of the Haram*, the present extended area of which is indicated by the double dotted line on the plan.

According to the Mishnah (*Middoth*, ii. 5, 6) the upper and lower courts together formed a rectangle measuring 322 cubits from west to east by 135 cubits from north to south, the upper court 187 by 135, the lower 135 by 135. But, on the one hand, no account is taken of the gate-towers and priests' chambers which lined the courts, and on the other, the frequent recurrence of the number 11 and its multiples in the details which make up the above totals awakens suspicion as to their accuracy. The measurements of the accompanying plan are based on a critical comparison of the data of the Mishnah and those of Josephus with the relation of the whole to the altar on the *sakhra* (see next section). The total area covered by the sanctuary, including the terrace or *khēl*, is entered as 315 cubits (462 ft.) across the rock from west to east, and 250 cubits (367 ft.) from north to south (for the detailed measurements see *Exp. Times*, xx. 181 ff., 271 ff.). The upper court shows an area of 170 cubits by 160, the lower court has a free space between the colonnades of 135 cubits (the Mishnah figure) by an average width of 110 cubits.

(*c*) *The Altar of Burnt-offering.*—Herod's great altar (D on the plan) was formed of unhewn stones, like that which preceded it. Its size, however, was increased till it formed a square, each side of which measured 32 cubits or 47 ft. at the base, thus occupying almost the whole of the exposed surface of the *sakhra*. The sides of the square decreased upwards by three stages until the altar-hearth was only 24 cubits square. The priests went up by an inclined approach on the south side (cf. Exod. xx. 26). To the north was the place where the sacrificial victims were slaughtered and prepared for the altar (cf. Levit. i. 11). It was provided with rings, pillars, hooks and tables. A laver (O on the plan) for the priests' ablutions stood on the west of the altar ramp.

(*d*) *The Temple Building.*—A few yards to the west of the altar rose the temple itself, a glittering mass of white marble

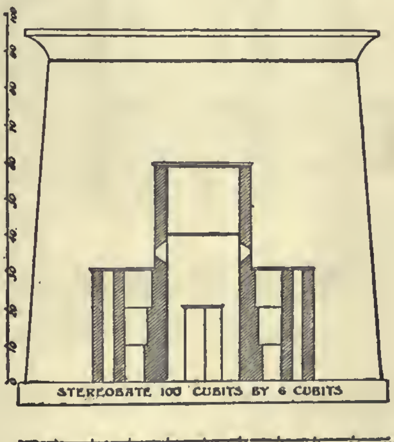

FIG. 4.—Diagrammatic Section of Herod's Temple and Porch.

and gold. Twelve steps, corresponding to the height (12 half-cubits) of the platform, led up to the entrance to the porch. In the disposition of its parts Herod's temple was in all essential respects a replica of its two predecessors. But there were differences in details. Thus the porch was increased in width and height until its front elevation measured, according to our authorities, Josephus and the Mishnah, 100 cubits by 100. This, however, probably includes the platform, as the principles of proportion in relation to the other dimensions suggest 96 cubits by 96 (over 140 ft.) as the actual measurements. In shape the porch may be supposed to have retained its original likeness to an Egyptian pylon, as suggested in the accompanying diagram (fig. 4).

The holy place (F) retained its former area (40×20 cubits), but was raised in height to 40 cubits. A magnificent double curtain, embroidered in colours, screened off the most holy place, which remained a perfect cube of 20 cubits each way. By introducing a passage-way giving access to the side-chambers and requiring an extra outer wall, Herod increased the width of the temple building to at least 60 cubits (70 according to the Mishnah). The problem of the height of the naos remains almost as perplexing as before. Josephus, it is true, agrees with the Mishnah (*Middoth*, iv. 6) in giving it a height of 100 cubits. It may be that Herod, "if he was forbidden to extend the House, would at least make it soar!" (G. A. Smith). But the details given by the Jewish doctors do not inspire confidence, for, as Fergusson long ago perceived, "one storey is merely an ill-understood duplication of the other." A more modest height of 60 cubits (88 ft.), equal to the extreme width, gives at least an element of proportion to the edifice which is altogether wanting in the traditional figures (compare the accompanying cross section, fig. 4).

The open entrance to the porch now measured 40 cubits by 20, equal to the section of the holy place. The "great door of the house," 20 cubits high and 10 wide, was covered with gold; in front was suspended a richly embroidered Babylonian veil, while above the lintel was fixed a huge golden vine.

(*e*) *The Temple Furniture.*—This remained as before. In the holy place in front of the holy of holies, still a dark and empty shrine, stood the altar of incense, against the south wall the seven-branched golden lampstand, and opposite to it the table of shewbread. The two latter, as every one knows, were carried to Rome by Titus, and representations of them may still be seen among the sculptures adorning the arch which bears his name.

When one considers the extraordinary height and strength of the outer walls of the temple area, parts of which excite the wonder of every visitor to the holy city, the wealth of art lavished upon the wide-extended cloisters, the imposing character of the temple façade, and the impression produced by the marble-paved terraces and courts rising in succession, each above and within the other, one is not surprised that the temple of Herod was reckoned among the architectural wonders of the ancient world. There is for once no exaggeration in the words of Josephus when he records that from a distance the whole resembled a snow-covered mountain, and that the light reflected from the gilded porch dazzled the spectator like "the sun's own rays" (*Bell. Jud.* V. v. 6).

LITERATURE.—In addition to the primary sources, the Bible, Josephus, and the Mishnah treatise *Middoth* (ed. Surenhusius with commentaries), the commentaries and notes on Kings by Benzinger, Kittel, Stade, Burney and Skinner, the articles on the temples in the recent Bible Dictionaries and the "Archaeologies" of Benzinger and Nowack, the following should be consulted: De Vogüé, *Le Temple de Jérusalem* (1864); Jas. Fergusson, *The Temples of the Jews* (1878); Perrot et Chipiez, *Le Temple de Jérusalem* (1889); C. Schick, *Die Stiftshütte, der Tempel*, &c. (1896); W. Shaw Caldecott, *Solomon's Temple* (1906), and *The Second Temple*, &c. (1908); R. Kittel, "*Tempel*" and "*Tempelgeräte*" in Herzog-Hauck, *Realencyklopädie*, 3rd ed. (1907), vol. xix.; G. A. Smith, *Jerusalem*, 2 vols. (1908, see index to each vol.); also W. R. Smith's art. "Temple" in *Ency. Brit.*, 9th ed. For Herod's temple more especially see Maimonides' treatise *Beth Ha-bekhîra* (the chosen house), trans. in *Quart. Statement* of Pal. Explor. Fund (1885); and the recent studies by Watson, *ibid.* (1896 and 1910); Waterhouse in Sanday's *Sacred Sites of the Gospels* (1903); A. R. S. Kennedy, "Some Problems of Herod's Temple," *Expository Times*, vol. xx. (1908–1909); G. Dalman, "Der zweite Tempel zu Jerusalem," in the *Palästinajahrbuch* (1909); P. Berto, "Le Temple de Jérusalem," *Rev. des études juives*, lix.–lx. (Jan.–July 1910), and the articles in the *Jewish Encyclopaedia*. For the study of the site the works of the English surveyors (see JERUSALEM), including Sir C. Wilson's large-scale map of the Haram, are indispensable.

(A. R. S. K.)

[1] A summary of the results is given in the article "Temple" in Hastings' *Dict. of the Bible* (1909).

Egyptian Temples.—In the architectural sense the earliest temples in Egypt probably consisted only of a small cella, or sanctuary, with a portico, such as are represented in the models of soul-houses found in 1907 by Flinders Petrie at Rifeh; in front of these various additions were made, so that eventually the temple assumed far greater importance than was at first contemplated. This custom is at variance with that which takes place in the development of other architectural styles, where the older buildings are constantly taken down and rebuilt in accordance with the increased knowledge acquired in construction and design. It follows from this that although the Egyptian temples vary in their dimensions and extent, as a rule they present the same disposition of plan. The principal exceptions to this rule are the sepulchral temples, such as those of Deir el Bahri, and the more ancient example adjoining it, discovered in 1906, in which there are no enclosed halls of columns or sanctuary, and the Mammeisi temples (fig. 5), which in plan resemble the Greek peristylar temples and might have been suggested by them, had not the example at Elephantine (destroyed in 1822) been of much earlier date, having been built by Amenophis III. (1414–1379).

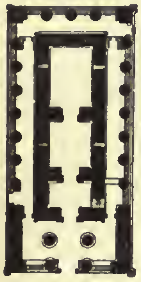

Fig. 5.—Plan of Mammeisi Temple, Philae.

The earliest example of which remains have been found is the temple built by Cephren in front of his pyramid at Memphis, and this consisted only of a sanctuary of small size without any architectural pretensions. The next in date would be the sepulchral temple built by Mentuhotep (2832–2796) adjoining Deir el Bahri at Thebes; then follows the sanctuary of Karnak, built by Senwosri (Usertesen) I. (2758–2714), which formed the nucleus of that immense temple, which covered an area of 400,000 sq. ft. This temple may be taken as an extreme type of the accumulation which is found in nearly all the Egyptian temples, owing to the additions made to the original structure by successive monarchs, instead of rebuilding, as was the general custom in all other styles. To a certain extent the same conservative principle seems to have governed the design of all other temples, and even the temple at Edfû, which was set out on a plan conceived from the first, has the appearance of having been added to at various periods, the fronts of the inner halls showing inside those built in front. It is not only in the plan that the close resemblance of one building to another is shown; the architectural design is repeated in the earliest and latest temples; the raking sides of the pylons and walls with the torus-moulding of the quoins and the cavetto cornice are identical, so that it is only by the inscriptions that one is able to ascribe the buildings to the kings of the 18th or following dynasties and distinguish them from those erected by the Ptolemies, or even under Roman rule. The only differences are those exhibited in the great halls of columns, which, in the earlier temples, were built in between the pylons and side walls, receiving their light through clerestory windows, as at Karnak (fig. 6), the other temples in its vicinity and the Ramesseum; whereas in the later temples

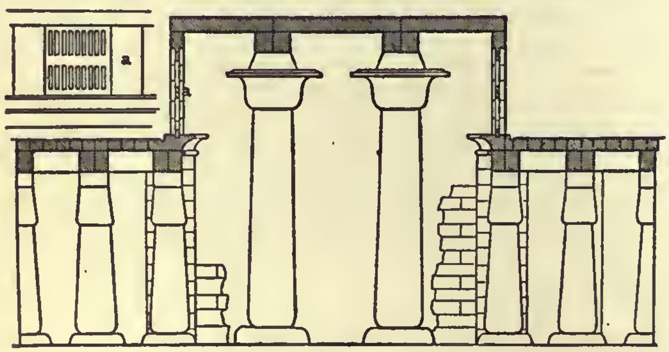

Fig. 6.—Hall of Columns, Karnak.

on one side of the walls a screen was built between the columns, over which the interior was lighted. The second change was that made in the capitals of the columns, which are of wonderful diversity of design, even in the same hall, including every variety of river plant, in addition to the papyrus and lotus flowers; in the later temples also the columns are more slender in their proportions and not set so closely one to the other.

Although generally the temples are built symmetrically on a central axis, with walls at right angles to one another, there are some special exceptions; thus the axial line of the great entrance court of the temple at Luxor is at an angle of about 15° with that of the temple in its rear, and in the island of Philae no two buildings are on the same axis or are parallel to or at right angles to one another, thus conforming to the irregular site on which they were built.

Assyrian.—The temple in Chaldaea or Assyria (known as a *ziggurat*) was of an entirely different class, and took the form of a many-storeyed structure, of which the typical example is the Birs Nimrud. This originally consisted of six storeys, each one set behind the other, so as to admit of a terrace round each, the upper storey being crowned by a shrine.

Access to the several storeys was obtained by flights of steps, either lying parallel with the front or in one continuous flight in centre of same, or again as at Khorsabad by a ramp winding round the tower; the architectural design consisted of sunk panels on the various storeys with battlement parapets, and, like the Birs Nimrud, the several storeys were dedicated to the seven planets, the walls being enriched with the colours sacred to each.

Greek and Roman.—In Greece the earliest example of a temple is that of the Heraeum at Olympia, ascribed by Dr Dörpfeld to the 10th century B.C. The Heraeum (fig. 7) consisted of

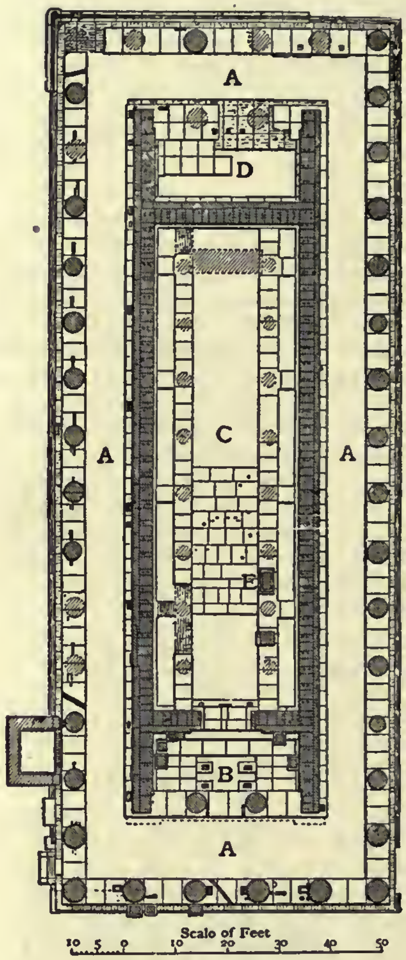

Fig. 7.—The Heraeum.

From Curtius and Adler's *Olympia*, by permission of Behrend & Co.

a central naos or sanctuary with pronaos in front and opisthodomus in the rear, the whole enclosed by a peristyle, thus presenting the characteristics of the fully developed temple of the 5th century. As, however, the description of the several types would be rendered clearer if they were taken from the simplest plan to the more elaborate, adopting to a certain extent the definitions given by Vitruvius, they are as follows:—

Distyle-in-antis, a cella or naos preceded by a portico of two columns placed between the prolongation of the cella wall. Fig. 8. The Temple of Themis Rhamnus.

FIG. 8.

FIG. 9.

FIG. 10.

FIG. 11.

Amphidistyle-in-antis, similar to the foregoing but with a second portico in the rear. Fig. 9. The Temple of Diana Propyloea, Eleusis.

Tetrastyle prostyle, with a portico of four columns in front. Fig. 10. The Temple B. Selinus, Sicily.

Tetrastyle amphiprostyle, with an additional portico of four columns in the rear. Fig. 11. The Temple of Nike Apteros, Athens.

Hexastyle peripteral, six columns in front and rear and a peristyle round the cella forming a covered passage round. Fig. 12. The Temple of Theseus, Athens.

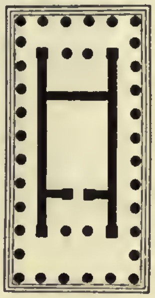

FIG. 12.

Octostyle peripteral, eight columns in front and rear and a peristyle round. FIG. 13. The Parthenon, Athens.

Octostyle dipteral, eight columns in front and rear and a double row in the peristyle. Fig. 14. The Temple of Jupiter Olympius, Athens.

Octostyle pseudo-dipteral, similar to the last, except that the inner row of columns is omitted, thus giving a passage round of twice the ordinary width. Fig. 15. The Temple of Apollo (Smintheus), Troad.

Decastyle dipteral, ten columns in front and rear and a double row in the peristyle. Fig. 16. The Temple of Apollo Didymaeus, at Branchidae, near Miletus.

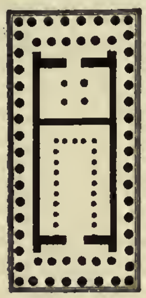

FIG. 13.

To these there are a few exceptions:—

Heptastyle pseudo-peripteral, seven columns in front and rear with walls built in between the outer range of columns, so that they were only semi-detached, as in the temple of Jupiter Olympius at Girgenti.

Enneastyle peripteral, nine columns in front and rear and a peristyle round as in the so-called Basilica at Paestum. Of circular temples there were two varieties:—

Monopteral, a series of columns built in a circle, but without any cella in the centre; and

Peripteral, with a circular cella in the centre. Fig. 17. The Philippeion, Olympia.

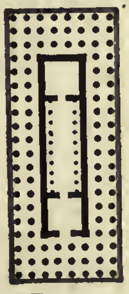

FIG. 14.

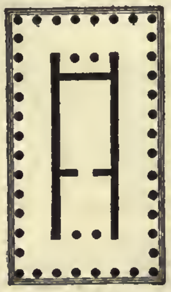

FIG. 15.

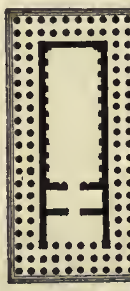

FIG. 16.

The above definitions apply to Greek temples, whether of the Doric, Ionic or Corinthian orders. The Romans in some of their temples adopted the same disposition, but with this important difference, that, instead of the temple resting on a stylobate of three steps, it was raised on a podium with a flight of steps in front. In some of their temples, requiring a larger cella wherein to store their works of art, it occupied in the rear the full width of the portico in front; they retained, however, the semblance of the peristyle, the columns of which became semi-attached to the cella wall. If the portico had four columns, the temple was known as *tetrastyle pseudo-peripteral*, of which the so-called temple of Fortuna Virilis at Rome is an example; and if six columns, *hexastyle pseudo-peripteral*, as in the Maison Carrée at Nîmes.

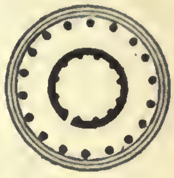

FIG. 17.

In front of the naos or cella of the Greek temple there was always a pronaos, viz. a vestibule with two or more columns *in antis*, and in the rear a similar feature known as the opisthodomus or treasury; in a few cases, as in the Parthenon, this formed a separate chamber, which was entered through a similar vestibule to that in front of the naos; this same vestibule in the absence of the separate chamber was sometimes enclosed with bronze grilles and used as the opisthodomus; the Latin term *posticum* is frequently given to this rear vestibule, for which the Germans and Americans have adopted the term *epinaos* when speaking of Greek temples. In Roman temples the posticum is rarely found; the portico, on the other hand, was increased in importance, being frequently the depth of three bays or columniations. In most of the early Greek temples the cellas were comparatively narrow, owing to the difficulty of roofing them over, as the Greeks do not seem to have been acquainted with the principle of the trussed beam. When therefore more than the usual width was required it became necessary to introduce columns on each side within the cella to carry the ceiling and roof, the earliest example of which existed in the Heraeum at Olympia. There are two other temples in which some of these internal columns still exist, as in the temples at Aegina and Paestum. At Aegina there were five columns on each side, carrying an architrave with five smaller columns superposed; in the temple of Neptune at Paestum there were seven on each side; and in the Parthenon nine columns and a square pier at the end with three columns in the rear, thus constituting an aisle on three sides, round which privileged visitors, like Pausanias, were allowed to pass, there being bronze rails between the columns. In the temple of Zeus at Olympia traces of the barriers have been found, as also of an upper gallery, access to which was given by a wooden staircase. The question of the lighting of these temples has never

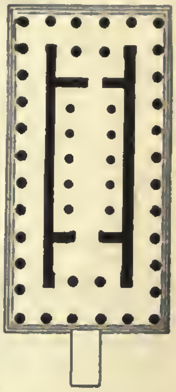

FIG. 18.

FIG. 19.—Temple of Aphaea at Aegina. West Front.

been definitely settled; it is probable that as a rule the only direct light received was that through the open doorway (see HYPAETHROS).

In the earliest temples, those of the Heraeum at Olympia, of Apollo at Thermon, and the archaic temple at Argos, the columns of the peristyle were in wood and carried a wooden architrave; in the Heraeum the wooden columns were replaced by columns in stone when they showed signs of deterioration; the earliest stone columns which were introduced date from the 6th century, and Pausanias in the 2nd century saw one wood column still *in situ* in the opisthodomus. From about the middle of the 7th century the columns were always in stone, and were generally built in several courses with drums or frusta, there being very few instances of monolith columns in Greek temples; the Romans, on the other hand, in their principal columns considered the monolith to be more monumental, and not only employed the finest Greek marbles to that end, but used granite and porphyry.

The favourite type of Greek temple was that known as hexastyle peripteral, of which the temple of Aphaea at Aegina, of the

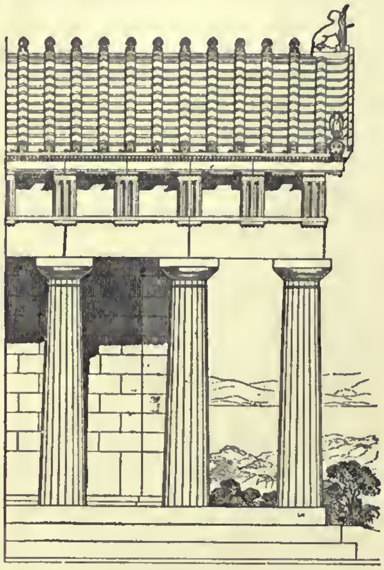

FIG. 20.

Doric order, is one of the best-preserved examples; on account of the width of its naos it was necessary to provide columns inside it to carry the ceiling and the roof, so that it represents the fully developed type of a Greek temple. The plan of the temple is shown in fig. 18; the elevation is given in fig. 19, representing the west front, the columns of which rest on a stylobate of three steps, and carry the entablature and pediment. Fig. 20 shows the three first columns of the flank elevation, the entablature carried by them, and the tiled roof with antefixa and crested ridge.

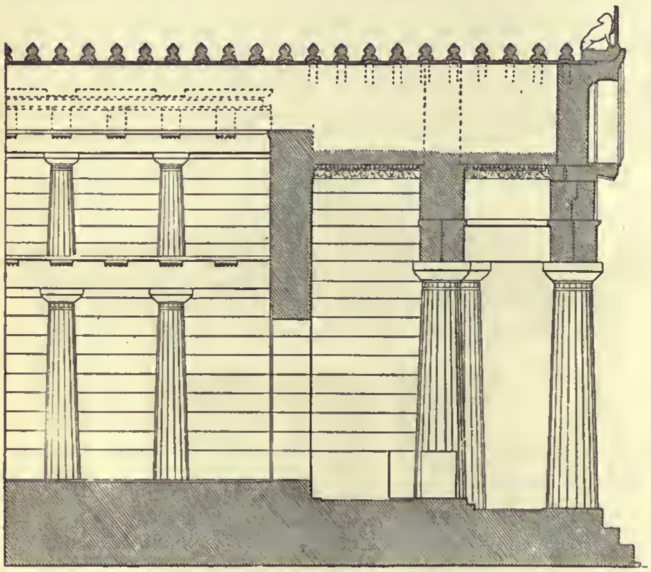

FIG. 21.

Fig. 21 gives the section through the stylobate, peristyle and pronaos, and half of the naos, showing the superposed columns, ceiling and roof, all based on the conjectural restoration by Cockerell. The temple of Aegina is supposed to have been erected about 500 B.C., the magnificent sculpture with which it is enriched being added *c.* 480 B.C. The temple was built of a fine calcareous stone from quarries close by, which was coated over with a thin layer of stucco of lime and marble dust; this enabled the masons to give finer profiles to the mouldings, and afforded a field for colour, of which the restoration is shown in Cockerell's *Temple of Aegina*, from which the illustrations are taken; the cymatium and the tiles covering the roof were in Parian marble.

The Greek Temples were always enclosed in a temenos, in which were other shrines, altars and treasuries; in Athens the temenos was the Acropolis, on which the temples were built; at Delphi it was in a valley on inclined ground; and in Girgenti the temples were raised on the ridge of a hill; in all these cases the Greeks accepted the inequalities of the site, and, adding art to nature,

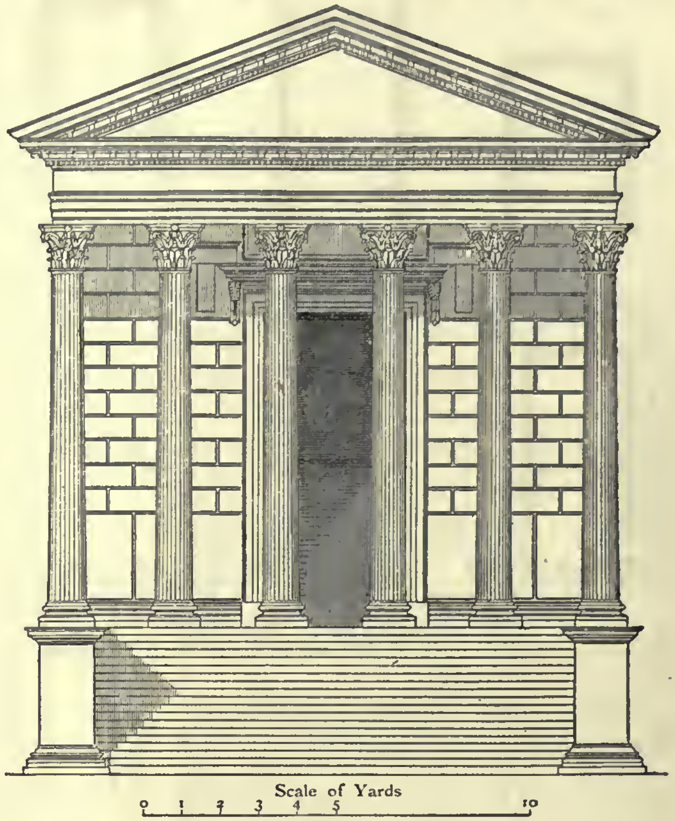

FIG. 22.

united their work with that of the Creator, so that it seemed to form part of the same design. Some of the sites of the temples, such as those at Olympia, Epidaurus and Delos, were practically level, but even in those the temples and other structures were arranged in groups, thus producing a much more picturesque effect than in those of the Romans, which, when enclosed, were always

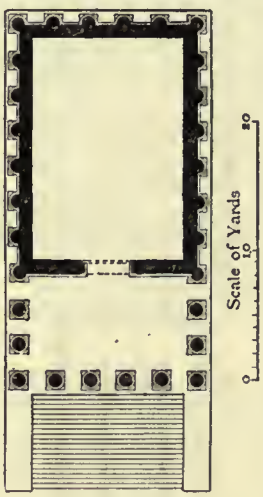

FIG. 23.

planned on axial lines and raised on artificial platforms or terraces, as at Baalbek, Palmyra and Aizani, with peristyles round the raised court. The best-preserved Roman temple is that known as the Maison Carrée at Nîmes in the south of France, a hexastyle pseudo-peripteral temple, of which the elevation is given in fig. 22 and the plan in fig. 23. It was of the Corinthian order, and instead of a stylobate of three steps was raised on a podium 11 ft. high with a flight of steps in front. For further descriptions of both the Greek and Roman temples see ARCHITECTURE.

(R. P. S.)

TEMPLE BAR, an historic site in London, England. In more than one of the main roads converging upon the city of London a bar or chain marked the extra-mural jurisdiction of the Corporation. Temple Bar stood at the junction of the present Strand and Fleet Street, over against the Law Courts. A bar is first mentioned here in 1301, but the name is most familiar in its application to the gateway designed by Sir Christopher Wren, which replaced an older structure on this spot in 1672. This was removed in 1878, and set up in 1888 at the entrance to Theobalds Park near Cheshunt, Hertfordshire. A pedestal surmounted by a dragon or "griffin" marks the old site. When the sovereign is about to enter the city in state, whether by Temple Bar or elsewhere, the Lord Mayor, in accordance with ancient custom, presents the sword of the city to him, and he at once returns it. Formerly the bar or gate was closed against the sovereign until this ceremony was carried out.

TEMRYUK, a seaport of Russia, in northern Caucasia, and in the government of Kuban, on the Sea of Azov, 81 m. W.N.W. of Ekaterinodar. Pop. (1897) 14,476. Here was a Turkish fortress, Abas, till 1774. The place is now a growing seaport for the export of grain, and has many flour-mills.

TENANT (from Lat. *tenere*, to hold), one who holds real property by some form of title from a landlord. For the forms of tenancy, &c., see LANDLORD AND TENANT.

TENANT-RIGHT, in law, a term expressing the right which a tenant has, either by custom or by law, against his landlord for compensation for improvements at the determination of his tenancy. In England it is governed for the most part by the Agricultural Holdings Acts and the Allotments and Small Holdings Acts (see LANDLORD AND TENANT). In Ireland, tenant-right was a custom, prevailing particularly in Ulster, by which the tenant acquired a right not to have his rent raised arbitrarily at the expiration of his term. This resulted in Ulster in considerable fixity of tenure and, in case of a desire on the part of the tenant to sell his farm, made the tenant-right of considerable capital value, amounting often to many years' rent.

TENASSERIM, a division of Lower Burma, bordering on Siam. Area, 36,076 sq. m. Pop. (1901) 1,159,558, including 38,269 Christians, the great majority of whom are Karens. The headquarters of the commissioner are at Moulmein. It is divided into six districts: Toungoo, Salween, Thatôn, Amherst, Tavoy and Mergui. It formed the tract south of Pegu conquered from Burma in 1826, which was for many years known as the Tenasserim province. The southern extremity of the division approaches the insular region of Malaysia, and it is fringed along its entire western coast by a number of islands, forming in the north the Moscos and in the south the Mergui Archipelago. The eastern frontier is formed by a mountain range 5000 ft. high, which acts as a water-parting between the Tenasserim and the Siamese river systems.

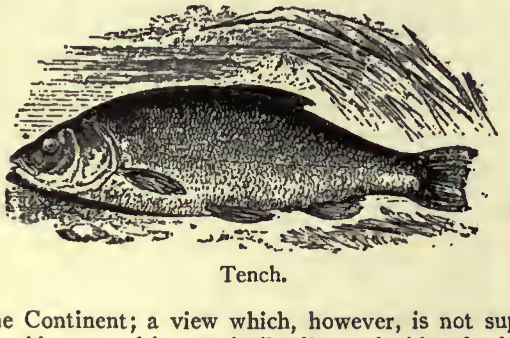
TEN BRINK, BERNHARD EGIDIUS KONRAD (1841–1892), German philologist, of Dutch origin, was born at Amsterdam on the 12th of January 1841, but was sent to school at Düsseldorf, and afterwards studied at Münster, and later under Diez and Delius at Bonn. In 1866 he began to lecture at the Münster Academy on the philology of the English and Romance languages. In 1870 he became professor of modern languages at Marburg, and after the reconstitution of Strassburg University was appointed professor of English there in 1873. In 1874 he began to edit, in conjunction with W. Scherer, E. Martin and E. Schmidt, *Quellen und Forschungen zur Sprache und Kulturgeschichte der germanischen Völker.* He devoted himself for many years to the study of Chaucer. In 1877 he published *Chaucer: Studien zur Geschichte seiner Entwickelung und zur Chronologie seiner Schriften*; in 1884, *Chaucers Sprache und Verskunst.* He also published critical editions of the *Prologue* and the *Compleynte to Pitê.* Ten Brink's work in this direction stimulated a revival of Chaucer study in the United Kingdom as well as in Germany, and to him was indirectly due the foundation of the English Chaucer Society. His *Beowulf-Untersuchungen* (1888) proved a hardly less valuable contribution to the study of Early English literature. His best known work is his *Geschichte der englischen Literatur* (1889–93), (English by H. Kennedy in Bohn's *Standard Library*), which was unfortunately never completed, and broke off just before the Elizabethan period. It was his intense admiration of Shakespeare that first attracted him to the study of English, and five lectures on Shakespeare delivered at Frankfort were published after his death (1893). Ten Brink died at Strassburg on the 29th of January 1892. He was a great teacher as well as an accurate and brilliant writer, and from many countries students flocked to his lecture-room.

TENBURY, a market town in the Bewdley parliamentary division of Worcestershire, England, on the Kidderminster-Wooferton branch of the Great Western railway, 153 m. W.N.W. of London. Pop. (1901) 2080. It is pleasantly situated on the right bank of the Teme, here the boundary with Shropshire. The town has a spa, whose waters are efficacious in rheumatic affections and diseases of the skin. The church of St Mary the Virgin has Norman remains in the tower and chancel. The district produces hops and fruit, and there is trade in cider. The Teme abounds in trout and grayling, and Tenbury is in favour with anglers. At Old Wood, 2 m. S.W. of Tenbury, are St Michael's church and college (1858), founded and partially endowed by the Rev. Sir Frederick Gore Ouseley, in which the ordinary preparatory education of boys is combined with a school for choristers and instruction in ecclesiastical music.

TENBY, a market town, seaside resort, a municipal and contributory parliamentary borough of Pembrokeshire, Wales, finely situated on a long narrow promontory of limestone rock washed on three sides by the sea on the west shore of Carmarthen Bay. Pop. (1901) 4400. Tenby is a station on the Whitland-Pembroke Dock branch of the South Wales system of the Great Western railway. Its chief attractions as a watering-place are its picturesque appearance and surroundings, its extensive antiquarian remains, its mild climate and its two excellent beaches known as the North and South Sands. The ancient town walls survive almost intact on the north and west sides, and retain the fine St George's gateway, locally called the "Five Arches." These walls, which were largely rebuilt by Jasper Tudor, earl of Pembroke, during the Wars of the Roses, were again repaired under Elizabeth during the alarm of the Spanish invasion, as is shown by a contemporary tablet bearing the queen's cipher and the date 1588. The inconsiderable ruins of the castle, presenting a portion of the keep and outer walls, occupy a rocky peninsula to the S.E. of the town known as the Castle Hill, which also contains the Welsh national monument to Albert, prince consort, an immense statue and pedestal of white marble erected in 1865. Upon the Castle Hill is a small museum, containing some antiquities and good collections of the local flora and marine fauna, for which last Tenby has long been celebrated. Opposite the Castle Hill, about 100 yds. distant, but only accessible to foot passengers at low tide, is St Catherine's Rock with a fort constructed in 1865. Facing the Esplanade and South Sands, about $2\frac{1}{2}$ m. from the shore, stretches Caldy Island, 1 m. in length and $\frac{2}{3}$rd m. in breadth, with a population of seventy persons and containing a ruined priory, which was a subsidiary house to St Dogmell's Abbey. To the west, between Caldy Island and Giltar Point on the mainland, lies St Margaret's Rock. The parish church of St Mary, situated at the northern end of Tudor Square, the principal open space in the town, is one of the largest churches in South Wales, and exhibits all varieties of architecture from the 12th to the 16th centuries. Its massive tower, crowned with a spire, is 152 ft. high, and forms a prominent object in all views of the town. The handsome interior is remarkably rich in early tombs and monuments, the most important of them being the elaborate altar-tomb of John and Thomas White (*c.* 1482), members of an opulent family of merchants long seated in Tenby. In the adjoining churchyard are some remains of the Carmelite friary founded by John de Swynemore in 1399. The harbour on the northern beach is protected by an ancient stone pier, and in 1895 an iron pier was erected below the Castle Hill for the convenience of the steamboats which ply between the town and Bristol, Ilfracombe, &c. The trade of Tenby is inconsiderable, but the fisheries, for which the place was noted at an early period and which gave it its Welsh name of Dinbych y Pysgod, are of great value.

The name of Tenby is undoubtedly a corrupted form of Daneby, recalling the Scandinavian origin of the place. The real importance of Tenby dates from the 12th century, when walls, castle and church were erected for the convenience of the Flemish colonists, who were then being planted in Dyfed. On more than one occasion the newly-founded town was captured, sacked and destroyed by marauding bands of Welshmen, notably in 1152; but on each occasion the place was rebuilt and refortified by the earls-palatine of Pembroke, who greatly favoured this important settlement. The first earl of Pembroke to grant a charter of incorporation was William de Valence, 9th earl (*temp.* Henry III.), and these privileges were extended by his successor, Earl Aylmer. Henry IV., by a charter obtained in 1402, vested the government of the town in a mayor and two bailiffs to be elected annually. Elizabeth in 1580 confirmed all previous charters and incorporated the freeholders under the designation of " the mayor, bailiffs and burgesses of the borough of Tenby." During the 15th century and under the Tudors the town grew extremely prosperous, and contained many wealthy mercantile families, of which that of White offers the most striking example. A member of this house, Thomas White, whilst mayor of Tenby, did signal service to the Lancastrian cause in 1471 by harbouring Jasper Tudor, earl of Pembroke, and his nephew Henry Tudor, earl of Richmond (afterwards King Henry VII.), prior to their escape to France. John Leland (*c.* 1540) described Tenby as being " very wealthy by merchandise," and noted its stone pier and well-built walls. The town suffered severely during the Civil Wars, undergoing two sieges, firstly in 1644 when the parliamentarian, Colonel Laugharne, took the place by storm, and secondly in 1648 when it capitulated to Colonel Horton. After the Restoration the importance and wealth of Tenby showed a constant tendency to decline, but towards the close of the 18th century it rose into great popularity as a watering-place, and it has since maintained its reputation as the most picturesque seaside resort of South Wales. Since 1536 Tenby has been a contributory borough to the Pembroke (now Pembroke and Haverfordwest) parliamentary district.

TENCH (*Tinca vulgaris*), a small fish of the Cyprinid family, which is one of the commonest and most widely spread freshwater fishes of Europe. It is generally distributed in all suitable localities throughout England, but is limited to a few lakes and ponds in the south of Scotland and in Ireland. As the tench is of comparatively uncommon occurrence in unenclosed waters, its place among the indigenous fishes of Great Britain has been denied, and it has been supposed to have been introduced



Tench.

from the Continent; a view which, however, is not supported by any evidence, and is practically disposed of by the fact that fossil remains of the fish are found in the Pleistocene deposits of Great Britain. In central Europe it thrives best in enclosed, preserved waters, with a clayey or muddy bottom and with an abundant vegetation; it avoids clear waters with stony ground, and is altogether absent from rapid streams. The tench is distinguished by its very small scales, which are deeply imbedded in a thick skin, whose surface is as slippery as that of an eel. All the fins have a rounded outline; the short dorsal fin is without a spine, but the males possess a very thick and flattened outer ray in the ventral fins. The mouth is rather narrow and provided at each corner with a very small barbel. Tench if kept in suitable waters are extremely prolific, and as they grow within a few years to a weight of 3 or 4 ℔, and are then fit for the table, they may be profitably introduced into ponds which are already stocked with other fishes, such as carp and pike. They live on small animals or soft vegetable substances, which they root up from the bottom. The albino variety especially, which is known as the " golden tench," can be recommended for ornamental waters, as its bright orange colours render it visible for some distance below the surface of the water. This variety, which seems to have been originally bred in Silesia, is not less well-flavoured than the normally coloured tench, and grows to the same size, viz., to 6 and even 8 ℔.

The tench is really an excellent fish for the table, if kept in cool, clear water for a few days, as it is the custom to do in Germany, in order to rid it of the muddy flavour imparted to it by its favourite abode.

TENCIN, CLAUDINE ALEXANDRINE GUÉRIN DE (1681–1749), French courtesan and author, was born at Grenoble. Her father, Antoine Guérin, sieur de Tencin, was president of the parlement of Grenoble. Claudine was brought up at a convent near Grenoble and, at the wish of her parents, took the veil, but broke her vows and succeeded, in 1714, in gaining formal permission from the pope for her secularization. She joined her sister Mme. de Ferriol in Paris, where she soon established a salon, frequented by wits and roués. Among her numerous lovers were the Chevalier Le Camus Destouches, the duc de Richelieu, and according to her biographer many other persons of distinction. The last of her liaisons had a tragic ending. M. de la Fresnaye committed suicide in her house, and Mme. de Tencin spent some time in the Châtelet in consequence, but was soon liberated as the result of a declaration of her innocence by the Grand Conseil. From this time she devoted herself to political intrigue, especially for the preferment of her brother the abbé Tencin, who became archbishop of Embrun and received a cardinal's hat. Eventually she formed a literary salon, which had among its *habitués* Fontenelle, Montesquieu, the abbé de Saint Pierre, Pierre Marivaux, Alexis Piron and others. Hers was the first of the Parisian literary salons to which distinguished foreigners were admitted, and among her English guests were Bolingbroke and Chesterfield. By the good sense with which she conducted what she called her " menagerie," she almost succeeded in effacing the record of her early disgrace. She was a novelist of considerable merit. Her novels have been highly praised for their simplicity and charm, the last qualities the circumstances of the writer's life would lead one to expect in her work. The best of them is *Mémoires du comte de Comminges* (1735), which appeared, as did the other two, under the name of her nephews, MM. d'Argental and Pont de Veyle, the real authorship being carefully concealed. Mme. de Tencin died on the 4th of December 1749.

Her works, with those of Mme. de la Fayette, were edited by Étienne and Jay (Paris, 1825); her novels were reprinted, with introductory matter by Lescure, in 1885; and her correspondence in the *Lettres de Mmes. de Villars, de La Fayette et de Tencin* (Paris, 1805–1832). See P. Masson, *Madame de Tencin* (Paris, 1909).

TENÇIN, PIERRE GUÉRIN DE (1679–1758), French ecclesiastic, archbishop of Embrun and Lyons, and cardinal, was born at Grenoble on the 22nd of August 1679. He owed his quick advance to power to his sister Claudine (see above). He was a strong opponent of the Jansenists, and in 1742 was appointed a minister of state to Louis XV., though he held no portfolio. He died on the 2nd of March 1758.

TENDER. (1) An adjective meaning soft, either physically or figuratively, derived from Fr. *tendre*, Lat. *tener*, soft, allied to *tenuis*, thin, and ultimately to be referred to the root, *tan-*, to stretch out, as in Lat. *tendere*. (2) A legal term meaning an offer for acceptance, particularly an offer in money for the satisfaction of a debt or liability or an offer to pay or deliver according to the terms of a contract; for "legal tender," the currency which can legally be offered and must be accepted in payment, see PAYMENT. The term is also applied specifically to an offer to do a specified piece of work or to supply certain goods for a certain sum or at a certain rate or to purchase goods at a certain rate. Contracts for large or important works or for the supply of large amounts of goods are usually put out to tender in order to secure the lowest price. In this sense the word is from "to tender," to offer, Fr. *tendre*, Lat. *tendere*, to stretch out. (3) A "tender" is also one who "attends" (Lat. *attendere*, to stretch towards, to give heed to), and so is applied particularly to a small vessel which brings supplies, passengers, &c., to a larger vessel, or which is used to take or bring messages from or to her, and similarly to a carriage attached to a locomotive engine on a railway which carries coal or other fuel and water.

TENEBRAE (Lat. for "shadows," "darkness"), the name for an office sung in Roman Catholic churches on the afternoon or evening of Wednesday, Thursday, and Friday of Holy Week. The name is derived, according to Durandus (*Ration.*, lib. vi. cap. 72, n. 2), from the fact that "the church on these days cultivates darkness (*tenebras colit*): firstly because it is in sorrow and grief on account of the Lord's Passion, and because for three days it celebrates his exequies since for three days he was dead; secondly, the office of Tenebrae symbolizes the darkness that fell on the face of the earth while the Sun of justice was hung upon the cross," &c. The falling darkness is symbolized by a peculiar and singularly impressive ceremony (see LIGHTS, CEREMONIAL).

TENEMENT (Med. Lat. *tenementum*, from *tenere*, to hold), in law, a term which, according to Coke, "includes not only all corporate inheritances which are or may be holden, but also all inheritances issuing out of those inheritances, or concerning, or annexed to, or exercisable within the same" (Co. Litt. 20a). In its more general legal sense it is applied to realty, as opposed to personalty. In its popular sense tenement is used as meaning a house or dwelling, and, more particularly in large cities, tenement houses are buildings occupied by several families living independently of one another, but having a common right in the hall, staircases and outhouses. In the heart of great towns the problem of housing is a difficult one, and it is only of recent years that attention has been directed to the unsuitable and insanitary condition of many houses occupied on the tenement system as defined above, but in many cases never built with the conveniences necessary for joint occupation. In most of the large cities in Great Britain and the United States tenement houses are now built on the most modern plans (see HOUSING), and it is to be noted that the municipality of New York has a special Tenement-house Department, under charge of a commissioner, with wide authority to supervise the structure of tenement houses and their occupancy in the interest of health and general welfare.

TENERIFFE [Tenerife], the largest of the Canary Islands; in the Atlantic Ocean, and belonging to Spain. Pop. (1900) 138,008; area, 782 sq. m. Teneriffe lies a little west of the centre of the archipelago, between the islands of Grand Canary and Gomera. It is of irregular shape, 60 m. long, with an extreme breadth of 30 m. A chain of mountains traverses the island in the direction of its greatest length (east to west), and in the middle of the broadest part rises the celebrated peak, locally known as the Pico de Teyde (or Teide), which, with its supports and spurs, occupies nearly two-thirds of the whole island. It has a double top; the highest point, El Piton, is 12,200 ft. above the sea; the other, Chahorra, connected with the first by a short narrow ridge, has a height of 9880 ft. They are both orifices in the same grand dome of trachyte. Neither reaches the line of perpetual snow. There is, however, a natural cavern, 11,050 ft. above the sea, where snow is preserved all the year. Snow remains for about four months on the upper part of the peak.

For more than one-half of its circumference the base of the true peak rises from an elevated but comparatively level tract, called by the Spaniards *El Llano de la Retama* (*retama* being the name of the *Cytisus nubigenus* which abounds there), and by the English the Pumice-Stone Plains. On the south-east, south and south-west there is a high curved ridge overlooking the Pumice-Stone Plains, and presenting a very steep face to the peak. Between the ridge and the sea the slope is more gradual, and there are intervening tablelands. Peaks rise from the ridge, one of which (Guajara) attains the height of 8900 ft. This ridge (the Llano) and the modern volcanic cone resemble in aspect a fortress with circular ramparts and a fosse. The ramparts are about 8 m. in diameter, and tower in some places more than 1500 ft. above the fosse. On the north-west comparatively late eruptions have filled up the fosse. The modern cone is a pile of lava, pumice and ashes, thrown up in an ancient crater which had become greatly enlarged either by a falling in of the upper part of the cone, or by a series of violent explosions. Both El Piton and Chahorra have craters on their summits, from which issue steam and a little sulphurous vapour. The crater on El Piton is partly surrounded by a wall of lava, which has been made white by the action of sulphurous vapours, and every crevice contains small crystals of sulphur. The thermometer rises considerably when thrust into the ground. The crater is about 300 ft. across, with a depth of 70 ft. The crater on Chahorra has a diameter of 4000 ft.; its depth is scarcely 150 ft. The view from the highest point, when no clouds intervene, is very extensive. All the islands of the archipelago are visible, and the horizon is 140 m. distant. Neither the coast of Africa nor the island of Madeira is within the range of vision.

The ascent of the peak is usually made from Orotava, on the northern side of the island. After the cultivated grounds are left, the region of arborescent heaths is crossed. Above this is a belt covered with *codeso* (*Adenocarpus frankenioides*), and this extends to the region of *retama*, the first bushes of which are found at the pass which admits the traveller into the *Llano de la Retama*. The scenery here is in striking contrast with what it has previously been. Instead of a steep and rugged ascent among black basaltic rocks, the traveller enters upon gently sloping ground, covered to a considerable depth with white pumice gravel, amongst which spring bushes of retama. The tender shoots of this shrub serve the wild goats for food, and the flowers yield a rich honey. The entrance to the Llano at a sort of natural gateway (called *Portillo*) between two basaltic hills, is about 7000 ft. above the sea. Between two and three hours are consumed in crossing the Llano to the base of the cone, the lower part of which (*Monton de Trigo*) is ascended to a point 9750 ft. above the sea, called *Estancia de los Ingleses*, where the mules are usually left, and travellers frequently pass the night. Then comes the Malpays, 1000 ft. in altitude, consisting of rough black lava streams broken up into blocks and stones. These cease at the Rambleta, the lip of an older crater over which the lava poured before the sugar-loaf cone of pumice and ashes was thrown up. The pumice is in such quantity that at a distance it has the appearance of snow coating the peak. From twenty to twenty-four hours are consumed in ascending the peak and returning to Orotava.

To the north-west of the grand cone, some thousands of feet below Chahorra, there are many small cones of eruption, showing that the intensity of volcanic action was greatest on this side. Eastward from the ridge bounding the Pumice-Stone Plains extends a chain of mountains to the north-eastern extremity of the island. The highest peaks are Izana (7374 ft.), Perejil (6027), and Cuchillo (5467).

There is no record of eruptions from either crater of the peak. In 1795 a great quantity of lava was poured out from three vents on the eastern side; and in the same year lava streams issued from a crater near Guimar, half-way between Santa Cruz and the peak. In the year 1706 a vent on the north-western side of the peak discharged a copious stream, which flowed down to the sea, and nearly filled up the harbour of Garachico. For three months in 1798 much lava and other volcanic matter were ejected from orifices to the west of Chahorra.

Santa Cruz, the capital of Teneriffe and of the Canaries (pop. 1900, 38,419), and La Laguna (13,074), the former capital, are described in separate articles. A good road connects Santa Cruz and Orotava, a town on the north coast 25 m. W.N.W. It passes through Laguna and Matanza—a place deriving its name from the overthrow of the invading Spaniards by the Guanches in 1494. All travellers speak in terms of warm admiration of the scenery in this part of the island. Date-palms form a striking feature in the landscapes. The town of Orotava (pop. 9192) is 1040 ft. above the sea. The houses are solidly built, but it has a deserted aspect. A stream of water is conducted through every street. The famous dragon-tree, which so many travellers have described, no longer exists. Port Orotava, 3 m. N. of the town, is a clean place, with about 4500 inhabitants. The streets are broad and the houses well built. The roadstead, protected by a fort and some batteries, affords little or no shelter against wind. At Icod de los Vinos, a pretty town of

4000 inhabitants, farther to the west, in a fertile district, is a dragon-tree, the largest now existing in the island. The stem near the ground has a circumference of 38 ft. and its height is upwards of 60 ft. Near the town is an immense cavern, in which many Guanche bones were found. There are several other towns of less importance, principally in the north-west, not far from the coast. The highest inhabited place is Chasna, on a plain more than 4000 ft. above the sea, to the south of the peak. See also CANARY ISLANDS.

TENIERS, the name of a family of Flemish artists who flourished at Antwerp and Brussels during the 17th century.

DAVID TENIERS, the elder (1582–1649), was born at Antwerp. Having received his first training in the painter's art from his brother Juliaen, he studied under Rubens in Antwerp, and subsequently under Elsheimer in Rome; he became a member of the Antwerp gild of painters in 1606. Though his ambition led him at times to try his skill in large religious, historical and mythological compositions, his claim to fame depends chiefly on his landscapes and paintings of peasants carousing, of kermesse scenes and the like, which are marked by a healthy sense of humour, and which are not infrequently confused with the early works of his son David. There is a large painting by the elder Teniers at St Paul's church in Antwerp, representing the "Works of Charity." At the Vienna Gallery are four landscapes painted by Teniers under the influence of Elsheimer, and four small mythological subjects, among them "Vertumnus and Pomona," and "Juno, Jupiter and Io." The National Gallery has a characteristic scene of village life, "Playing at Bowls," a "Conversation" of three men and a woman, and a large "Rocky Landscape." Other examples of his work are to be found at the galleries of St Petersburg, Madrid, Brussels, Munich, Dresden and Berlin ("The Temptation of St Anthony"). Teniers also achieved success as a picture dealer, and is known to have attended the fair of St Germain in Paris in 1635, with a large number of paintings by himself and by his four sons. He died at Antwerp in 1649.

DAVID TENIERS, the younger (1610–1690), the more celebrated son of the last-named, almost ranking in celebrity with Rubens and Van Dyck, was born in Antwerp on the 15th of December 1610. Through his father, he was indirectly influenced by Elsheimer and by Rubens. We can also trace the influence of Adrian Brouwer at the outset of his career. There is no evidence, however, that either Rubens or Brouwer interfered in any way with Teniers's education, and Smith (*Catalogue Raisonné*) may be correct in supposing that the admiration which Brouwer's pictures at one time excited alone suggested to the younger artist his imitation of them. The only trace of personal relations having existed between Teniers and Rubens is the fact that the ward of the latter, Anne Breughel, the daughter of John (Velvet) Breughel, married Teniers in 1637. Admitted as a "master" in the gild of St Luke in 1632, Teniers had even before this made the public acquainted with his works. The Berlin Museum possesses a group of ladies and gentlemen dated 1630. No special signature positively distinguishes these first productions from those of his father, and we do not think it correct to admit with some writers that he first painted religious subjects. Dr Bode, in a remarkable study of Brouwer and his works, expresses the opinion that Teniers's earliest pictures are those found under the signature "Tenier." Tenier is a Flemish version of a thoroughly Walloon name, "Taisnier," which the painter's grandfather, a mercer, brought with him when he came from Ath in 1558; and Dr Bode's supposition is greatly strengthened by the circumstance that not only David the elder but his brother Abraham and his four sons were all inscribed as "Tenier" in the ledgers of the Antwerp gild of St Luke. Some really first-rate works—the "Prodigal Son" and a group of "Topers" in the Munich Gallery, as well as a party of gentlemen and ladies at dinner, termed the "Five Senses," in the Brussels Museum—with the above signature are remarkable instances of the perfection attained by the artist when he may be supposed to have been scarcely twenty. His touch is of the rarest delicacy, his colour at once gay and harmonious. Waagen and Smith agree that the works painted from 1645 to 1650 testify most highly to the master's abilities; there is no doubt that a considerable number of earlier productions would have been sufficient to immortalize his name. He was little over thirty when the Antwerp gild of St George enabled him to paint the marvellous picture which ultimately found its way to the Hermitage Gallery in St Petersburg—the "Meeting of the Civic Guards." Correct to the minutest detail, yet striking in effect, the scene, under the rays of glorious sunshine, displays an astonishing amount of acquired knowledge and natural good taste. This painting leads us to mention another work of the same year (1643), now in the National Gallery, London, "The Village Fête" (or "*La fête aux chaudrons*") (No. 952), an equally beautiful repetition of which, dated 1646, belongs to the duke of Bedford. Truth in physiognomy, distribution of groups, the beautiful effect of light and shade, command our warmest admiration. A work like this, says Waagen, stamps its author as the greatest among painters of his class. Frankness in expression and freedom in attitude guided his preference in the choice of a model, but we may suppose him occasionally to have exaggerated both. He seems anxious to have it known that, far from indulging in the coarse amusements of the boors he is fond of painting, he himself lives in good style, looks like a gentleman, and behaves as such. He never seems tired of showing the turrets of his château of Perck, and in the midst of rustic merry-makings we often see his family and himself received cap in hand by the joyous peasants. We may also observe that he has a certain number of favourite models, the constant recurrence of whom is a special feature of his works. We have even met them in a series of life-size portrait-like figures in the Doria Pamphili Gallery in Rome.[1]

Teniers was chosen by the common council of Antwerp to preside over the gild of painters in 1644. The archduke Leopold William, who had assumed the government of the Spanish Netherlands, being a great lover of art, employed Teniers not only as a painter but as keeper of the collection of pictures he was then forming. With the rank and title of "ayuda de camara," Teniers took up his abode in Brussels shortly after 1647. Immense sums were spent in the acquisition of paintings for the archduke. A number of valuable works of the Italian masters, now in the Vienna Museum, came from Leopold's gallery after having belonged to Charles I. and the duke of Buckingham. De Bie (1661) states that Teniers was some time in London, collecting pictures for the duke of Fuensaldaña, then acting as Leopold's lieutenant in the Netherlands. Paintings in Madrid, Munich, Vienna and Brussels have enabled art critics to form an opinion of what the imperial residence was at the time of Leopold, who is represented as conducted by Teniers and admiring some recent acquisition. No picture in the gallery is omitted, every one being inscribed with a number and the name of its author, so that the *ensemble* of these paintings might serve as an illustrated inventory of the collection.[2] Still more interesting is a canvas, now in the Munich Gallery, where we see Teniers at work in a room of the palace, with an old peasant as a model and several gentlemen looking on. When Leopold returned to Vienna, Teniers's task ceased; in fact, the pictures also travelled to Austria, and a Flemish priest, himself a first-rate flower painter, Van der Baren, became keeper of the archducal gallery. Teniers nevertheless remained in high favour with the new governor-general, Don Juan, a natural son of Philip IV. The prince was his pupil, and de Bie tells us he painted the likeness of the painter's son. Honoured as one of the greatest painters in Europe, Teniers seems to have made himself extremely miserable through his aristocratic

[1] Under the name of Weenix.

[2] It was not until recent years that the MS. inventory of this collection was discovered among the papers of Prince Schwartzenberg in Vienna. It was published in 1883 by Adolf Berger. In 1658 Teniers published 243 etchings after the best Italian works of Leopold William's collection, which, with the portraits of the archduke and Teniers, were brought together as a volume in 1660, under the title *El Teatro de Pinturas*.

leanings. Shortly after the death of his wife in 1656 he married Isabella de Fren, daughter of the secretary of the council of Brabant, and strove his utmost to prove his right to armorial bearings. In a petition to the king he reminded him that the honour of knighthood had been bestowed upon Rubens and Van Dyck. The king at last declared his readiness to grant the request, but on the express condition that Teniers should give up selling his pictures. The condition was not complied with; but it may perhaps account for the master's activity in favour of the foundation in Antwerp of an academy of fine arts to which only painters and sculptors should be admitted, whereas the venerable gild of St Luke made no difference between art and handicraft: carvers, gilders, bookbinders, stood on an even footing with painters and sculptors: the separation was not obtained till 1773. There were great rejoicings in Antwerp when, on the 26th of January 1663, Teniers came from Brussels with the royal charter of the academy, the existence of which was due entirely to his personal initiative.

Teniers died in Brussels on the 25th of April 1690. The date is often wrongly given as 1694 or 1695. A picture in the Munich Gallery (No. 906), dated 1680, represents him as an alchemist, oppressed with a burden of age beyond his years. From this date we hear more of his doings as a picture-dealer than as a painter, which most probably gave birth to the legend of his having given himself out as deceased in order to get higher prices for his works. David, his eldest son, a painter of talent and reputation, died in 1685. One of this third Teniers's pictures—"St Dominic Kneeling before the Blessed Virgin," dated 1666—is still to be found in the church at Perck. As well as his father, he contributed many patterns to the celebrated Brussels tapestry looms.

Smith's *Catalogue Raisonné* gives descriptions of over 900 paintings accepted as original productions of Teniers. Few artists ever worked with greater ease, and some of his smaller pictures—landscapes with figures—have been termed "afternoons," not from their subjects, but from the time spent in producing them. The museums in Madrid, St Petersburg, Vienna, Munich, Dresden, Paris, London and Brussels have more than 200 pictures by Teniers. In the United Kingdom 150 may be found in private hands, and many other examples are to be met with in private collections throughout Europe. Although the spirit of many of these works is as a whole marvellous, their conscientiousness must be regarded as questionable. Especially in the later productions, from 1654 onwards we often detect a lack of earnestness and of the calm and concentrated study of nature which alone prevent expression from degenerating into grimace in situations like those generally depicted by Teniers. His education, and still more his real and assumed position in society, to a great degree account for this. Brouwer knew more of taverns; Ostade was more thoroughly at home in cottages and humble dwellings; Teniers, throughout, triumphs in broad daylight, and, though many of his interiors may be justly termed masterpieces, they seldom equal his open-air scenes, where he has, without constraint, given full play to the bright resources of his luminous palette. In this respect he often suggests comparisons with Watteau. But his subjects taken from the Gospels or sacred legend are absurd. An admirable picture in the Louvre shows "Peter Denying his Master" next to a table where soldiers are smoking and having a game at cards. A similar example is the "Deliverance of St Peter from Prison" of which two versions, curiously altered, are in the Dresden Gallery and the Wallace Collection. He likes going back to subjects illustrated two centuries before by Jerome Bosch—the "Temptation of St Anthony," the "Rich Man in Hell," incantations and witches—for the simple purpose of assembling the most comic apparitions. His villagers drink, play bowls, dance and sing; they seldom quarrel or fight, and, if they do, seem to be shamming. This much may be said of Teniers, that no painter shows a more enviable ability to render a conception to his own and other people's satisfaction. His works have a technical freshness, a straightforwardness in means and intent, which make the study of them most delightful; as Sir Joshua Reynolds says, they are worthy of the closest attention of any painter who desires to excel in the mechanical knowledge of his art.

As an etcher Teniers compares very unfavourably with Ostade, Cornelis, Bega and Dusart. More than 500 plates were made from his pictures; and, if it be true that Louis XIV. judged his "baboons" (*magots*) unworthy of a place in the royal collections, they found admirable engravers in France—Le Bas and his scholars—and passionate admirers. The duke of Bedford's admirable specimen was sold for 18,030 livres (£1860) in 1768. The "Prodigal Son," now in the Louvre, fetched 30,000 livres (£3095) in 1776. Smith's highest estimates have long since been greatly exceeded. The "Archers" in St Petersburg he gives as worth £2000. The Belgian government gave £5000 in 1867 for the "Village Pastoral" of 1652, which is now in the Brussels Museum; and a picture of the "Prodigal Son," scarcely 16 by 28 inches, fetched £5280 in 1876.

Although van Tilborgh, who was a scholar of Teniers in Brussels, followed his style with some success, and later painters often excelled in figure-painting on a small scale, Teniers cannot be said to have formed a school. Properly speaking, he is the last representative of the great Flemish traditions of the 17th century.

TENISON, THOMAS (1636–1715), English archbishop, was born at Cottenham, Cambridgeshire, on the 29th of September 1636. He was educated at the free school, Norwich, whence he entered Corpus Christi College, Cambridge, as a scholar on Archbishop Parker's foundation. He graduated in 1657, and was chosen fellow in 1659. For a short time he studied medicine, but in 1659 was privately ordained. As vicar of St Andrew-the-Great, Cambridge, he was conspicuous for his devoted attention to the sufferers from the plague. In 1667 he was presented to the living of Holywell-cum-Needingworth, Huntingdonshire, by the earl of Manchester, to whose son he had been tutor, and in 1670 to that of St Peter's Mancroft, Norwich. In 1680 he received the degree of D.D., and was presented by Charles II. to the important cure of St Martin's-in-the-Fields. Tenison, according to Gilbert Burnet, "endowed schools, set up a public library, and kept many curates to assist him in his indefatigable labours." Being a strenuous opponent of the Church of Rome, and "Whitehall lying within that parish, he stood as in the front of the battle all King James's reign." In 1678, in a *Discourse of Idolatry*, he had endeavoured to fasten the practices of heathenish idolatry on the Church of Rome, and in a sermon which he published in 1681 on *Discretion in Giving Alms* was attacked by Andrew Pulton, head of the Jesuits in the Savoy. Tenison's reputation as an enemy of Romanism led the duke of Monmouth to send for him before his execution in 1685, when Bishops Ken and Turner refused to administer the Eucharist; but, although Tenison spoke to him in "a softer and less peremptory manner" than the two bishops, he was, like them, not satisfied with the sufficiency of Monmouth's penitence. Under William III., Tenison was in 1689 named a member of the ecclesiastical commission appointed to prepare matters towards a reconciliation of the Dissenters, the revision of the liturgy being specially entrusted to him. A sermon which he preached on the commission was published the same year. He preached a funeral sermon on Nell Gwyn (d. 1687) in which he represented her as truly penitent—a charitable judgment which did not meet with universal approval. The general liberality of Tenison's religious views commended him to the royal favour, and, after being made bishop of Lincoln in 1691, he was promoted to the primacy in December 1694. He attended Queen Mary during her last illness and preached her funeral sermon in Westminster Abbey. When William in 1695 went to take command of the army in the Netherlands, Tenison was appointed one of the seven lords justices to whom his authority was delegated. Along with Burnet he attended the king on his death-bed. He crowned Queen Anne, but during her reign was not in much favour at court. He was a commissioner for the Union with Scotland in 1706. A strong supporter of the Hanoverian succession, he was one of the three officers of state to whom on the death of Anne was entrusted the duty of appointing a regent till the arrival of George I., whom he crowned on the 31st of October 1714. Tenison died at London on the 14th of December 1715.

Besides the sermons and tracts above mentioned, and various others on the "Popish" controversy, Tenison was the author of *The Creed of Mr Hobbes Examined* (1670) and *Baconia, or Certain*

Genuine Remains of Lord Bacon (1679). He was one of the founders of the Society for the Propagation of the Gospel.

The *Memoirs of the Life and Times of the Most Rev. Father in God, Dr Thomas Tenison, late Archbishop of Canterbury*, appeared without date not long after his death. See also Gilbert Burnet's *History of his own Time* and Macaulay's *History of England.*

TEN KATE, JAN JACOB LODEWIJK (1819–1889), Dutch divine, prose writer and poet, was born at The Hague on the 23rd of December 1819. He started in life as a lawyer's clerk. It was his friend, Dr Heldring, pastor at Hemmen, in Gelderland, who, discovering in Ten Kate the germs of poetical genius, enabled him to study theology at the university of Utrecht (1838–43). Having completed his studies, Ten Kate became pastor at Middelburg, Amsterdam, and other places, meanwhile developing well-nigh ceaseless activity, both in prose and lyric poetry. Among his prose works may be mentioned the travel papers (Rhine, 1861; Italy, 1857–62), *Christelijke Overdenkingen* ("Thoughts of a Christian," 1849–52), and other religious studies. His early poetry was in the main original. The best known of his poems were—*Ahasverus op de Grimsel* ("Ahasuerus on the Grimsel," 1840); *Zangen des Tijds* ("Songs of the Times," 1841); *Legenden en Mengelpoëzie* ("Legends and Detached Poems," 1846); *In den Bloemhof* ("In the Flower Garden," 1851); *De Schepping* ("The Creation," 1866); *De Planeten* ("The Planets," 1869); *De Jaargetijden* ("The Seasons," 1871); *De Psalmen* ("The Psalms," 1874); *De Vrouw in het Nederlandsch Lied* ("Woman in Dutch Song," 1882); *Palmtakken en Dichtbloemen* ("Palm-branches and Flowers of Poesy," 1884). Ten Kate reached the pinnacle of his poetic fame in *The Creation, The Planets*, and *The Seasons.* These poems certainly show a masterly grasp of his mother tongue and a wonderful facility of expression, coupled with graceful vigour and fertile fancy. These qualities he also plentifully displayed in the innumerable translations he made of many of the masterpieces of foreign poetry in nearly every European language. He had not only an extraordinary aptitude for learning alien idioms, but also the gift of translating foreign lyrics into clear, fluent and beautiful Dutch verse. Ten Kate's versatility in this respect has never been equalled; it extended from Tasso and Andersen to Dante, Schiller, Victor Hugo, Milton, Tennyson and Longfellow. Ten Kate died at Amsterdam on the 24th of December 1889.

His complete *Poetic Works* were published after his death in 12 volumes (Leiden, 1891).

TENNANT, CHARLES (1768–1838), Scottish industrial chemist, was born at Ochiltree, Ayrshire, on the 3rd of May 1768. He started in business as a bleacher at Darnley, and in 1798 took out a patent for a bleach liquor formed by passing chlorine into a mixture of lime and water. This product had the advantage, as compared with the Eau de Javelles, then generally used, that a cheaper base, lime, was substituted for potash in its preparation; but when he attempted to protect his rights against infringement his patent was held invalid on the double ground that the specification was incomplete and that the invention had been anticipated at some bleach-works near Nottingham. In 1799 he patented a more convenient material in bleaching powder or "chloride of lime," formed by the action of chlorine on slaked lime, and for its manufacture founded at Glasgow in 1800 the well-known St Rollox chemical works, now merged in the United Alkali Company. He died at Glasgow on the 1st of October 1838.

His grandson the iron-master, Sir Charles Tennant (1823–1906), was M.P. for Glasgow from 1878 to 1880 and for Peebles and Selkirk from 1880 to 1886; he was created a baronet in 1885.

TENNANT, SMITHSON (1761–1815), English chemist, was born at Selby, Yorkshire, on the 30th of November 1761. He began to study medicine at Edinburgh in 1781, but in a few months moved to Cambridge, where he devoted himself to botany and chemistry. He graduated M.D. at Cambridge in 1790, and about the same time purchased an estate near Cheddar, where he carried out agricultural experiments. He was appointed professor of chemistry at Cambridge in 1813, but lived to deliver only one course of lectures, being killed near Boulogne on the 22nd of February 1815 by the fall of a bridge over which he was riding. He was a man of more promise than performance, and his chief achievement was the discovery of the elements iridium and osmium, which he found in the residues from the solution of platinum ores (1804). He also contributed to the proof of the identity of diamond and charcoal.

TENNANT, WILLIAM (1784–1848), Scottish scholar and poet, was born on the 15th of May 1784 at Anstruther Easter, Fifeshire. He was lame from childhood. His father sent him to the university of St Andrews, where he remained for two years, and on his return he became clerk to one of his brothers, a corn factor. In his leisure time he mastered Hebrew as well as German and Italian. His study of Italian verse bore fruit in the mock-heroic poem of *Anster Fair* (1812), which gave an amusing account of the marriage of "Maggie Lauder," the heroine of the popular Scottish ballad. It was written in the *ottava rima* adopted a few years later by "the ingenious brothers Whistlecraft" (John Hookham Frere), and turned to such brilliant account by Byron in *Don Juan.* The poem, unhackneyed in form, full of fantastic classical allusions applied to the simple story, and brimming over with humour, had an immediate success. Tennant's brother, meanwhile, had failed in business, and the poet became in 1812 schoolmaster of the parish of Dunino, near St Andrews. From this he was promoted (1816) to the school of Lasswade, near Edinburgh; from that (1819) to a mastership in Dollar academy; from that (1834), by Lord Jeffrey, to the professorship of oriental languages in St Andrews. *The Thane of Fife* (1822), shows the same humorous imagination as *Anster Fair*, but the subject was more remote from general interest, and the poem fell flat. He also wrote a poem in the Scottish dialect, *Papistry Stormed* (1827); two historical dramas, *Cardinal Beaton* (1823) and *John Baliol* (1825); and a series of Hebrew Dramas (1845), founded on incidents in Bible history. He died at Devon Grove, on the 14th of February 1848.

A Memoir of Tennant by M. F. Connolly was published in 1861.

TENNEMANN, WILHELM GOTTLIEB (1761–1819), German historian of philosophy, was born at Erfurt. Educated at his native town, he became lecturer on the history of philosophy at Jena in 1788. Ten years later he became professor at the same university, where he remained till 1804. His great work is an eleven-volume history of philosophy, which he began at Jena and finished at Marburg, where he was professor of philosophy from 1804 till his death. He was one of the numerous German philosophers who accepted the Kantian theory as a revelation.

In 1812 he published a shorter history of philosophy, which was translated into English in 1852 under the title *Manual of the History of Philosophy.*

TENNENT, SIR JAMES EMERSON, Bart. (1804–1869), English politician and traveller, the third son of William Emerson, a merchant of Belfast, was born there on the 7th of April 1804. He was educated at Trinity College, Dublin, of which he afterwards became LL.D. He took up the cause of Greek independence, and travelled in Greece, publishing a *Picture of Greece* (1826), *Letters from the Aegean* (1829), and a *History of Modern Greece* (1830); and he was called to the English bar at Lincoln's Inn in 1831. In this year he married the daughter and co-heiress (with her cousin, Robert James Tennent, M.P. for Belfast, 1848–52) of William Tennent, a wealthy merchant at Belfast, who died of cholera in 1832, and he adopted by royal licence the name of his wife in addition to his own. He entered parliament in 1832 as member for Belfast. In 1841 he became secretary to the India Board, and in 1845 he was knighted and appointed colonial secretary of Ceylon, where he remained till 1850. The result of his residence there appeared in *Christianity in Ceylon* (1850) and *Ceylon, Physical, Historical and Topographical* (2 vols., 1859). On his return, he became member for Lisburn, and under Lord Derby was secretary to the Poor Law Board in 1852. From 1852 till 1867 he was permanent secretary to the Board of Trade, and on his retirement he received a baronetcy from Lord Palmerston. In his early years his political views had a Radical tinge, and, although he subsequently joined the Tories, his Conservatism was of a mild type. He withdrew from the Whigs along with Lord Stanley and Sir James Graham, and afterwards adhered to Peel. He died in London on the 6th of March 1869. His family consisted of two daughters and a son, Sir William Emerson Tennent, 2nd baronet (1835–1876), who was an official in the Board of Trade, and at whose death the baronetcy became extinct.

Besides the books above mentioned, Emerson Tennent wrote *Belgium in 1840* (1841), and *Wine; its Duties and Taxation* (1855), and was a contributor to magazines and a frequent correspondent of *Notes and Queries*. (H. Ch.)

TENNESSEE, a South Central state of the United States of North America, lying between latitude 35° and latitude 36° 40′ N. and between longitude 81° 37′ and longitude 90° 28′ W. It is bounded on the N. by Kentucky and Virginia along a line which, because of erroneous surveys, varies considerably, east of the Tennessee river, from the intended boundary—the line of latitude 36° 30′ N.—the variations all being measured to the north of that parallel; on the E. by North Carolina along the line of the crest of the culminating ridge of the Unaka Mountains till within 26 m. of the Georgia frontier, where it turns due south, giving to Tennessee a triangular piece of territory which should have belonged to North Carolina; on the S. by Georgia, Alabama and Mississippi along the 35th parallel of N. lat.; on the W. by the Mississippi river which separates it from Arkansas and Missouri. The extreme length of the state from E. to W. is 432 m., and the extreme breadth is 109 m. its area being 42,022 sq. m., of which 335 sq. m. is water surface.

Physical Features.—Tennessee is traversed in the east by the Unaka Ridges of the Older Appalachian Mountains and by the Great Appalachian Valley; in the middle by the Cumberland Plateau, the Highland Rim Plateau, and the Nashville Basin of the Appalachian Plateau; and in the west by the Gulf Coastal Plains and a narrow strip of the Mississippi Flood Plain. From a maximum elevation of 6636 ft. at Mount Guyot on the North Carolina border, in Sevier county, the surface descends to 117 ft. or less on the Mississippi Flood Plain in the S.W. corner of the state. The general slope, however, is west by north. About 1700 sq. m. are at least 2000 ft. above the sea, but 28,200 sq. m. are less than 1000 ft. above the sea, and the mean elevation of the state is approximately 900 ft. The Unaka Mountains, which occupy a belt 8 to 10 m. wide along its E. border, are a series of somewhat irregular ridges developed on complexly folded and faulted crystalline rocks. Sixteen peaks exceed 6000 ft. in height. They are Mount Guyot (6636 ft.), Clingman Dome (6619 ft.), Mount Le Conte (6612 ft.), Mount Curtis (6568 ft.), Mount Safford (6535 ft.), Mount Love (6443 ft.), Mount Henry (6373 ft.), Roan Mountain (6313 ft.), Luftee Knob (6232 ft.), Peck Peak (6232 ft.), Raven Knob (6230 ft.), Mount Collins (6188 ft.), Tricorner Knob (6188 ft.), Thermometer Knob (6157 ft.), Oconee Mountain (6135 ft.), and Master Knob (6013 ft.). That part of the Great Appalachian Valley which traverses Tennessee is commonly known as the Valley of East Tennessee. It consists of parallel ridges and valleys developed by erosion on folded sandstones, shales and limestones, the valley quality predominating because the weak limestones were of great thickness. The valley areas vary in height from 600 ft. in the south-west to 1000 ft. in the north-east. In the north-east the ridges are more numerous and higher than in the south-west, where White Oak Ridge and Taylor's Mountain are among the highest, although Missionary and Chickamauga Ridges are better known, because of their association with battles of the Civil War. Along the north-west border of the valley a steep escarpment, known as the Cumberland Scarp, rises to the Cumberland Plateau. This plateau has a mean elevation of about 2000 ft., is only slightly rolling, and slopes gently toward the north-west. The W. edge of the plateau is much broken by deep indentations of stream valleys, and drops suddenly downward about 1000 ft. to the Highland Rim Plateau, so named from the scarp formed by its western rim about the Nashville and (farther north) Louisville basins. It is generally level except where it is cut by river valleys. The Nashville Basin, with a more rolling surface, lies for the most part 400 to 600 ft. below the Rim; a few hills or ridges, however, rise to the level of the Rim. The Basin is elliptical in form, extending nearly across the state from N.E. to S.W., with an extreme width of about 60 m.; near its centre is the city of Murfreesboro, and Nashville lies in the north-west. Westward from the Lower Tennessee river the surface of the East Gulf Coastal Plain rises rapidly to the summit of a broken cuesta or ridge and then descends gently and terminates abruptly in a bluff overlooking the Mississippi Flood Plain. The E. slope, about one-fourth the length of the W. slope, is steep and rocky, and the W. slope is broken by the valleys of numerous streams. The bluff, 150 to 200 ft. in height, traverses the state in a rather straight course and between it and the meandering Mississippi, except at a few points where the latter touches it, lie low bottom lands varying in width according to the bends of the river and containing numerous swamps and ponds. In the northern portion, principally in Lake county, is Reelfoot Lake, which occupies a depression formed during an earthquake in 1811. It is 18 m. long, has a maximum width of 3 m., and is the only large lake in the state.

The whole of the Appalachian Province of Tennessee and the southern portion of the Cumberland Plateau, the Highland Rim, and the Lowland Basin are drained southward and westward by the Tennessee river and its tributaries. The valley of the Lower Tennessee is drained northward by the same river. The northern portion of the Cumberland Plateau, Highland Rim, and Lowland Basin are drained northward and westward by the Cumberland river and its tributaries. The western slope of the East Gulf Plains is drained directly into the Mississippi by several small streams.

Fauna.—A few black bears inhabit the Unaka Mountain region. Deer are quite numerous in the forests of the east half of the state. The wolf, fox, lynx ("wildcat"), otter, mink and beaver have become rare. Squirrels, rabbits, wood-chucks, skunks, muskrats and opossums are common. Among game-birds there are a few wild turkeys, wild geese and bob-white (locally "partridge"), and greater numbers of grouse and various ducks; among song-birds the robin, bluebird and mocking-bird are common; and there are also woodpeckers, whippoorwills, blackbirds, hawks, owls, crows and buzzards. There are a few speckled trout in the mountain streams, but the commoner fish are bass, perch, catfish, crappies, pike, drum buffalo, carp, suckers and eels. Rattlesnakes and moccasins, or cottonmouths, both venomous, are occasionally seen.

Flora.—Originally the state was well covered with forests, and about one-half of it is still woodland containing a large variety of trees. On the mountains the trees are chiefly pines, firs, spruce and hemlock. In the swamps of the western part of the state, especially on the Mississippi Flood Plain, the cypress is dominant. In the Lowland Basin small groves of what was once an extensive forest of red cedar remain. Poplar and larch are much more abundant in the western than in the eastern half of the state, and pine is much more abundant in the eastern than in the western half. But in most parts of the state there are mixed forests of white oak, red oak, ash, red gum, black gum, maple, hickory, chestnut, sycamore, magnolia, tulip tree, cherry, pecan, walnut, elm, beech, locust and persimmon. Birch, mulberry, linden, willow, bass-wood, dogwood, the sorrel tree, pawpaw and wild plum are common. There are a few varieties of the rare shittimwood tree (*Bumelia lanuginosa*). Among indigenous shrubs and vines are the hazel, blackberry, gooseberry, whortleberry, huckleberry, grape and cranberry. Blue grass is indigenous in the Lowland Basin. Of numerous medicinal herbs ginseng is the most important.

Climate.—Tennessee is noted for its delightful climate. The mean summer temperature ranges according to elevation from 62° F. on the Unaka Mountains to 72° on the Cumberland Plateau, to 75° in the Valley of East Tennessee and on the Highland Rim, to 77° in the Lowland Basin, and to about 78° on the East Gulf Plains. But the mean winter temperature for each of these divisions varies little from 38°, and the mean annual temperature ranges only from 57° in East Tennessee to 58° in Middle Tennessee and to 60° in West Tennessee. The altitude being the same, the mean annual temperature on the south border of the state is about 2° higher than that on the north border. Usually the highest temperatures of the year are in July and the lowest in January. In some regions there is no record of a temperature as high as 100°; in others there is none as low as −10°; and the average absolute range is about 90°. However, during a period of fifty-four years (1854–1908) the records show a range of extremes from −30° at Erasmus, Cumberland county, in February 1899, to 107° at several places in July 1901. Rarely there are killing frosts, especially in the southern and western parts of the state from the third week in April to the middle of October. An average annual precipitation of about 50 in. is quite equally distributed over the state and a little more than one-half of it is well distributed through the spring and summer months. The average annual snowfall is about 8 in., and the snowfalls are usually light and melt within a few days. The average number of clear, fair, or only partly cloudy days during a year in Tennessee is 260. The warm, moisture-bearing winds blow low from the south or south-west with a free sweep across the state in a direction nearly parallel with the trend of the mountains. Above these are upper currents from the north or north-west. The commingling of the two currents gives rise frequently to westerly and occasionally to easterly winds. The average velocity of the winds is comparatively low and violent storms are rare.

Soil.—The Lowland Basin, the less elevated parts of the Valley of East Tennessee, and parts of the outer portion of the Highland Rim have a fertile limestone soil. The deep deposit of silt on the Mississippi Flood Plain is even more fertile. There are narrow strips of rich alluvium along many other rivers. The soils on the mountains, on the ridges of the Valley of East Tennessee, and on the E. slope of the East Gulf Plains vary greatly according to the rocks from which they are derived. In the Cumberland Plateau, in the inner portion of the Highland Rim, and in the W. slope of the East Gulf Plains there is for the most part a light sandy soil, much of it too poor for cultivation.

Agriculture.—The total area of farms in the state in 1900 was 20,342,058 acres, of which about one-half was classed as "improved." The average size was 90·6 acres, and the average number of acres of improved land per farm was 45·6. Of the total farm acreage 68·8 per cent. was held or operated by owners or part owners, 9·4 per cent. by cash tenants, 17·4 per cent. by share tenants, and the remainder under miscellaneous tenure. Some 15·1 per cent. of all the farms were operated by coloured farmers, who in 1899 produced 22·2 per cent. of the agricultural products of the state, not fed to live stock. The total value of farms, including buildings, was $265,150,750 (the value of buildings being 23·8 per cent. of the total); in addition implements and machinery valued at $15,232,670 were employed. The principal products and their values in 1909 were: wheat, 8,320,000 bushels ($9,568,000); Indian corn, 78,650,000 bushels ($55,055,000); oats, 4,000,000 bushels ($2,120,000); cotton, 240,000 bales; tobacco, 53,290,000 lb, ($4,156,620). The average yield per acre in 1909 was, of wheat 10·4 bushels, of Indian corn 22 bushels, of cotton (1908) 218 lb, of tobacco 730 lb. Cotton is not raised to any extent except in the rich alluvial land of the Mississippi Valley. Tennessee ranked fifth among the tobacco-growing states in 1899 and fourth in 1909. Considerable areas in the central part of the state are admirably adapted for grazing and the raising of fine horses and cattle. The value of live stock on farms and ranges on the 1st of January 1910 was as follows: horses, $36,288,000; mules, $35,670,000; milch cows, $8,828,000; other cattle, $7,797,000; swine, $8,216,000.

Mining.—Previous to the close of the Civil War (1865) mining had been carried on upon a comparatively small scale, but immediately thereafter attention was attracted to the extensive and valuable deposits of coal and iron ore, and their development was begun on a large scale. The minerals of most commercial importance are coal, iron ores, copper ores, marble and phosphate rock.

About 5000 sq. m., or almost one-eighth of the area of the state, is underlaid by the coal measures, which occupy a belt in the Cumberland Plateau from 50 to 70 m. wide extending entirely across the easterly part of the state in a north-easterly, south-westerly direction. The coal is of the soft or "bituminous" kind, generally of excellent quality, and much of it suitable for conversion into gas and coke, of which latter 468,092 long tons were produced in 1905. The mining of coal in the state has developed rapidly in connexion with the notable expansion of the iron and steel industries of the South. In 1908 the product was 6,199,171 tons, valued at $7,118,499.

Iron ore is found and has been mined in many places in the state. The deposits of most commercial importance are the limonites and brown hematites found west of the Cumberland Plateau, and the fossiliferous red hematite which crops out along the eastern base of that plateau. In the early history of Tennessee iron of superior quality was produced, in small charcoal furnaces, from the brown hematites of the central part of the state. A little later, considerable quantities of this iron were shipped and marketed at Pittsburg. After the close of the Civil War (1865) the iron resources of the state attracted renewed attention, particularly the brown and red hematites, and large and modern furnaces were erected in the Chattanooga district to reduce these ores. The output of iron ore was 874,542 tons (valued at $1,123,527) in 1902, when Tennessee ranked fifth among the iron ore producing states. Owing to the industrial depression following 1907 the output was only 635,343 tons, valued at $876,007, in 1908.

The only copper mines of industrial importance are the Ducktown mines in the extreme south-eastern corner of the state. Copper has been mined here since 1847, and notwithstanding the difficulties of transportation through a rough mountain region, mines were rapidly developed, and in 1855 over 14,000 tons of ore, worth more than a million dollars, were marketed. These mines were the principal source of the supply of copper for the Confederate States during the Civil War. The opening, in 1869, of a railway passing directly through the mining territory, made it possible to work the mines more profitably, and operations were developed on a large scale. In 1908, 618,806 short tons of ore were mined, producing, from the smelters on the ground, 19,710,103 lb of metallic copper. The ore is a sulphide, and in 1898 an extensive plant was erected to manufacture sulphuric acid as a by-product.

In 1892–1893 large deposits of phosphate rock of high quality were discovered in the central-southern part of the state about 60 m. south-west of Nashville, and the rapid development of quarries was begun. The output increased from 19,188 tons in 1894 to 638,612 tons (valued at $3,047,836) in 1907, when Tennessee ranked second among the states of the Union in the production of phosphate-rock. The introduction of this new supply had a marked effect on the fertilizer business of the country.

Inexhaustible deposits of marble are found in Eastern Tennessee in an area about 100 m. long by 20 m. wide, the centre of which is Knox county, the deposits extending southward into Georgia. These marbles are of a distinctive character, being usually mottled in bright shades of red, pink, chocolate and grey. They are employed principally for interior decoration, and were thus largely used in the capitol at Nashville and in the National Capitol at Washington. Systematic quarrying of these marbles was begun as early as 1838, and the output of the quarries has constantly increased since the Civil War.

In 1908 Tennessee produced 179 ozs. of fine gold and 57,696 ozs. of fine silver, a part of each coming, as a by-product, from the copper refineries. Zinc ore is mined on a small scale in the eastern part of the state, the product in 1908 being 341 short tons of metallic zinc valued at $32,054. Among the other minerals found and mined to a limited extent are lead, manganese, barytes, fluorspar, slate, granite and petroleum. The total value of all minerals was $19,277,031 in 1908.

Manufactures.—To an unusual degree the natural resources of the state supply the raw material for its manufactures. The ownership of industrial establishments is largely in the hands of individuals, firms, and comparatively small corporations, rather than of large combinations, the average capital per establishment in 1905 being about $32,000. The amount of capital invested in manufacturing in 1880 was $20,092,845, and the value of the products was $37,074,886. In 1905 capitalization (under the factory system) had increased to $102,439,481, and value of products to $137,960,476. This rapid industrial growth has been due in no small degree to the great natural resources of the state and its excellent transportation facilities. Judged by the value of products, regardless of cost of materials used, the flour and grist mill industry ranked first in 1905 ($25,350,758). Second in importance was the timber and lumber industry and lumber products ($21,580,120.)

The state has always held an important place in the iron and steel industry. The capital invested in blast furnaces in 1905 was $5,939,783, they employed 1486 persons, and the value of their products was $3,428,049. The foundries and machine shops of the state had a capital of $5,516,453, they gave employment to over 4000 persons, and the value of their products was $6,946,567. These figures are exclusive of the numerous and large railway repair shops, the value of whose products was $5,839,445.

The manufacture of leather is another important industry. Large tanneries were attracted to the state, soon after the Civil War, by the abundance of tan bark in the forests, and the cheapness of labour. In 1905 $4,013,289 was invested in the manufacture of leather, and the products were valued at $3,583,871.

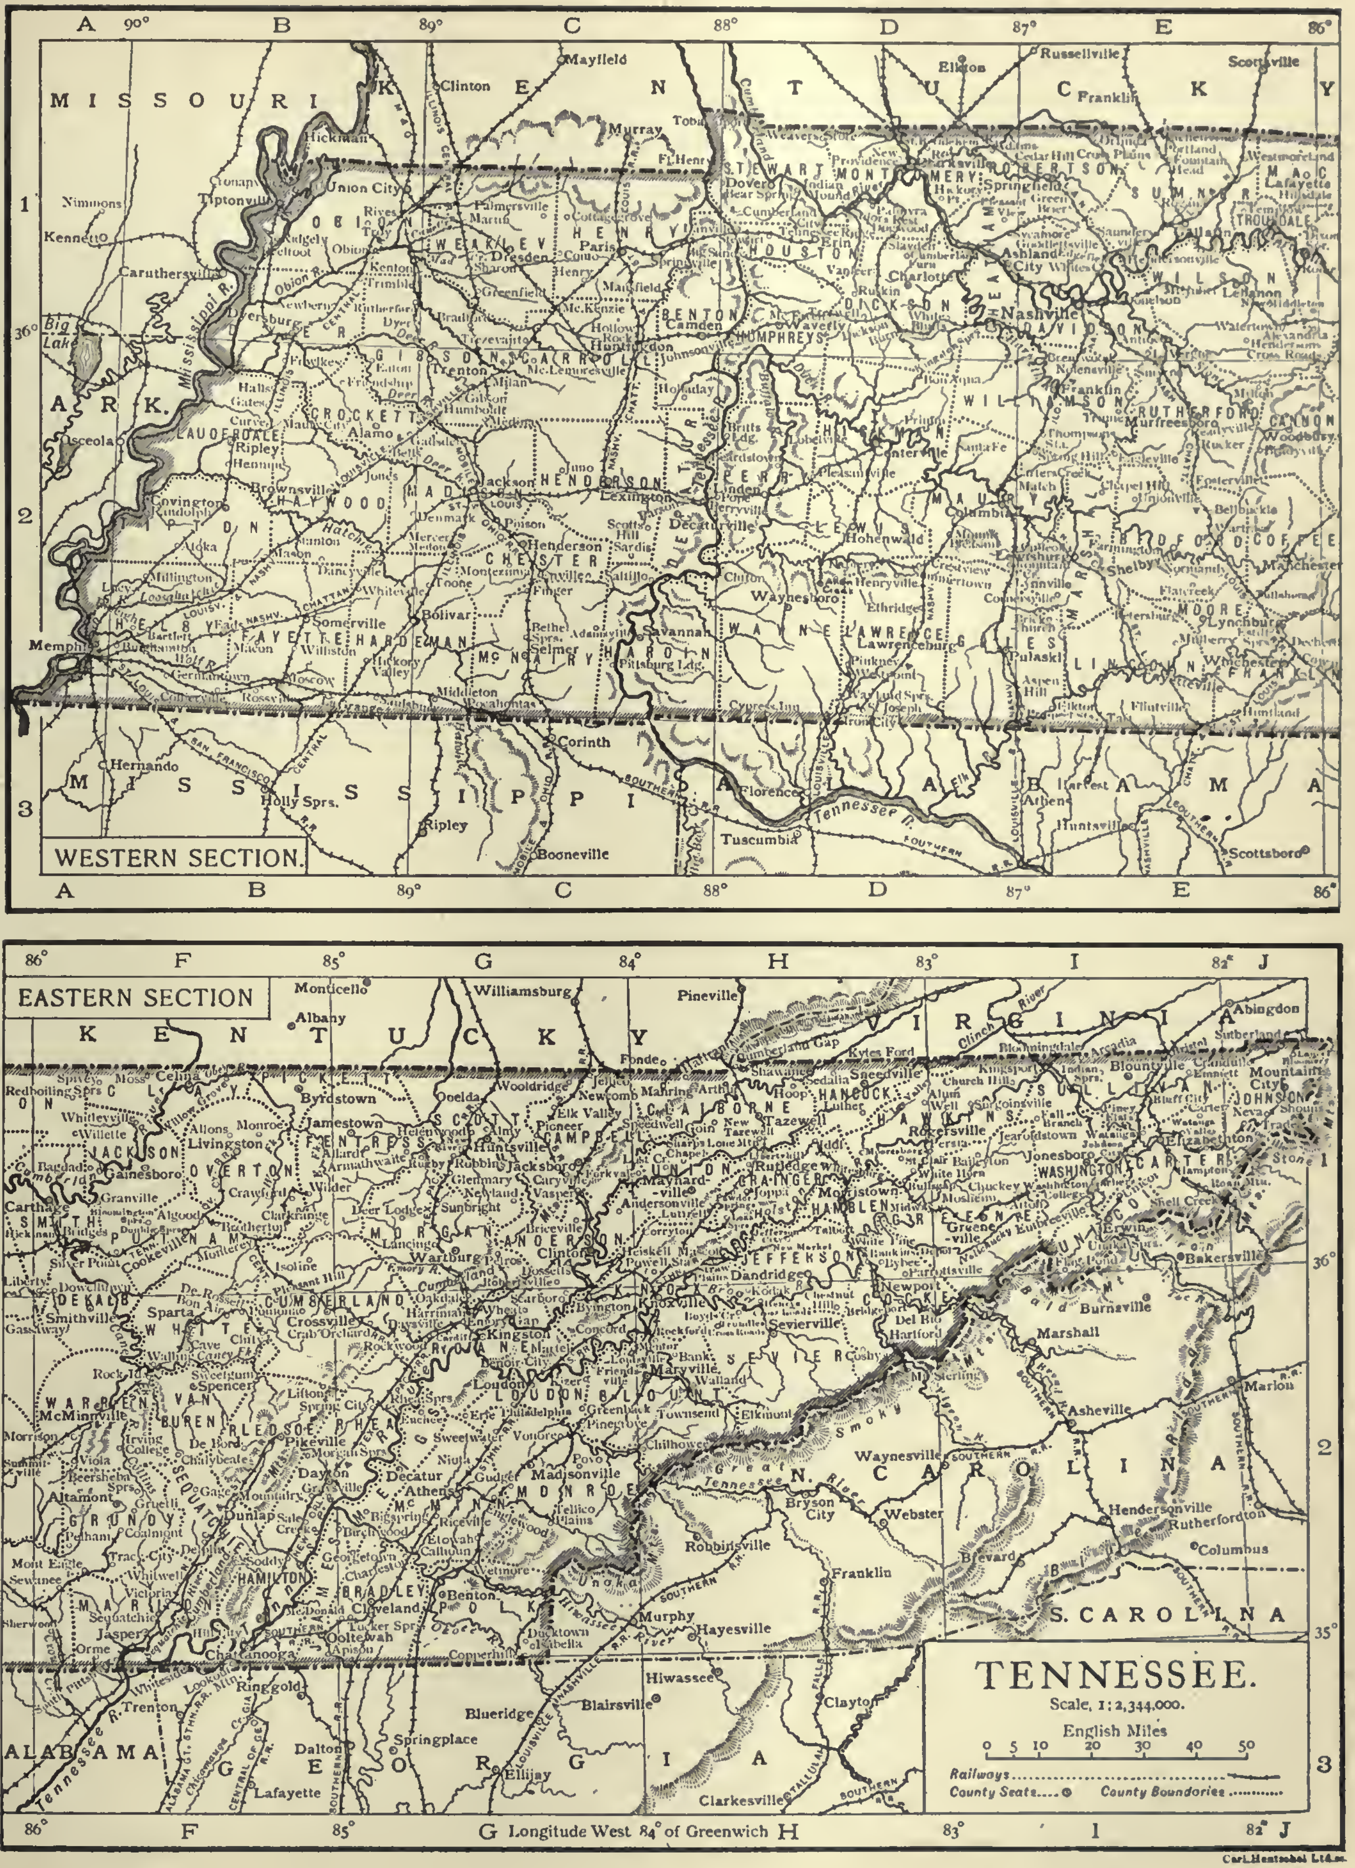
In 1905 the textile industry had an invested capital of $8,583,133, and a product valued at $6,895,203. The manufacture of cotton goods was the chief sub-division of the industry, employing 153,375 spindles, 3008 looms and 1787 knitting machines.

The printing and publishing industry of the state had an invested capital of $4,408,584 and products valued at $5,063,580. The manufacture of malt and distilled liquors employed (1905) a capital of $3,220,899, and the value of the product was $2,400,256. Among the other important manufacturing industries of the state and the value of their products in 1905 are: men's clothing, $2,961,581; patent medicines, $2,680,610; cotton-seed oil and oil cake, $3,743,927; tobacco, $404,241; artificial ice, $727,263; agricultural implements, $768,895; and coke, $809,801.

Transportation.—The railway mileage of Tennessee increased from 1253 m. in 1860 to 3184 in 1900, and 3480 on the 1st of January 1909. The principal railways operating in the state in 1910 were the Louisville & Nashville, the Nashville, Chattanooga & St Louis, the Cincinnati Southern and the Southern. The navigable waterways include the Mississippi river (which forms the western boundary of the state); the Tennessee river, navigable throughout its length, from Knoxville; and the Cumberland river, navigable throughout its length in the state. Chattanooga, Knoxville, Memphis and Nashville are ports of entry.

Population.—The total population in 1880 was 1,542,359; in 1890, 1,767,518; in 1900, 2,020,616; and in 1910, 2,184,789.[1] Of the total population in 1900, 1,522,600 were native whites, 17,746 were foreign-born, 480,243 were negroes, 108 were Indians, 75 were Chinese and 4 were Japanese. Of the inhabitants born in the United States 38,561 were born in Georgia, 36,052 in Kentucky, 28,405 in North Carolina, 27,709 in Alabama, and 25,953 in Virginia. Of the foreign-born 4569 were Germans, 3372 were Irish and 2207 were English. Of the total population 59,032 were of foreign parentage—*i.e.* either one or both parents were foreign-born—and 11,164 were of German, 9268 of Irish and 3532 of English parentage on both the father's and the mother's side. Of the total population of the state in 1906, 697,570 were members of religious denominations. There

[1] The populations in other census years were as follows: (1790), 35,691; (1800), 105,602; (1810), 261,727; (1820), 422,823; (1830), 681,904; (1840), 829,210; (1850), 1,002,717; (1860), 1,109,801; (1870), 1,258,520.



Carl Hentschel Ltd. sc.

were 277,170 Baptists, 241,396 Methodists, 79,337 Presbyterians, 56,315 Disciples of Christ, 17,252 Roman Catholics, 7874 Protestant Episcopalians, 3225 Lutherans, 2875 United Brethren and 2426 Congregationalists. From 1890 to 1900 the urban population (*i.e.* the population of places having 4000 inhabitants or more) increased from 219,792 to 285,886, or 30·1 per cent., the semi-urban population (*i.e.* the population of incorporated places, or the approximate equivalent, having less than 4000 inhabitants) increased from 87,351 to 114,837, 10·9 per cent. of the total increase in population; while the rural population (*i.e.* population outside of incorporated places) increased from 1,460,375 to 1,619,893, 63 per cent. of the total. The principal cities of the state, with population for 1910, are Memphis, 131,105; Nashville, 110,364; Chattanooga, 44,604 and Knoxville, 36,346.

Government.—Tennessee has had three constitutions, but the present one, adopted in 1870, is a reproduction of the second (1834) with only a few changes. Amendments may be proposed not oftener than once in six years by a majority of the members elected to each house of the legislature, but before they can be adopted they must be agreed to first by two-thirds of the members elected to each house of the next succeeding legislature, and later by a majority of all the citizens of the state voting for representatives at the next regular election. The legislature may, also, submit to the people the question of calling a convention to amend or revise the constitution, and such a convention must be called whenever, upon the submission of this proposition, a majority of the votes are cast in favour of it. Every attempt to amend or revise the present constitution has, however, been unsuccessful. The right of suffrage is given to every male citizen of the United States who has attained the age of twenty-one years and has been a resident of the state for one year, provided he has paid his poll tax and has not been convicted of bribery, larceny or other infamous crime. The election of the governor, members of the General Assembly and congressmen is held biennially, in even numbered years, on the first Tuesday after the first Monday in November, but the election of judicial and county officers is held on the first Thursday in August.

The governor is the only state executive officer who is elected by the people. He is elected for a term of two years and is not eligible for more than three consecutive terms. He must be at least thirty years of age and have been a citizen of the state for the last seven years before election. Although commander-in-chief of the state forces, he may call the militia into service only when there is a rebellion or an invasion and the General Assembly declares that the public safety requires it. The officers of the penitentiary and of the reformatory for boys are authorized to advise the governor with respect to an application for the pardon of an inmate of their institution, but he is not bound by their advice and there is no real restriction on his power to pardon except that he is not permitted to pardon in cases of impeachment. Among the more important officers appointed by the governor are the superintendent of public instruction, the commissioner of agriculture, statistics and mines, an assayer, state entomologist, and officers of the penitentiary. The governor may veto bills passed by the General Assembly, but to override his veto the vote of only a bare majority of the members elected to each house is required. The governor's salary is $4000 a year. There is no lieutenant-governor; in case of a vacancy in the office of governor the speaker of the Senate becomes acting governor. The secretary of state, the comptroller, and the treasurer are elected by a joint ballot of the Senate and the House of Representatives each for a term of two years; the attorney-general is appointed by the judges of the supreme court for a term of eight years.

Both senators and representatives are elected for a term of two years by counties or by districts having approximately the same population. The number of representatives is limited by the constitution to 99, and the number of senators to one-third the number of representatives. The qualifications prescribed for senators and representatives are that they shall have been citizens of the state for three years and residents of the county or district they are to represent for one year immediately preceding the election, and that senators shall be at least thirty years of age. The legislature meets biennially, in odd numbered years, on the first Monday in January, and the length of the session is limited by a provision that the members shall be paid four dollars a day, besides an allowance for travelling expenses, not to exceed 75 days; whenever the governor calls an extra session they are not paid for more than 20 days. Bills of whatever character may originate in either house, but no bill can become a law until it has passed both houses by a majority of all the members to which the house is entitled under the constitution, and if the governor vetoes a bill it cannot become a law until it has again passed both houses by such a majority. Only the more customary restrictions are placed upon the legislature by the constitution; such, for example, as that it shall pass no laws impairing the obligation of contracts, no *ex post facto* laws, no law authorizing imprisonment for debt, no law restraining the freedom of the press or freedom of speech, and that it shall not lend the credit of the state or make the state "owner in whole or in part of any bank or a stockholder with others in any association, company, corporation or municipality."

The administration of justice is vested in a supreme court, a court of civil appeals, chancery courts, circuit courts, county courts, justice of the peace courts, and, in certain cities and towns, a recorder's court. The supreme court consists of five judges elected by the state at large for a term of eight years, one for each of three grand divisions (eastern, middle and western) and two for the state at large. Each judge must be at least thirty-five years of age and have been a resident of the state for five years before his election. The judges designate one of their number to preside as chief justice. The court has appellate jurisdiction only. For the eastern district it sits at Knoxville; for the middle district at Nashville; and for the western district at Jackson. The concurrence of three judges is necessary to a decision. The court of civil appeals, which in 1907 was substituted for the court of chancery appeals, is also composed of five judges not more than two of whom shall reside in the same grand division. They are elected for a term of eight years, and each of them must be at least thirty years of age and have resided in the state for five years before election. This court has jurisdiction of appeals from equity courts in which the amount in controversy does not exceed $1000, except in cases involving the constitutionality of a Tennessee statute, contested election or state revenue, and ejectment suits; it has jurisdiction also of civil cases tried in the circuit and common law courts in which writs of error or appeals in the nature of writs of error are applied for. It may transfer any case to the supreme court or the supreme court may assume jurisdiction of any of its cases by issuing a writ of *certiorari*, but otherwise its decrees are final. The state is divided into twelve chancery districts in each of which a chancellor is elected for a term of eight years, and at every county-seat in each district a court of chancery is held. The court has exclusive original jurisdiction in equity cases in which the amount in controversy exceeds fifty dollars, concurrent jurisdiction with the county court in such matters as the administration of estates, the appointment and removal of guardians, and concurrent jurisdiction with the circuit courts in proceedings for divorce. The state is also divided into nineteen circuits, in each of which a circuit judge is elected for a term of eight years, and at every county-seat in each circuit a circuit court is held. The original jurisdiction of the circuit courts extends to all cases both civil and criminal not exclusively conferred upon some other court, and they have appellate jurisdiction in all suits and actions begun in the lower courts. In several of the counties the county court is composed of a county judge, elected for a term of eight years, together with the justices of the peace in the county, and in the other counties it consists of the justices of the peace alone. Its judicial business is principally the probate of wills and matters relating to the administration of estates. Each county is divided into civil districts varying in number according to population, and each district elects at least two justices of the peace for a term of six years; each county town or incorporated town also elects one justice of the peace. The jurisdiction of a justice of the peace, usually coextensive with the county, extends to the collection of notes of hand not exceeding $1000; to the settlement of accounts not exceeding $500; to suits for the recovery of property or suits demanding payment for damages, except for libel or slander, not exceeding $500; to equity cases in which the amount in controversy does not exceed $50; and to various other small cases. A recorder has concurrent jurisdiction with a justice of the peace.

Local Government.—The government of each county is vested principally in the county court. This body represents and acts for the county as a corporation; has charge of the erection and repair of county buildings; levies the county taxes, which are limited by law, however, to three mills on the dollar exclusive of those for schools, public highways, interest on the county debt, and other special purposes; divides the county into highway districts, and chooses a highway commissioner for each district for a term of two years; and chooses a superintendent of schools, a surveyor, a public administrator and public guardian, a board for the equalization of taxes, a coroner, a ranger, and a jail physician or health officer each for a term of two years, three commissioners of the poor for a term of three years (one each year), and a keeper and sealer of weights and measures to serve during its pleasure. A county trustee, whose duty it is to collect state and county taxes, and a sheriff are elected by the county for a term of two years; a clerk of the county court and a register are also elected by the county for a term of four years; and the county judge or chairman of the county court, the clerk of the county court, and the county health officer constitute a county board of health. In each civil district of a county which contains the county seat there are two constables, and in other civil districts of the county one constable elected for a term of two years. The general law for the incorporation of cities and towns vests the government of each municipality accepting its provisions principally in a mayor and two aldermen from each ward. All are elected for a term of two years, but one-half of the aldermen retire annually. The mayor and aldermen may appoint such officers as they consider necessary. The mayor may veto any action of the aldermen, and to override his veto a two-thirds majority is required.

Miscellaneous Laws.—For the protection of the property rights of married women the code of Tennessee provides that the wife's real estate shall be exempt from her husband's debts; that the proceeds of her real or personal property shall not be paid to any other person except by her consent certified upon privy examination of her by the court or a commissioner appointed by the court; and that she may mortgage or convey her real estate without the concurrence of her husband provided she be privately examined regarding the matter by a chancellor, circuit judge, or the clerk of the county court. When a husband dies his widow is entitled to a dower in one-third of his real estate, and, if there be not more than two children, to one-third of his personal estate; if there are more than two children her share of the personal estate is the same as that of each child. If a husband die intestate and leave no other heirs the widow is entitled to all his real estate in fee simple. When a wife dies leaving a husband of whom there has been issue born alive, he has by the courtesy a life interest in all her real estate and all her personal estate; if the wife die intestate and leave no other heirs the husband is entitled to all her real estate in fee simple. The causes for divorce are impotency, bigamy, adultery, desertion for two years, conviction of an infamous crime, the attempt of one of the parties to take the life of the other, the husband's cruel and inhuman treatment of his wife, refusal of the wife to remove with her husband into the state without a reasonable cause, pregnancy of the wife at the time of the marriage by another person without the knowledge of the husband, and habitual drunkenness, provided the habit has been contracted subsequent to the marriage. The plaintiff must be a resident of the state for two years before filing a petition for a divorce. If the husband is the plaintiff his interest in his wife's property is not impaired by the dissolution of the marriage, but the defendant wife forfeits all her interest in his property. Either party may marry again, but a defendant who has been found guilty of adultery is not permitted to marry the co-respondent during the life of the plaintiff. A homestead of a head of a family to the value of $1000 is exempt from forced sale except for the collection of taxes, debts contracted for its purchase or in making improvements upon it, or fines for voting out of the election district, for carrying concealed weapons, or for giving away or selling intoxicating liquors on election days. If the owner is married the homestead cannot be sold without the joint consent of husband and wife, and the wife's consent, as in other conveyances by married women, must be certified before the court or a commissioner appointed by the court. The homestead inures for the benefit of the widow and minor children. Ninety per cent. of the salary, wages or income of each person eighteen years of age or over is also exempt from attachment provided such salary, wages or income does not exceed $40 per month, and in any case $36 per month of the salary, wages or income of a person eighteen years of age or over cannot be attached. The employment of children under 14 years of age in any workshop, factory or mine within the state is forbidden by a law of 1901, and the employment of women or of boys under 16 years of age in any manufacturing establishment is limited to 60 hours a week by a law of 1907. Both the sale and the manufacture of intoxicating drinks are prohibited by law.

Charities, &c.—The charitable and penal institutions of the state consist of the Central Hospital for the Insane near Nashville; the Eastern Hospital for the Insane near Knoxville; the Western Hospital for the Insane near Bolivar; the Tennessee School for the blind at Nashville; the Tennessee Deaf and Dumb School at Knoxville; the Confederate Soldiers' Home near Nashville, on the "Hermitage," the estate formerly belonging to Andrew Jackson; and the Penitentiary and the Tennessee Industrial School, both at Nashville; and in 1907 the legislature passed an Act for the establishment in Davidson county of the Tennessee Reformatory for boys. Each hospital for the insane is governed by a board of five trustees appointed by the governor, with the consent of the senate, for a term of six years, and for the immediate supervision of each the trustees appoint a superintendent for a term of eight years. The Schools for the Blind and the Deaf and Dumb are each managed by a board of trustees, vacancies in which are filled by the remaining trustees with the concurrence of the legislature. The Confederate Soldiers' Home is managed by a board of fifteen trustees, of whom six are women, each serving until death or resignation, when his or her successor is appointed by the governor upon the recommendation of the corporation known as the Association of Confederate Soldiers. The Penitentiary is governed by a board of three prison commissioners, a superintendent, a warden, an assistant or deputy warden, a matron, a physician, and a chaplain, all appointed by the governor, the commissioners for a term of four years, the other officers for a term of two years. The prisoners are kept at labour principally in the state coal-mines, in manufacturing coke, on farms, or at contract labour within the prison walls; not more than 199 prisoners are to be leased to any one firm or corporation, or to be employed in any one business within the walls. The income to the state from the prison is greater than the disbursements for its maintenance. By good conduct a convict may shorten his term of service one month the first year, two months the second year, three months each year from the third to the tenth inclusive, and four months each subsequent year. The Industrial School, which is for orphan, helpless, wayward and abandoned children, is governed by a board of directors consisting of the governor, comptroller, secretary of state, and treasurer as *ex officio* members, and seven other members, a portion retiring every two years, and their successors being appointed by the remaining directors with the concurrence of the senate. The act for establishing the Tennessee Reformatory for Boys provides that the institution shall be governed by a board of trustees consisting of the governor and five other members, one retiring each year; that boys under eighteen years of age who are convicted of a penitentiary offence shall be sent to it; that the trustees may transfer incorrigible boys to the penitentiary, put others out in the service of citizens on probation, or recommend them to the governor for pardon. A general control of all public charities and correctional institutions is exercised by an unsalaried Board of State Charities consisting of the governor and six members appointed by him for a term of three years, two retiring every two years. The principal duties of this board are to examine the condition and the management of such institutions and report to the governor; and county and city authorities must submit to it for criticism all plans for new jails, public infirmaries, and hospitals.

Education.—For the administration of the common school system each county having five or more civil districts is divided into five school districts, and in counties having five or less than five civil districts each civil district constitutes a school district. Each school district elects one member of the county board of education, and in counties having less than five school districts one or more members of the county board, the number of which is always five, besides the county superintendent who is *ex officio* its secretary, are elected by the county at large, and to this county board of education together with district advisory boards is entrusted the management and control of the common schools. By the general education law enacted in 1909, 25 per cent. of the gross state revenue is paid into the general education fund, 61 per cent. of this fund is apportioned among the several counties according to their school population, and 10 per cent. of it constitutes a special fund to be apportioned among eligible counties in proportion to their school population but in inverse ratio to their taxable property; to have the use of any portion of this special fund a county must levy for the maintenance of common schools a tax not less than forty cents on each $100 of taxable property, a tax of $2 on each taxable poll, and such privilege taxes as the state permits it to levy for school purposes. Each county court may provide for one or more county high schools to be maintained in part by additional county taxes and miscellaneous funds, and 8 per cent. of the state school fund is set apart for the encouragement of counties in this matter. In 1908 there was a county high school in each of 23 counties, and in 1910 in each of 50 counties. The high schools are largely under the control of the state board of education, consisting of the governor (president), state superintendent of public instruction (secretary and treasurer), and six other members appointed by the governor. When the general education law was enacted in 1909 Tennessee had no state normal schools, but by the law 13 per cent. of the state educational fund is set apart for the establishment and maintenance of schools solely for the education and professional training of teachers for the elementary schools; one for white teachers in each of three grand divisions of the state, and one agricultural and industrial normal school for the industrial education of negroes and for preparing negro teachers for the common schools, and the management of these schools is vested in the state board of education. At the head of the state educational system is the University of Tennessee, which embraces a college of liberal arts, a graduate department, a college of engineering, a college of agriculture, a school of pharmacy, an industrial department, and a law department at Knoxville, and medical and dental departments at Nashville. The institution is governed by a board of trustees consisting of the governor, the state superintendent of public instruction, the commissioner of agriculture, the president of the university and twelve other members; two from the city of Knoxville and one from each congressional district, two elected each year. Seven per cent. of the general school fund is set apart for its maintenance; it was founded in 1794. For the higher education of teachers Tennessee has the Peabody College for Teachers, at Nashville, founded (1875) and maintained chiefly with proceeds from the George Peabody Fund for the improvement of education in the South. Other institutions of higher learning, not under the control of the state, are: the University of Nashville (non-sect., 1785); Washington and Tusculum College (non-sect., 1794), at Greenville; Maryville College (Presbyterian, 1819), at Maryville; Cumberland University (Presbyterian, 1842), at Lebanon; Burritt College (non-sect., 1848), at Spencer;

Hiwassee College (non-sect., 1849), at Sweetwater; Bethel College (Presbyterian 1850), at McKenzie; Carson and Newman College (Baptist, 1851), at Jefferson City; Walden University (Methodist, 1866), at Nashville; Fisk University (Congregational, 1866), at Nashville; University of Chattanooga (Methodist, 1867), at Chattanooga; University of the South (Protestant Episcopal, 1868), at Sewanee; King College (Presbyterian, 1869), at Bristol; Christian Brothers College (Roman Catholic, 1871), at Memphis; Knoxville College (United Presbyterian, 1875), at Knoxville; Milligan College (Christian, 1882), at Milligan; South-western Presbyterian College (1885), at Clarkville; and Lincoln Memorial University (non-sect., 1895), at Cumberland Gap.

Finance.—The state revenue is derived from a general property tax, a poll tax, an income tax, a tax on transfers of realty, an *ad valorem* tax on the average capital invested by merchants in their business, a privilege tax on merchants and many other occupations and businesses; a tax on litigation, levied on the unsuccessful party, a collateral inheritance tax, and fines and forfeitures. State, county and municipal taxes are assessed by a county assessor, who is elected for a term of four years, and one or more deputies whom the assessor is authorized to appoint. The law requires that all property shall be assessed at its full cash value, but personal property to the value of $1000 is exempt from taxation. Real estate is assessed biennially; personal property, privileges and polls annually. Assessments are examined and revised both by a county board of equalization and a state board of equalization. The county board consists of five members elected annually by the county court; justices of the peace are ineligible to election on this board, as are also all persons who have served on it within five years. The state board consists of the secretary of state, treasurer and comptroller. The clerk of the county court collects all taxes of persons, companies or corporations subject to a privilege tax; the county trustee the taxes of other persons. Three revenue commissioners, one of whom is an expert accountant, are elected biennially by each county court to examine the books and reports of the collectors, and three state revenue agents are appointed biennially by the comptroller to examine the records of all officials charged with the collection or disbursement of state or county revenue. The state revenue for the two years ending the 19th of December 1906 amounted to $3,804,740, and the cost of conducting the state government for these two years was $3,568,977. The bonded debt of the state grew from $16,643,666 on the 1st of October 1859 to $37,080,666 on the 1st of October 1869, but by the 19th of December 1906 it had been reduced to $14,236,766.

History.—The present site of Memphis may be the point where the Spanish explorer, Hernando de Soto, reached the Mississippi river, but this cannot be determined with certainty. Father Marquette in his voyage down the Mississippi camped upon the western border, and La Salle built Fort Prud'homme upon the Chickasaw Bluffs, probably on the site of Memphis, in 1682, but it was abandoned, then rebuilt, and again abandoned. The territory was included in the English grant to Sir Walter Raleigh in 1584 and in the later Stuart grants, including that of Carolina, in 1663. No permanent settlement, however, was made until 1769, though wandering explorers and fur traders visited the eastern portion much earlier. A party of Virginians led by Dr Thomas Walker (1715–1794), in 1750 reached and named the Cumberland river and mountains in honour of the royal duke. In 1756 or 1757, Fort Loudon, named in honour of John Campbell, earl of Loudon, was built on the Little Tennessee river, about 30 m. N. of the present site of Knoxville, as an outpost against the French, who were now active in the whole Mississippi Valley, and was garrisoned by royal troops. The fort was captured, however, by the Cherokee Indians in 1760, and both the garrison and the neighbouring settlers were massacred.

Eastern Tennessee was recognized as a common hunting ground by the Cherokees, Creeks, Miamis and other Indian tribes, and the Iroquois of New York also claimed a considerable portion by right of conquest. In 1768 the Iroquois ceded whatever claim they had to the English, and in 1769 several cabins were built along the Watauga and Holston rivers upon what was thought to be Virginian soil. A settlement near the present Rogersville was made in 1771 and in the next year another sprang up on the Nollichucky. After the failure of the Regulator insurrection in North Carolina in 1771, hundreds of the Regulators made their way into the wilderness. When the settlements were found to be within the limits of North Carolina, that colony made no effort to assert jurisdiction or to protect the settlers from Indian depredations. Therefore in 1772 the residents of the first two settlements met in general convention to establish a form of government since known as the Watauga Association. A general committee of thirteen was elected to exercise legislative powers. This committee elected from its members a committee of five in whom executive and judicial powers were lodged. The smaller committee elected a chairman, who was also chairman of the committee of thirteen. A sheriff, an attorney and a clerk were elected, and regulations for recording deeds and wills were made. Courts were held, but any conflict of jurisdiction with Virginia or North Carolina was avoided. In 1775 the settlement on the Nollichucky was forced to join the association, and in the same year the land was bought from the Indians in the hope of averting war. With the approach of the War of Independence, the dream of becoming a separate colony with a royal governor was abandoned, and on petition of the inhabitants the territory was annexed to North Carolina in 1776 as the Washington District, which in 1777 became Washington county, with the Mississippi river as the western boundary. The population increased rapidly and soon several new counties were created.

During the War of Independence the hardy mountaineers under John Sevier and Evan Shelby did valiant service against both the royal troops and the Loyalists in South Carolina, chiefly as partisan rangers under Charles McDowell (1743–1815). Major Patrick Ferguson with several hundred Loyalists and a small body of regulars, made a demonstration against the western settlements, but at King's Mountain in South Carolina he was completely defeated by the Americans, among whom Colonel Sevier and the troops led by him were conspicuous (see KING'S MOUNTAIN).

After the War of Independence the legislature of North Carolina in 1784 offered to cede her western territory to the general government, provided the cession should be accepted within two years. The Watauga settlers, indignant at this transfer without their consent, and fearing to be left without any form of government whatever, called a convention which met at Jonesborough on the 23rd of August 1784, and by which delegates to another convention to form a new state were appointed. Meanwhile North Carolina repealed the act of cession and created the western counties into a new judicial district. A second convention, in November, broke up in confusion without accomplishing anything; but a third adopted a constitution, which was submitted to the people, and ordered the election of a legislature. This body met early in 1785, elected Sevier governor of the new state of Franklin (at first Frankland), filled a number of offices, and passed several other acts looking to separate existence. Four new counties were created, and taxes were levied.[1] Later in the year another convention, to which the proposed constitution had been referred, adopted instead the constitution of North Carolina with a few trifling changes, and William Cocke was chosen to present to Congress a memorial requesting recognition as a state. Congress, however, ignored the request, and the diplomacy of the North Carolina authorities caused a reaction. For a time two sets of officials claimed recognition, but when the North Carolina legislature a second time passed an act of oblivion and remitted the taxes unpaid since 1784, the tide was turned. No successor to Sevier was elected, and he was arrested on a charge of treason, but was allowed to escape, and soon afterwards was again appointed brigadier-general of militia.

Meanwhile, settlers had pushed on further into the wilderness. On the 17th of March 1775 Colonel Richard Henderson and his associates extinguished the Indian title to an immense tract of land in the valleys of the Cumberland, the Kentucky and the Ohio rivers (see KENTUCKY). In 1778, James Robertson (1742–1814), a native of Virginia, who had been prominent in the Watauga settlement, set out with a small party to prepare the way for permanent occupation. He arrived at French

[1] On account of the scarcity of a circulating medium more than twenty articles were valued and declared legal tender. Among them were fox skins, 1s. 6d.; beaver skins, 6s.; bacon, 6d. the pound; rye whisky, 2s. 6d. the gallon.

Lick (so called from a French trading post established there) early in 1779, and in the same year a number of settlers from Virginia and South Carolina arrived. Another party led by John Donelson arrived in 1780, and after the close of the War of Independence, the immigrants came in a steady stream. A form of government similar to the Watauga Association was devised, and block-houses were built for defence against the Indians. Robertson was sent as a delegate to the North Carolina legislature in 1783 and through his instrumentality the settlements became Davidson county. Nashville, which had been founded as Nashborough in 1780, became the county seat. Finally, in 1843, it became the state capital. Robertson, the dominant figure in the early years, struggled to counteract the efforts of Spanish intriguers among the Indians, and when diplomacy failed led the settlers against the Indian towns.

On the 25th of February 1790 North Carolina again ceded the territory to the general government, stipulating that all the general provisions of the Ordinance of 1787 should apply except that forbidding slavery. Congress accepted the cession and, on the 26th of May 1790, passed an act for the government of the "Territory south of the River Ohio." William Blount was appointed the first governor, and in 1792 Knoxville became the seat of government. The chief events of Blount's administration were the contests with the Indians, the purchase of their lands, and the struggle against Spanish influence. A census ordered by the Territorial legislature in 1795 showed more than 60,000 free inhabitants (the number prescribed before the Territory could become a state), and accordingly a convention to draft a state constitution met in Knoxville on the 11th of January 1796. The instrument, which closely followed the constitution of North Carolina, was proclaimed without submission to popular vote. John Sevier was elected governor, and William Blount and William Cocke United States senators. In spite of the opposition of the Federalist party, whose leaders foresaw that Tennessee would be Republican, it was admitted to the Union as the sixteenth state on the 1st of June 1796.

With the rapid increase of population, the dread of Indian and Spaniard declined. Churches and schools were built, and soon many of the comforts and some of the luxuries of life made their appearance. The public school system was inaugurated in 1830, but not until 1845 was the principle of taxation for support fully recognized. As in all new states, the question of a circulating medium was acute during the first half of the 19th century, and state banks were organized, which suspended specie payments in times of financial stringency. The Bank of Tennessee, organized in 1838, had behind it the credit of the state, and it was hoped that money for education and for internal improvements might be secured from its profits. The management became a question of party politics, and during the Civil War its funds were used to advance the Confederate cause. The development of the western section along the Mississippi was rapid after the beginning of the century. Memphis, founded in 1819, was thought as late as 1832 to be in Mississippi, and not until 1837 was the southern boundary, which according to the North Carolina cession was 35°, finally established.[1] In common with other river towns, the disorderly element in Memphis was large, and the gamblers, robbers and horse thieves were only suppressed by local vigilance committees. The peculiar topographical conditions made the three sections of the state almost separate commonwealths, and demand for better means of communication was insistent.

The policy of state aid to internal improvements found advocates very early in spite of the Republican affiliations of the state, but a definite programme was not laid out until 1829, when commissioners for internal improvements were appointed and an expenditure of $150,000 was authorized. In 1835 the state agreed to subscribe one-third to the capital stock of companies organized to lay out turnpikes, railways, &c., and four years later the proportion became one-half. Though these agreements were soon repealed, the general policy was continued, and in 1861 more than $17,000,000 of the state debt was due to these subscriptions, from which there was little return.

Though President Andrew Jackson was for many years practically a dictator in Tennessee politics, his arbitrary methods and his intolerance of any sort of independence on the part of his followers led to a revolt in 1836, when the electoral vote of the state was given to Hugh Lawson White, then United States senator from Tennessee, who had been one of Jackson's most devoted adherents. White's followers called themselves Anti-Van Buren Democrats, but the proscription which they suffered drove most of them into the Whig party, which carried the state in presidential elections until 1856, when the vote was cast for James Buchanan, the Democratic candidate. The Whig party was so strong that James K. Polk (Democrat), a resident of the state, lost its electoral vote in 1844. With the disintegration of the Whig party, the state again became nominally Democratic, though Union sentiment was strong, particularly in East Tennessee. There were few large plantations and fewer slaves in that mountainous region, while the middle and western sections were more in harmony with the sentiment in Mississippi and Alabama. In 1850 representatives of nine Southern states met in a convention at Nashville (*q.v.*) to consider the questions at issue between the North and the South. The vote of the state was given for Bell and Everett in 1860, and the people as a whole were opposed to secession.

The proposition to call a convention to vote on the question of secession was voted down on the 9th of February 1861, but after President Lincoln's call for troops the legislature submitted the question of secession directly to the people, and meanwhile, on the 7th of May 1861, entered into a "Military League" with the Confederacy. An overwhelming vote was cast on the 8th of June in favour of secession, and on the 24th Governor I. G. Harris (1818–1897) issued a proclamation declaring Tennessee out of the Union. Andrew Johnson, then a United States senator from Tennessee, refused to resign his seat, and was supported by a large element in East Tennessee. A Union convention, including representatives from all the eastern and a few of the middle counties, met on the 17th of June 1861 and petitioned Congress to be admitted as a separate state. The request was ignored, but the section was strongly Unionist in sentiment during the war, and has since been strongly Republican.

The state was, next to Virginia, the chief battleground during the Civil War, and one historian has counted 454 battles and skirmishes which took place within its borders. In February 1862, General U.S. Grant and Commodore A. H. Foote captured Fort Henry on the Tennessee river, and Fort Donelson on the Cumberland. The Confederate line of defence was broken and General D. C. Buell occupied Nashville. Grant next ascended the Tennessee river to Pittsburg Landing with the intention of capturing the Memphis & Charleston railway, and on the 6th–7th of April defeated the Confederates in the battle of Shiloh. The capture of Island No. 10 in the Mississippi on the 7th of April opened the river as far south as Memphis, which was captured in June. On the 31st of December and the 2nd of January General William S. Rosecrans (Federal) fought with General Braxton Bragg (Confederate) the bloody but indecisive battle of Stone River (Murfreesboro). In June 1863 Rosecrans forced Bragg to evacuate Chattanooga. Bragg, however, turned upon his pursuer, and on the 19th and 20th of September one of the bloodiest battles of the war was fought at Chickamauga. General Grant now assumed command, and on the 24th and 25th of November defeated Bragg at Chattanooga, thus opening the way into East Tennessee. There General A. E. Burnside at first met with success, but was shut up in Knoxville by General James Longstreet, who was not able, however, to capture the city, and on the approach of General W. T. Sherman retired into Virginia. Almost the whole state was now held by Federal troops, and no considerable military movement occurred until after the fall of Atlanta in September 1864. Then General J. B. Hood moved into Tennessee, expecting Sherman

[1] For account of the settlement of the dispute over the northern boundary, see KENTUCKY.

to follow him. Sherman, however, sent reinforcements to Thomas and continued his march to the sea. Hood fought with General John M. Schofield at Franklin, and on the 15th–16th of December was utterly defeated by Thomas at Nashville, the Federals thus securing virtually undisputed control of the state.[1]

After the occupation of the state by the Federal armies in 1862 Andrew Johnson was appointed military governor by the president (confirmed March 3, 1862), and held the office until inaugurated vice-president on the 4th of March 1865. Republican electors attempted to cast the vote of the state in 1864, but were not recognized by Congress. Tennessee was the first of the Confederate states to be readmitted to the Union (July 24, 1866), after ratifying the Constitution of the United States with amendments, declaring the ordinance of secession void, voting to abolish slavery, and declaring the war debt void. The state escaped "carpet bag" government, but the native whites in control under the leadership of William G. Brownlow (1805–1877) confined the franchise to those who had always been uncompromisingly Union in sentiment and conferred suffrage upon the negroes (February 25, 1867). The Ku Klux Klan, originating in 1865 as a youthful prank at Pulaski, Tennessee, spread over the state and the entire South, and in 1869 nine counties in the middle and western sections were placed under martial law. At the elections in 1869 the Republican party split into two factions. The conservative candidate was elected by the aid of the Democrats, who also secured a majority of the legislature, which has never been lost since that time. The constitution was revised in 1870. For a considerable time after the war the state seemed to make little material progress, but since 1880 it has made rapid strides. The principal occurrences have been the final compounding of the old state debt at fifty cents on the dollar in 1882, the rapid growth of cities, and the increased importance of mining and manufacturing.

Governors of Tennessee

State of Franklin.	
John Sevier	1785–1788
Territory South of the Ohio	
William Blount	1790–1796
State of Tennessee.[2]

James B. Frazier,[6] „	1903–1905
John I. Cox, „	1905–1907
Malcolm R. Patterson, „	1907–1911
B. W. Hooper, Republican	1911–

[1] The state furnished 115,000 soldiers to the Confederate and 31,000 to the Union Army.

[2] The Constitutions of 1796, 1834 and 1870 all provided that the governor shall not serve more than six years in succession.

[3] Resigned.

[4] Forced to leave capital by invasion of Federal troops.

[5] Andrew Johnson, the governor, was inaugurated as Vice-President, March 4, 1865, thereby vacating the office.

[6] Resigned to enter the U.S. Senate.

Bibliography.—For a general physical description of the state see the *Reports of the Tennessee Geological Survey* (Nashville, 1840) and E. C. Hewett, *Geography of Tennessee* (no place, 1878). On administration see L. S. Merriam, *Higher Education in Tennessee*, in Circulars of Information of the United States Bureau of Education, No. 5 (Washington, 1893), and J. W. Caldwell, *Studies in the Constitutional History of Tennessee* (Cincinnati, 1895; new ed., 1907).

There is no satisfactory complete history of the state. The best is James Phelan's *History of Tennessee* (Boston, 1888). For the early period see John Haywood, *Civil and Political History* (Knoxville, 1823, reprinted Nashville, 1891); J. G. M. Ramsey, *Annals* (Charleston, 1853); A. W. Putnam, *History of Middle Tennessee, or Life and Times of General James Robertson* (Nashville, 1859); Theodore Roosevelt, *Winning of the West* (New York, 1889–1896); John Carr, *Early Times in Middle Tennessee* (Nashville, 1857). For the more recent period see O. P. Temple, *East Tennessee and the Civil War* (Cincinnati. 1899); James W. Fertig, *Secession and Reconstruction of Tennessee* (Chicago, 1898); and the *Report of Joint-Committee on Reconstruction* (U.S. Pub. Docs., Wash., 1866).

TENNESSEE RIVER, the largest tributary of the Ohio river, U.S.A. It is formed by the confluence of the Holston and the French Broad rivers 4·5 m. above Knoxville, Tennessee, flows S.S.W. to Chattanooga, there turns W. through the Cumberland Plateau and into the N.E. corner of Alabama, continues W. across the northern part of Alabama, turns N. on the boundary between Alabama and Mississippi, and continuing N. across Tennessee and Kentucky unites with the Ohio at Paducah. Its principal tributaries rise in the Appalachian Mountains: the Holston and the Clinch on the mountain slopes that flank the Appalachian Valley in western Virginia; and the French Broad, the Little Tennessee, and the Hiwassee in the mountains of western North Carolina. The Tennessee itself is 652 m. long, and with the Holston and the North Fork of the Holston forms a channel about 900 m. long. Its drainage basin covers about 44,000 sq. m., and its low water discharge at Paducah is 10,000 cu. ft. per second. Its average fall is 0·79 ft. per mile: 0·956 ft. from Knoxville to Chattanooga; 1·19 ft. from Chattanooga to Florence, Alabama; and 0·39 ft. from Florence to its mouth. The banks are everywhere easily accessible except at Knoxville and Chattanooga, where, for short distances, high elevations rise precipitously from the water; and as the banks are mostly of clay or rock the channel is permanent and the river is unusually free from silt.

The Tennessee is navigable by steamboats throughout its entire course of 652 m. for several months of the year; its tributaries have a nearly equal navigable mileage, and the main river and its tributaries together have a navigable mileage for rafts and flat-boats of 2400 m. At low water there are three obstructions to steamboat navigation in the main stream: the Colbert and Bee Tree shoals, just below Florence; the Muscle shoals just above Florence; and Hales Bar, 33 m. below Chattanooga. The state of Alabama, aided by the Federal government, constructed a lock canal, affording a depth of 5 ft., around the Muscle shoals in 1831–1836, but because of the obstructions above and below the canal was little used and was soon abandoned. The Federal government, beginning in 1868, completed the reconstruction of the Muscle Shoals Canal in two divisions (one 3·5 m. long with two locks, the other 14·5 m. long with nine locks, and both providing a depth of 5 ft.) in 1890, began in 1893 the construction of a canal, about 8 m. long and with one lock, around Colbert and Bee Tree shoals, and in 1904 authorized the construction with private capital of a lock and dam at Hales Bar to provide a channel 6 ft. deep at low water between it and Chattanooga, the water power to be used by the persons furnishing the capital. In 1905 a committee of the United States Senate recommended that future improvements of the river be made with a view of obtaining ultimately a channel having a minimum depth of 12 ft. at low water; and in 1907 Congress adopted a project for deepening to 5 ft. at low water the channel (145 m. long) between Hales Bar and the Muscle Shoals Canal. In 1908 the commerce carried on the Tennessee between

Chattanooga and Paducah amounted to 755,010 tons, valued at $18,752,180; it consisted chiefly of general merchandise, farm products, forest products and iron ore in the upper section, of general merchandise, cotton, timber products and grain in the middle section, and of general merchandise, farm products and timber products in the lower section.

During the Civil War Fort Henry was erected by the Confederates on the Tennessee river, in Tennessee just below the Kentucky state line, and on the 6th of February 1862 was captured by Com. A. H. Foote; Fort Donelson on the Cumberland, several miles east, was captured on the 16th by General U. S. Grant, and the two rivers were thus opened for the advance of the Federals far into Confederate territory.

TENNIEL, SIR JOHN (1820–), English humorous and satirical artist—specially identified with *Punch*—was born in London in 1820. He educated himself for his career, and although he became a probationer, and then a student, of the Royal Academy, he soon left the schools, where at that time there was little teaching. In 1836 he sent his first picture to the exhibition of the Society of British Artists, and in 1845 contributed a 16-ft. cartoon, "An Allegory of Justice," to the competition, held in that year, of designs for the mural decoration of the new Palace of Westminster. For this he received a £200 premium and a commission to paint a fresco in the Upper Waiting Hall (or "Hall of Poets") in the House of Lords. In spite of his tendency towards "high art," he was already known and appreciated as a humorist, and his early companionship with Charles Keene fostered and developed his talent for scholarly caricature. At Christmas time 1850 he was invited by Mark Lemon to fill the position of joint cartoonist (with John Leech) on *Punch*, from which Richard Doyle, offended by the attitude adopted by the paper towards the Papal see at the time of the so-called "aggression," had suddenly resigned. On the strength of his remarkable illustrations to Aesop's Fables, in which artistic power, humour of observation, and knowledge of animal life were equally apparent, Tenniel was selected, on Douglas Jerrold's initiative, to fill the breach, and he contributed his first drawing in the initial letter appearing on p. 224, vol. xix. His first "cartoon" was "Lord Jack the Giant Killer": it showed Lord John Russell, whose letter on the "aggression" had recently been published, valiantly assailing with the sword of truth and liberty Cardinal Wiseman armed with a crozier. In 1852 we find Tenniel's first superb lion, and his first obituary cartoon. Gradually he took over altogether the weekly drawing of the political "big cut," which John Leech was happy to resign into his hands in order to restrict himself to his pictures of life and character. Leech's work consisted for the most part of farce; Tenniel's was high comedy, and not infrequently tragedy; and the freedom of the humorist heightened the severer beauties of the satirist. When Leech died his friend continued his work alone, and except in 1864, 1868, and 1875–6–7–8, during short spells of illness or holiday, he did not miss a single week. About 2300 cartoons, innumerable minor drawings, double-page cartoons for *Punch's Almanac* and other special numbers, and 250 designs for *Punch's Pocket-books*, comprise the sum of Sir John Tenniel's work for the periodical in the service of which he spent the greater portion of his life. When Tenniel retired from the service of *Punch* in January 1901 he received the honour of a farewell banquet (12th June), at which Mr A. J. Balfour, then leader of the House of Commons, presided, and was supported by distinguished representatives of all that was best in English life. On that occasion Mr Balfour's description of Tenniel as "a great artist and a great gentleman" was applauded by the press of the whole country.

The main quality of Sir John Tenniel's work is accuracy of drawing, precision of touch, grace and dignity of conception, and—so far as such things can be compatible—geniality of satire. Tenniel raised the political cartoon into a classic composition, from which a sense of nobility is rarely absent. The beauty and statuesqueness of his ideal figures recall the influence, perhaps, of Cornelius and Overbeck—that German manner which was characteristic of many of our finer draughtsmen upon wood at the middle of the 19th century. But Tenniel's work is always original, unforced and fresh; and it never suggests, what is the fact, that the artist's work is drawn exclusively from memory, and never from the model. It may be mentioned that Tenniel's wonderful observation has been conducted, and his knowledge accumulated, literally through a single eye, the other having been lost during a fencing bout in his youth. It was in recognition not only of his ability as an artist in black and white, but of his service in infusing good humour and good taste into one phase of political life, that a knighthood was conferred upon him on Mr Gladstone's recommendation in 1893. Without pronounced political opinions of his own, Sir John Tenniel adopted in his work those of his paper, of which the Whig proclivities were to some degree softened by his pencil. The political history not of England only, but to some extent of the world, of half a century appears in Sir John Tenniel's weekly cartoons, which are dignified by a number of types invented by the artist, the classic beauty of which may be looked for in vain in kindred work by any previous cartoonist. (Take, for example, Sir John's famous picture of "Dropping the Pilot," which appeared in *Punch* on 20th March 1890, xcviii. 150–51.) Public exhibitions of Sir John Tenniel's work were held in 1895 and in 1900. Sir John Tenniel is also the author of one of the mosaics, "Leonardo da Vinci," in the South Court in the Victoria and Albert Museum; while his highly stippled water-colour drawings appeared from time to time in the exhibitions of the Royal Institute of Painters in Water Colours, of which society he was elected a member in 1874. As an illustrator on the wood-block he stands very high; his "Lalla Rookh" is perhaps the finest of all his work in point of conception, refinement, power and technical excellence.

WORKS ILLUSTRATED.—(1) *Juvenile Verse and Picture Book*, (1846); (2) *Undine* (1846); (3) *Aesop's Fables*, 100 drawings (1848); (4) Blair's *Grave* (1858); (5) Shirley Brooks's *The Gordian Knot* (1860), and (6) *The Silver Cord* (1861); (7) Moore's *Lalla Rookh*, 69 drawings (1861); (8) Lewis Carroll's *Alice's Adventures in Wonderland* (1866); (9) *The Mirage of Life*, 1867; (10) Carroll's *Through the Looking-Glass* (1870); and the following in collaboration: (11) Pollok's *Course of Time* (1857); (12) *Poets of the Nineteenth Century* (1857); (13) Poe's Works (1857); (14) *Home Affections* (1858); (15) Cholmondeley Pennell's *Puck on Pegasus* (1863); (16) *The Arabian Nights* (1863); (17) *English Sacred Poetry* (1864); (18) *Legends and Lyrics* (1865); (19) Tupper's *Proverbial Philosophy*; (20) Barry Cornwall's *Poems*, and other books. He also contributed to *Once a Week*, the Art Union publications, &c.

TENNIS (sometimes called royal tennis, and, in America, court tennis), one of the oldest of ball-games, and one of the most difficult to learn. It is now played in a walled and roofed court, 110 ft. by 38 ft. 8 in., the floor, however, measuring but 96 ft. by 31 ft. 8 in., the difference being the width of a roofed corridor, the "penthouse," which runs along the two end walls and one of the side walls. Across the middle of the court a net is stretched, and the first object of the game is to strike the ball over this with a bat or racquet. The net is 5 ft. high at the ends, 3 ft. 6 in. at the middle, and divides the floor into two equal parts, the "service" side and the "hazard" side. The floor and walls are made of cement and should be smooth but not polished.

The court is lighted from the roof and sides. The height of the court to the tie-beam is 30 ft., the height of the play-line, above which the ball must not go, 18 ft. at the sides and 23 ft. at the ends. The roof of the penthouse, which is made of wood, slopes downwards towards the court, the lower edge being 7 ft. 1½ in. from the floor, the upper 10 ft. 7 in., the width 7 ft. The illustrations show that each of the walls has its own peculiarities. The "dedans" is an opening in the end wall on the service side, under the penthouse, where provision is made for spectators, who are protected by a net. It is 21 ft. 8 in. in width; the upper edge is 6 ft. 10 in. from the floor, the lower edge 3 ft. 3 in. The opening of the dedans is 4 ft. 6 in. from the main wall, 5 ft. 6 in. from the other side wall. Looking from the dedans (*i.e.* from the service side), the right-hand or main wall has one peculiarity, the "tambour," a sloping buttress to form which the wall is built inward, reducing the breadth of that part of the court to 30 ft. 2 in. In the right-hand corner of the hazard side end wall (as viewed from the dedans) is the "grille," an opening lined with wood, 3 ft. 1 in. square; and on this wall is painted a continuation of the "pass-line." The left-hand wall, along which runs the pent-house, is not continuous, being broken by a long opening between the floor and the penthouse similar to the dedans, and at the same height from the ground. The low walls under this opening and the dedans are called the "batteries." There is no wall in front of the "marker's box," through which the court is entered on either side of the net-post. This long opening in the left-hand wall is divided into "galleries" and "doors," the latter situated where the entrances to the court used to be in early times. The measurements in order from the dedans are as follows, the numbers of the galleries being counted from the net: Service side—last gallery, 9 ft. 6 in.; second gallery, 9 ft. 6 in.; door, 3 ft. 6 in.; first gallery, 5 ft. 8 in.; marker's box or line-opening, 7 ft. 10 in.; hazard side—first gallery, 5 ft. 8 in.; door, 3 ft. 6 in.; second gallery, 9 ft. 6 in.;

last gallery (also called "winning" gallery), 9 ft. 6 in. The last galleries are 15 ft. 11 in. each from their respective end walls. The galleries are marked by "posts" which also serve to support the penthouse. The galleries, dedans and grille are known as the "openings"; three of these—the grille, dedans and winning gallery—are "winning-in openings"; for if a ball in play is struck into one of these, the striker scores a point. In the earlier French courts were other "winning openings," *l'ais* (the board), an upright board 9 ft. by 1 ft. in the left-hand corner of the dedans-wall, *le petit trou* or *le trou*, a hole 16 in. square at the bottom of the other side of that wall, and *la lune*, a round opening high up by the play-line, one at each end of the court. In the illustrations are shown certain lines painted on the floor, which are also continued perpendicularly on the walls. On the hazard side is the "half-court line," the "pass-line" and the "service-line." The first is only required when one player gives the other the odds of "half the court" (*vide infra*, "Scoring and Handicapping"). The pass-line is drawn 7 ft. 8 in. from the main wall; the service-line 21 ft. 1 in. from the grille-wall. The rectangle contained by the pass and service lines forms the "service-court." The other lines, both on the hazard side and service side, mark the "chases," which will be explained below. The cost of a tennis-court is about £2000.

The Implements.—The balls, for which there are no regulation dimensions, weigh $2\frac{1}{2}$ oz. and are $2\frac{1}{4}$ in. in diameter. They are made of strips of cloth, no twine being used except to keep the outside layer in place, and are covered with white Melton cloth. The American balls, made of layers of cotton and cloth alternately, are somewhat lighter and slower than the English. A set of balls consists of six or seven dozen; the same set should not be used twice in a day. The racquet is usually about 27 in. long and weighs about 16 oz. The head is about 9 in. long and 6 in. broad, but there are no restrictions as to size or weight. The head is somewhat pear-shaped; but its centre line does not correspond with the centre-line of the handle, as it is curved upwards to facilitate the stroke when the ball is taken close to the floor. The earliest racquets were strung diagonally, *i.e.* in diamonds; later the present vertical-horizontal stringing was adopted, then followed knotting at the points of intersection; but now the knotting has disappeared. The name *racquet* (or racket) appears in French as *racquette* and in Italian as *racchetta.* It is variously derived from Latin *reticulata* (netted), Dutch *racken* (to stretch), later Latin *racha* (palm of the hand or wrist), or the Arabian *ráhat* (palm of the hand): in favour of the two last derivations is the fact that tennis is a development of a game originally played with the hand, protected by a leather glove, and later on strings were stretched violin-fashion across the palm, to give more power to the stroke. Then followed a wooden bat (*battoir*), and then a short-handled racquet, either strung or covered with parchment, and finally the modern implement.

Technical Terms.—Some of these have already been explained, but the following may be added. "Bisque": the privilege, given as a form of odds, of scoring a stroke during any part of the game, except after the delivery of "service" or after a "fault." "Boast": to hit the ball on to the side wall first. "Cut": to strike the ball with the head of the racquet held at an angle to the ball's course instead of meeting it with the full face, thus causing backward rotation of the ball (similar to the "screw" in billiards), which alters its natural rebound from the wall. "Twist": analogous to "cut," but the strings are drawn across the ball at the moment of impact, so as to make it rotate sideways. A ball so struck with a fore-hand stroke twists inwards towards the other player off the floor, and away from him if it is allowed to strike the end wall; the reverse being the effect of twist from a back-hand stroke. "Rest": a series of strokes between the two players. "Service": the first stroke of a "rest." The server may serve from any part of the court on the service side. The ball must strike the roof of the side penthouse, and fall within the service-court. "Fault": a ball so served that it either does not touch the side penthouse, or falls outside the service-court. "Pass": a service in which the ball drops beyond the pass-line; the service in this case does not count, but a "pass" does not annul a previous fault, as was once the case. "Force": to strike the ball hard; a hard-hit stroke. "Volley": to strike a ball in its flight (*à la volée*) before it has touched the floor. "Half-volley": to strike a ball immediately after it touches, and before it rises from, the floor. "Nick": the angle where the floor and walls meet. "Marker": the attendant who marks and calls the chases and other points scored in the game.

Scoring and Handicapping.—A match consists of three or five "sets"; a "set" of eleven games. The winner of six games wins the set. If a player wins six games consecutively he wins a "love set," even though his opponent may have won several games. The loser of a love set, by an old custom, gives the marker a shilling. Should the score be called "Five games all," the players may arrange to play a "vantage game," the set in that case not being won till one or other has won two games in succession. A game consists ordinarily of four winning strokes, called by the marker as "Fifteen," "Thirty," "Forty," "Game"; if the score is "forty-all," the marker calls "Deuce," and two strokes have to be won in succession by one of the players. When one has won a stroke his score is called "Vantage"; if he wins the next, he wins the game; if he loses it, the score reverts to deuce. The score of the player who won the last stroke or made the last chase is called first. In handicapping the usual odds are (1) bisques, which may also be given in addition to other odds, or to balance odds received; (2) half-fifteen, or one point to be taken at the beginning of the second and every alternate game; (3) fifteen, or one point in every game; (4) half-thirty, or one point in every odd game and two points in every even game; (5) thirty, or two points in every game; (6) half-forty, or two points in every odd game and three in every even game; (7) forty, or three points in every game. Other handicaps are:—"Round services," the giver of odds having to serve so that the ball hits both the side and end penthouse; "half the court," the giver of the odds confining his strokes, except service, to one side of the court as divided by the half-court line, a stroke played into the other half counting to his adversary; "touch no walls," the giver of odds confining his play except service to the floor; "bar the openings," the giver of odds losing a point if his ball goes into a gallery or into the dedans or grille; "bar winning openings," which are closed to the giver of odds, who loses a point if the ball enters them; "side walls," the giver of odds losing a point if he plays the ball on to any side wall, the end penthouses being open to him, and the dedans and grille. In these "cramped" odds the rules do not apply if the ball goes out of limits after the second bound.

The Game and Hints on Play.—The players decide who shall serve by spinning a racquet on its head. One spins and the other calls "rough" or "smooth," the "rough" side of the head of the racquet showing the knots of some of the lower

strings. The winner takes the service side, service being an advantage. He serves from any part of the court, and in any way he thinks best, and the ball must go over the net, strike the side penthouse, and fall into the service-court (see "Fault" and "Pass"). His opponent ("striker-out") tries to return the ball over the net before it has touched the ground a second time; he may volley or half-volley it. For a stroke to be "good" it must be made before the second bound of the ball, and the ball must go over the net (even if it touches it), and must not strike the wall above the play-line, nor touch the roof or rafters. The first point to be attained is to be sure of getting the ball over the net, the next to do so in such a way as to defeat the opposing player's attempt to make a "good" stroke in return.

It often happens that a player, either intentionally or from inability, does not take or touch a ball returned to him over the net. In this event, chiefly on the service side, a "chase" (in Italian *caccia*, in French *chasse*) is made, the goodness or the badness of which depends upon the spot on the floor which the ball touches next after its first bound. The nearer this spot is to the end wall the better the chase. The chase lines are numbered, being one yard apart, the shorter lines representing the half-distance. The chases are noted and called by the marker. Thus if a ball fell on the line marked 4, he would call "chase four"; if between 4 and 3, he would call "Better than four" if it fell nearer to 4 than the short line, and "Worse than three" if it fell on the short line or between the short line and 3; for if the ball fall on a line the striker is credited with the better stroke. Strokes into the galleries and doors, with the exception of the winning gallery (last gallery, hazard side) count as chases. The making, or, in technical language, the "laying down" of a chase does not immediately affect the score: it has to be won first, *i.e.* the other player tries to make a better chase; if he fails, the original maker wins. For this purpose after two chases have been laid down (or one, if either player's score is at 40) the players change sides, *e.g.* if X has been serving and Y has laid down two chases, Y becomes the server and tries to defend them, X to win them by making the ball fall nearer to the back wall after its first bound than Y did. Either player wins the chase if he "finds" (*i.e.* hits the ball into) one of the winning openings, or if his opponent fails to make a good return. The winner of the chase scores a point. The chases are played off in the order in which they are made. Should X in trying to win a chase make the same chase as Y originally laid down, the chase is off and neither side scores. In France the chase is played again. The "rest" goes on till one of the players fails to make a good return, or deliberately leaves the ball alone in order that his opponent may lay down a chase (a procedure to be followed at the discretion of a player in whose judgment the chase will be a bad one), or lose a chase already laid down and in the course of being played off. Either player can score, there being no "hand-in" or "hand-out" as at racquets. A point is scored by that player whose opponent fails to make a good return stroke in a rest, or who strikes the ball into a winning opening, or wins a chase, or to whom two faults are served in succession. A player loses a stroke who strikes the ball twice, or allows it to touch himself or his clothes.

"He who would excel as a tennis-player must learn to serve," is the *dictum* of an amateur champion, but the necessary variations, the difference between the "railroad" and the "giraffe," &c., can only be explained by an experienced player and in the court. Variety is all-important, as is the knowledge of what sort of service is most valuable in defending a particular chase. All service should be heavily "cut." For the winning of hazard-side chases, indeed for all purposes, the "nick" service is useful, the endeavour being to make the service drop at the nick of the grille-wall and the floor. In attempting this service it should be remembered that it is better for the ball to hit the floor first than the wall, as this allows the cut to act. It is wise to cultivate one sort of service to perfection, if possible, with a reserve of others to suit the occasion. Again, the tennis "stroke," differing essentially as it does from the racquet stroke, can only be learnt in the court from a good teacher; but it is an axiom that tennis is not a game in which hard hitting necessarily tells, though force may be usefully employed in trying to "find" the winning openings. This, however, is an important point of etiquette—it is not "correct" to force for the dedans when the striker is close to the net, unless the force is "boasted" or there is no danger of hitting his opponent. In some clubs such a stroke is forbidden by a by-law. Some modern players play a faster and harder game than their predecessors, who considered strokes "on the floor," *i.e.* carefully judged chases, to be the true feature of the game; but in any case the beginner should remember that it is better to save his breath and to trust to winning an easy chase by-and-by than to run after a hard-hit stroke, which if left alone would leave "chase the door" or "second gallery" to be played for afterwards. Similarly in defending a chase, he should remember during the rest what that chase is, and not endeavour to return a stroke which would have lost it. Chases act as breathing-spaces, especially to the player who can trust to his skill "on the floor," and these, together with good service, form the reason why men can play tennis, and play it well, at a time of life when cricket, racquets and other active games have to be abandoned.

History.—Tennis may well be called a royal game, having been popular with various kings of England and France, though it is fanciful to connect it with Homer's Nausicaa, princess of Phaeacia (*Odyss.* vi. 115), who is represented by him as throwing, and not as hitting the ball to her maids of honour. In the ball-games of the Greeks and Romans we may see the rudiments of the French *jeu de paume*, which is undoubtedly the ancestor of modern tennis in a direct line. The origin of the name is quite obscure. Some give a numerical derivation from the fact that *la longue paume* was played by ten players, five on each side; others regard it as a corruption of *tamis* (sieve), for in a form of *la paume* the server bounced the ball on a sieve and then struck it: there is no possible reason for connecting "tennis" with the term Tenois, or Senois; most probable is the derivation from *Tenez!* (Take it! Play!), especially when we remember the large number of French terms that adhere to the game, *e.g.*, *grille*, *tambour* (drum, from the sound on the board that formed the face of that buttress) and *dedans*. Further, a poem dealing with the game, written in Latin elegiacs by R. Frissart, makes the striker cry "*Excipe!*" (Take it!) after each stroke: this seems to correspond with the custom which enjoins the racquet-marker to call "Play" whenever a legitimate stroke has been made. In the "Alexiad" of Anna Comnena (about A.D. 1120) is a reference to a game played on horseback in which a staff, curved at the end and strung with strings of plaited gut, was used. This game was played in a court called "a court for goff (*sic*)" (according to the *Lexicon of Alexandrine Greek*), and some similar game, corrupted through *tchangan* into *chicane*, was played in France. In A.D. 1300 the game was also known as *La boude*. Throughout the century indeed it was played in France and by the highest in the land: thus Louis X. died from a chill contracted after playing; Charles V. was devoted to the game, though he vainly tried to stop it as a pastime for the lower classes; Charles VI. watched the game from the room where he was confined during his attack of insanity, and Du Guesclin amused himself with it during the siege of Dinan. In England the game, or some form of it, was known, Chaucer possibly alluding to it in the words "But canstow playen racket to and fro"; and hand-ball, which may have been either tennis or cricket, was proscribed with other games by Edward III. in 1365. In France the game was prohibited to priests in A.D. 1245, and also in 1485, 1512 and 1673. In 1427 we hear of a woman named Margot, who was a skilful player, both her forehanded and backhanded strokes being commended; hence we may infer that the racquet had now been introduced. Tennis was at this time frequently played in some crude form in the moats of castles, where Charles VIII. used to watch the game. Henri II. is described as the best

Tennis Racquet.

player in France, and worthy of the silver ball given to the finest players. Later, Henri IV. and Louis XIV. (who kept a regular staff to look after his court) were patrons and players of tennis; indeed, in Henri IV.'s reign so popular was the sport that it was said that there were "more tennis-players in Paris than drunkards in England"; in the 16th century Paris alone could boast of 250 courts, yet it is stated that in 1879 there were only six courts in the whole of France. The word "tennis"—the game having hitherto been described as *luens pilae*—is first found in Gower's "Balade unto the worthy and noble kynge Henry the fourth" (1400), but Shakespeare's allusion to tennis as known to Henry V. must not be omitted. In reply to messengers from the dauphin, who had sent him a present of tennis-balls by their hands, Henry says:—

> "When we have match'd our rackets to these balls.
> We will, in France, by God's grace, play a set
> Shall strike his father's crown into the hazard.
> Tell him he hath made a match with such a wrangler
> That all the courts of France will be disturb'd
> With chases."
>
> —(*Henry V.*, Act i., sc. 2.)

Even if it be an anachronism that the poet should put these technical terms into the king's mouth, yet the fact is established that the terms were familiar in Elizabeth's time. Henry VII. indeed both played the game and revoked the edicts that forbade it; there was a court at Windsor Castle in his time, an open court with four bare walls, no penthouse, &c., being visible, and connected with the palace by a covered way. This court still existed in 1607. It was in that reign, possibly in that court, that the king of Castile played a match with the marquis of Dorset, the king, who used a racquet, conceding "fifteen" to the marquis, who played with his hand. The king won the set. Henry VIII. probably built the court at Hampton Court Palace. In 1615 there were further courts in London of various sizes, and a picture of James II. as a boy represents him standing in a tennis-court holding a short-handled racquet, strung diagonally. Pepys frequently alludes to tennis at a time when there were two courts at Oxford and five at Cambridge. Though the game flourished in the 19th century, it lost some of its popularity, mainly through the demolition of courts as building operations increased; moreover, courts complete in every detail alone were built, the play being consequently confined to the members of the clubs that could afford the expense. The last of the old courts to disappear stood in Windmill Street, at the top of the Haymarket, London. King Edward VII., when prince of Wales, frequently played tennis at "Prince's" Court.

The evolution of the court as now built is not easily traced, but courts undoubtedly existed side by side which differed from each other both in detail and in dimensions. It is generally assumed that such details as the penthouse, grille, galleries, &c., were deliberately planned to elaborate the game, but it is not unreasonable to suggest that the game, played , as it must often have been, in extemporized courts, took some of its modifications from them: it is at least significant that in an old illustration of *la paume* a miniature penthouse appears (from which the ball is rolling), apparently a shelter for a bell. The net does not appear till the 17th century, a rope, fringed or tasselled, being stretched across the court: further, the racquet was not in universal use in 1527, since Erasmus in his *Colloquies* says, "*Reticulum* (net, or racquet) *piscatoribus relinquamus: elegantius est palma uti*." An Italian, Antonio Scanio de Salo, is the first bibliographer of tennis. In his *Trattato della Palla* (treatise on the Ball) he mentions a large court for the game as played with a racquet, and a small court for the hand-game. The large court was 121 ft. long; it was entered by two doors, one between the first and second galleries on either side of the net; there were four galleries on each side; the dedans extended across the whole width of the court: the tambour was there and two grilles. He also mentioned chases, but these were decided by the place where the ball finally stopped, the spot being marked by a small movable standard. In another kind of court he says that there was no tambour, but two grilles. The penthouse was sometimes confined to two walls, sometimes to one, the end wall service side. In the hand-court one side was open all its length, with the exception of the battery and some pillars that perhaps gave variety to the stroke. The Latin poem to which allusion has been made shows the similarity of the 17th-century game to the modern: the racquet is spun; the marker (*signator*) is there to mark the chases (*metae*) with the movable standard; there is the grille (*fenestra*); the scoring by "15, 30, 40, game"; the volley (*volatu ludere*); the nick (*pedi ludere*, French *au pied*); the appeal to the spectators; the board (tatella, French *l'ais*); deuce and vantage, and the penthouse. In the 15th and 16th centuries tennis-balls were so largely imported from France that the Ironmongers' Company, who were the English manufactures, twice petitioned—the last time in 1591—for "protection" in the matter of balls. The term "bisk" (*bisque*, originally *bisquaye*) does not appear in English tennis till 1697 (Shadwell's *True Widow*), nor is the winning gallery mentioned before 1767. In the 17th century tennis became a spectacle in France, and the professional player came into existence, the most famous of that time being Le Pape, Clergé and Servo, and about the same time was formed the gild of *Paulmiers-racquetiers* (manufacturers of tennis material) with its arms, "Sable, a tennis-racquet proper; in a cross four tennis-balls of the same." De Garsault, writing in 1797, says, "*La Paume* is the only game that can take rank in the list of Arts and Crafts," and his book, *L'art du Paumier-Racquetier*, was adopted by the *Académie Royale*. In France very large sums of money were wagered on the game, especially at the end of the 16th century, the stakes being deposited under the cord or net, while in England, about 1750, there was so much betting and swindling, especially by professional players, that the game as played in the public courts fell into disrepute. In the middle of the 19th century, tennis-courts were rare indeed in England, the best known being those of the Marylebone Cricket Club (built in 1838), of the Messrs Prince in Hans Place, S.W., besides one at Brighton, one at Hampton Court, two at Cambridge, and one at Oxford; but the game progressed so fast that in 1910 there were between thirty and forty courts in England, one each in Ireland and Scotland, five in America, six in France, one in Melbourne (Australia) and one in Tasmania. The game has disappeared in Italy, Germany, Austria and Spain, though in Spain it was popular in the days of Philip III. (1578–1621) who was himself fond of playing.

The great French players mentioned above were followed by others—Cabasse (who invented the "boasted force" known as the *coup de Cabasse*), Barcellon, Farolais and Barnéon, and in the 18th century the Charniers, Bergeron and Masson, the last-named a really great player who could give fifteen to any of his contemporaries. One of his feats was to stand in a barrel before receiving the service, spring out of it and into it before and after each stroke. Other good players of later date were C. A. Delahaye, and greatest of all, J. E. Barre, who in 1855 re-opened the Versailles court, famous for the meeting of the *Tiers État* on the 20th of June 1789, which body there assembled and took the celebrated "Oath of the tennis-court." Masson is supposed to have visited England in 1792 and to have played against Messrs Hawkins and Price, and a professional called Pillet (or Pilet); but of Barre's visit there can be no doubt, as he played on the new court of the Marylebone Club in 1839, meeting "Peter" Tompkins, the English champion, and beating him so severely that when they met again next year Tompkins received the odds of thirty and a bisque. As an instance of the meagre interest taken in tennis at the time, Julian Marshall in his *Annals of Tennis* states that in *Bell's Life*, the leading sporting paper, Barre is reported as playing Cox and Tompkins "giving 7½ for a bisque," the tennis term "half fifteen" being arithmetically rendered. C. G. Taylor, the great cricketer, was one of the best amateurs, about this time. Barre eventually resigned the championship in favour of George Lambert, who was beaten in 1885 by T. Pettitt, of Boston U.S.A. Athletic Association, an Englishman by birth, who learnt all his tennis in America. Charles Saunders beat Lambert in 1886, thereby becoming champion of England. Pettitt and Saunders met for the championship of the world at Dublin, Pettitt winning by seven sets to five. The match took place in May 1890, and during the autumn, Pettitt declining to defend the title, Saunders assumed it, but five years later he was challenged by Peter Latham and beaten, Latham thus becoming the champion of the world both at racquets and tennis. An American, George Standing, challenged him in 1897 for the racquets championship, but was beaten, and next year Pettitt challenged Latham at tennis. In 1904 C. Fairs ("Punch") challenged Latham for the championship, but was beaten; but in 1908 Latham resigned his title, and Fairs then issued a challenge to any other player in the world to contest his right to the position of champion. The challenge was taken up in 1910 by G. F. Covey, the match for the championship, played at Brighton in the summer of 1910, being won by Fairs after a close contest, in which the younger player secured six sets to his opponent's seven, and fifty-three games to fifty-nine won by the champion. Among amateurs a formal championship was not established till 1889, the recognized champion being the winner of the gold prize annually given by the Marylebone Cricket Club to its members, the competition not being made "open" till 1896. For fifteen years, from 1867 to 1881, J. M. Heathcote held the title, among those whom he defeated during that period being such fine tennis-players as Julian Marshall, G. B. Crawley, the Hon. C. G. Lyttelton (afterwards Lord Cobham), R. D. Walker, C. E. Boyle, and the Hon. Alfred Lyttelton. In 1882 A. Lyttelton defeated Heathcote, only to be beaten next year by him, and to beat him in turn in 1884 and 1885; but in 1886 Heathcote (then fifty-three years of age) was again champion. From 1887 to 1895 inclusive the Hon. A. Lyttelton was champion, defeating during that time (besides Heathcote) A. J. Webbe, Sir Edward Grey and H. E. Crawley. Grey's perseverance—he won the silver prize on six occasions—was rewarded with the gold prize in 1896, but he was dispossessed in 1897 by E. H. Miles, who won for the next ten years, with the exception of 1900 when he was beaten by J. B. Gribble. On six occasions during this series Sir Edward Grey was second to the winner.

In 1889 the amateur championship, open to all amateurs, was instituted at Queen's Club, West Kensington. The following list shows the winners:—

1889. Sir E. Grey.	1900. E. H. Miles.
1890. E. B. Curtis.	1901. E. H. Miles.
1891. Sir E. Grey.	1902. E. H. Miles.
1892. H. E. Crawley.	1903. E. H. Miles.
1893. H. E. Crawley.	1904. V. Pennell.
1894. H. E. Crawley.	1905. E. H. Miles.
1895. Sir E. Grey.	1906. E. H. Miles.
1896. Sir E. Grey.	1907. Jay Gould.
1897. J. B. Gribble.	1908. Jay Gould.
1898. Sir E. Grey.	1909. E. H. Miles.
1899. E. H. Miles.	1910. E. H. Miles.

It may be mentioned that Heathcote and Lyttelton, who monopolized the Marylebone Club's gold prize for twenty-nine years, were strict adherents to the old-fashioned classical game, the winning and defending of chases and the clever placing of the ball being the leading feature of their game. A different and less attractive style of play, consisting of harder hitting, asserted itself in Miles's first success, which was followed by many others; but Jay Gould, an American amateur, who beat Miles for the championship in 1907 and again in 1908, owed his success to the perfection of his style in the older and more scientific tennis. He did not defend his title in 1909, when Miles again became amateur champion in his absence, a title which Miles again retained in 1910.

The universities of Oxford and Cambridge have played two matches, two-handed and four-handed, ever since 1859, with the exception of 1864 when neither match was played. The games are played at the court of the Marylebone Club.

Tennis in America.—Few tennis-courts existed in America before 1880, about which time the buildings of the Boston Athletic Association and the New York Racquet and Tennis Club were built. There are now also courts at Chicago, Tuxedo, Lakewood and several other places, but the game is naturally played by comparatively few persons. Tom Pettitt, mentioned above as for several years champion of the world, was for many years in charge of the Boston courts. Other first-class men are Alfred Tompkins of New York, Boakes of Chicago, and Forester. Richard Sears first won the American championship in 1892, and it has been won since by F. Warren, B. S. de Garmendia, L. M. Stockton (four times), Eustace Miles (champion of Great Britain), Joshua Crane, and Jay Gould (amateur champion 1907 and 1908). The older courts at Boston and New York are rather low and small, but the newer ones are perfect.

See J. M. Heathcote, *Tennis, Lawn Tennis, Rackets, Fives*, in "The Badminton Library," new and revised edition (London, 1903); *Racquets, Tennis and Squash*, by Eustace Miles (London, 1902).

TENNYSON, ALFRED TENNYSON, 1st Baron (1809–1892), English poet, was born at Somersby, Lincolnshire, on the 6th of August 1809. He was the fourth of the twelve children of the Rev. George Clayton Tennyson (1778–1831) and his wife Elizabeth Fytche (1781–1865). The Tennysons were an old Lincolnshire family settled at Bayon's Manor. The poet's grandfather, George Tennyson, M.P., had disinherited the poet's father, who was settled hard by in the rectory of Somersby, in favour of the younger son, Charles Tennyson D'Eyncourt. The rich pastoral scenery of this part of Lincolnshire influenced the imagination of the boy, and is plainly reflected in all his early poetry, although it has now been stated with authority that the localities of his subject-poems, which had been ingeniously identified with real brooks and granges, were wholly imaginary. At a very early age he began to write in prose and verse. At Christmas 1815 he was sent to the grammar school at Louth, his mother having kept up a connexion with this typical Lincolnshire borough, of which her father, the Rev. Stephen Fytche, had been vicar. Tennyson was at this school for five years, and then returned to Somersby to be trained by his father. In the rectory the boys had the run of an excellent library, and here the young poet based his wide knowledge of the English classics. The news of Byron's death (19th April 1824) made a deep impression on him: it was a day, he said, "when the whole world seemed to be darkened for me"; he went out into the woods and carved "Byron is dead" upon a rock. Tennyson was already writing copiously—"an epic of 6000 lines" at twelve, a drama in blank verse at fourteen, and so on: these exercises have, very properly, not been printed, but the poet said of them at the close of his life, "It seems to me, I wrote them all in perfect metre." The family was in the habit of spending the summer holidays at the coast of the county, commonly at Mablethorpe, and here Tennyson gained his impressions of the vastness of the sea. FitzGerald very justly attributed the landscape character of Tennyson's genius to the impress left on his imagination by "old Lincolnshire, where there were not only such good seas, but also such fine hill and dale among the wolds."

In 1827 Frederick Tennyson (1807–1898), the eldest surviving brother, uniting with his younger brothers Charles and Alfred, published at Louth an anonymous collection of *Poems by Two Brothers*. The "two" were Charles and Alfred (whose contributions predominated), and who shared the surprising profits, £20. On the 20th February 1828 Charles and Alfred matriculated at Trinity College, Cambridge, where Frederick was already a student. The poet subsequently told Mr Edmund Gosse that his father would not let him leave Somersby till, on successive days, he had recited from memory the whole of the odes of Horace. The brothers took rooms at 12 Rose Crescent, and afterwards moved into Trumpington Street (now 157 Corpus Buildings). They were shy, and made at first few friends; but they gradually gathered selected associates around them, and Alfred grew to be looked up to in Cambridge "as to a great poet and an elder brother" by a group which included Richard Chenevix Trench, Monckton Milnes (Lord Houghton), James Spedding, W. H. Thompson, Edward FitzGerald, W. H. Brookfield, and, above all, A. H. Hallam (1811–1833). Charles Tennyson (1808–1879) afterwards took the additional name of Turner. He published four volumes of sonnets which have been highly praised. In June 1829 Alfred Tennyson won the Chancellor's prize medal for his poem called "Timbuctoo." With great imperfections, this study in Miltonic blank verse displays the genius of a poet, in spite of a curious obscurity both of thought and style. Here are already both richness and power, although their expression is not yet clarified by taste. But by this time Tennyson was writing lyrics of still higher promise, and, as Arthur Hallam early perceived, with an extraordinary earnestness in the worship of beauty. The results of this enthusiasm and this labour of the artist appeared in the volume of *Poems, chiefly Lyrical*, published in 1830. This book would have been astonishing as the production of a youth of twenty-one, even if, since the death of Byron six years before, there had not been a singular dearth of good poetry in England. Here at least, in the slender volume of 1830, was a new writer revealed, and in "Mariana," "The Poet," "Love and Death," and "Oriana," a singer of wonderful though still unchastened melody. Through these, and through less perfect examples, was exhibited an amazing magnificence of fancy, at present insufficiently under control, and a voluptuous pomp of imagery, tending to an over-sweetness. The veteran S. T. Coleridge, praising the genius in the book, blamed the metrical imperfection of it. For this criticism he has himself constantly been reproved, and Tennyson (whose impatience of anything like censure was phenomenal) continued to resent it to the end of his life. Yet Coleridge was perfectly just in his remark; and the metrical anarchy of the "Madelines" and "Adelines" of the 1830 volume showed that Tennyson, with all his delicacy of modulation, had not yet mastered the arts of verse.

In the summer of 1830 Tennyson and Hallam volunteered in the army of the Spanish insurgent Torrijos, and marched about a little in the Pyrenees, without meeting with an enemy. He came back to find his father ailing, and in February 1831 he left Cambridge for Somersby, where a few days later Dr George Tennyson died. The new incumbent was willing that the Tennysons should continue to live in the rectory, which they did not leave until six years later. Arthur Hallam was now betrothed to Emily Tennyson (afterwards Mrs Jesse, 1811–1889), and stayed frequently at Somersby. This was a very happy time, and one of great physical development on Alfred's part. He took his share in all kinds of athletic exercises, and it was now that Brookfield said, "It is not fair that you should be Hercules as well as Apollo." This high physical zest in life seems to have declined after 1831, when his eyes began to trouble him, and he became liable to depression. The poetical work of these three years, mainly spent at Somersby, was given to the world in the volume of *Poems* which (dated 1833) appeared at the end of 1832. This was certainly one of the most astonishing revelations of finished genius ever produced by a young man of less than four-and-twenty. Here were to be read "The Lady of Shalott," "The Dream of Fair Women," "Oenone," "The Lotos-Eaters," "The Palace of Art," and "The Miller's Daughter," with a score of other lyrics, delicious and divine. The advance in craftsmanship and command over the *matériel* of verse shown since the volume of 1830 is absolutely astounding. If Tennyson had died of the savage article which presently appeared in the *Quarterly Review*, literature would have sustained terrible losses, but his name would have lived for ever among those of the great English poets. Indeed, it may be doubted whether, in several directions, he ever surpassed the glorious things to be found in this most exquisite and most precious book. It was well that its publication was completed before the blow fell upon Tennyson which took for a while all the light out of him. In August 1833 Arthur Hallam started with his father, the great historian, for Tirol. They went no farther than Vienna, where Mr Hallam, returning to the hotel on the 15th of September 1833, found his son lying dead on a sofa: a blood-vessel had broken in his brain. His body was brought back to England, and buried at Clevedon on the 3rd of January 1834. These events affected Tennyson extremely. He grew less than ever willing to come forward and face the world; his health became "variable and his spirits indifferent." The earliest effect of Hallam's death upon his friend's art was the composition, in the summer of 1834, of *The Two Voices;* and to the same period belong the beginnings of the *Idylls of the King* and of *In Memoriam*, over both of which he meditated long. In 1835 he visited the Lakes, and saw much of Hartley Coleridge, but would not "obtrude on the great man at Rydal," although "Wordsworth was hospitably disposed." Careless alike of fame and of influence, Tennyson spent these years mainly at Somersby, in a uniform devotion of his whole soul to the art of poetry. In 1837, to their great distress, the Tennysons were turned out of the Lincolnshire rectory where they had lived so long. They moved to High Beech, in Epping Forest, which was their home until 1840. The poet was already engaged, or "quasi-betrothed," to Emily Sellwood, but ten years more had to pass before they could afford to marry. At Torquay, in 1838, he wrote *Audley Court* on one of his rare excursions, for he had no money for touring, nor did he wish for change: he wrote at this time, "I require quiet, and myself to myself, more than any man when I write." In 1840 the Tennysons moved to Tunbridge Wells, and a year later to Boxley, near Maidstone, to be close to Edmund Lushington, who had now married Cecilia Tennyson. Alfred was from this time more and more frequently a visitor in London.

In 1842 the two-volume edition of his *Poems* broke the ten years' silence which he had enforced himself to keep. Here, with many pieces already known to all lovers of modern verse, were found rich and copious additions to his work. These he had originally intended to publish alone, and an earlier privately printed *Morte d'Arthur, Dora, and other Idylls*, of 1842, is the despair of book-collectors. Most of those studies of home-life in England, which formed so highly popular a section of Tennyson's work—such as "The Gardener's Daughter," "Walking to the Mail," and "The Lord of Burleigh"—were now first issued, and, in what we have grown to consider a much higher order, "Locksley Hall," "Ulysses," and "Sir Galahad." To the older and more luxurious lyrics, as reprinted in 1842, Tennyson did not spare the curbing and pruning hand, and in some cases went too far in restraining the wanton spirit of beauty in its youthful impulse. It is from 1842 that the universal fame of Tennyson must be dated; from the time of the publication of the two volumes he ceased to be a curiosity, or the darling of an advanced clique, and took his place as the leading poet of his age in England. Among the friends whom he now made, or for the first time cultivated, were Carlyle, Rogers, Dickens, and Elizabeth Barrett. Material difficulties now, however, for the first time intruded on his path. He became the victim of a certain "earnest-frothy" speculator, who induced him to sell his little Lincolnshire estate at Grasby, and to invest the proceeds, with all his other money, and part of that of his brothers and sisters, in a "Patent Decorative Carving Company": in a few months the whole scheme collapsed, and Tennyson was left penniless. He was attacked by so overwhelming a hypochondria that his life was despaired of, and he was placed for some time under the charge of a hydropathic physician at Cheltenham, where absolute rest and isolation gradually brought him round to health again. The state of utter indigence to which Tennyson was reduced greatly exercised his friends, and in September 1845, at the suggestion of Henry Hallam, Sir Robert Peel was induced to bestow on the poet a pension of £200 a year. Never was public money expended in a more patriotic fashion. Tennyson's health slowly became restored, and in 1846 he was hard at work on *The Princess;* in the autumn of this year he took a tour in Switzerland, and saw great mountains and such "stateliest bits of landskip" for the first time. In 1847 nervous prostration again obliged him to undergo treatment at Prestbury: "They tell me not to read, not to think; but they might as well tell me not to live." Dr Gully's water-cure was tried, with success. *The Princess* was now published, in a form afterwards considerably modified and added to. Carlyle and FitzGerald "gave up all hopes of him after *The Princess*," or pretended that they did. It was true that the bent of his genius was slightly altered, in a direction which seemed less purely and austerely that of the highest art; but his concessions to public taste vastly added to the width of the circle he now addressed. The home of the Tennysons was now at Cheltenham: on his occasional visits to London he was in the habit of seeing Thackeray, Coventry Patmore, Browning and Macready, as well as older friends, but he avoided "society." In 1848, while making a tour in Cornwall, Tennyson met Robert Stephen Hawker of Morwenstow, with whom he seems—but the evidence is uncertain—to have talked about King Arthur, and to have resumed his intention of writing an epic on that theme. In his absent-minded way Tennyson was very apt to mislay objects; in earlier life he had lost the MS. of *Poems, chiefly Lyrical*, and had been obliged to restore the whole from scraps and memory. Now a worse thing befell him, for in February 1850, having collected into one "long ledger-like book" all the elegies on Arthur Hallam which he had been composing at intervals since 1833, he left this only MS. in the cupboard of some lodgings in Mornington Place, Hampstead Road. By extraordinary good chance it had been overlooked by the landlady, and Coventry Patmore was able to recover it. In this way *In Memoriam* was dragged back from the very verge of destruction, and could be published, in its original anonymous form, in May 1850. The public was at first greatly mystified by the nature and object of this poem, which was not merely a chronicle of Tennyson's emotions under bereavement, nor even a statement of his philosophical and religious beliefs, but, as he long afterwards explained, a sort of *Divina Commedia*, ending with happiness in the marriage of his youngest sister, Cecilia Lushington. In fact, the great blemishes of *In Memoriam*, its redundancy and the dislocation of its parts, were largely due to the desultory manner of its composition. The poet wrote the sections as they occurred to him, and did not think of weaving them together into a single poem until it was too late to give them real coherency. The metre, which by a curious naïveté Tennyson long believed that he had invented, served by its happy peculiarity to bind the sections together, and even to give an illusion of connected movement to the thought.

The sale of Tennyson's poems now made it safe for him to settle, and on the 13th of June 1850 he was married at Shiplake to Emily Sarah Sellwood (1813–1896). Of this union no more need be said than was recorded long afterwards by the poet himself, "The peace of God came into my life before the altar when I wedded her." Every species of good fortune was now to descend on the path of the man who had struggled against ill luck so long. Wordsworth died, and on the 19th of November 1850 Queen Victoria appointed Tennyson poet laureate. The salary connected with the post was very small, but it had a secondary value in greatly stimulating the sale of his books, which was his main source of income. The young couple took a house at Warninglid, in Sussex, which did not suit them, and then one in Montpelier Row, Twickenham, which did better. In April 1851 their first child was born dead. At this time Tennyson was brooding much upon the ancient world, and reading little but Milton, Homer and Virgil. This condition was elegantly defined by Carlyle as "sitting on a dungheap among innumerable dead dogs." In the summer of 1851 was made the tour in Italy, of which *The Daisy* is the immortal record. Of 1852 the principal events were the birth of his eldest son Hallam, the second Lord Tennyson, in August, and in November the publication of the *Ode on the Death of the Duke of Wellington*. In the winter of 1853 Tennyson entered into possession of a little house and farm called Farringford, near Freshwater, in the Isle of Wight, which he leased at first, and afterwards bought: this beautiful place, ringed round with ilexes and cedars, entered into his life and coloured it with its delicate enchantment. In 1854 he published *The Charge of the Light Brigade*, and was busy composing *Maud* and its accompanying lyrics; and this volume was published in July 1855, just after he was made D.C.L. at Oxford: he was received on this occasion, which may be considered his first public appearance, with a "tremendous ovation." The reception of *Maud* from the critics, however, was the worst trial to his equanimity which Tennyson had ever had to endure, nor had the future anything like it in store for him. He had risen in *Maud* far above his ordinary serenity of style, to ecstasies of passion and audacities of expression which were scarcely intelligible to his readers, and certainly not welcome. It is odd that this irregular poem, with its copious and varied music, its splendid sweep of emotion, its unfailing richness of texture—this poem in which Tennyson rises to heights of human sympathy and intuition which he reached nowhere else, should have been received with bitter hostility, have been styled "the dead level of prose run mad," and have been reproved more absurdly still for its "rampant and rabid bloodthirstiness of soul." There came a reaction of taste and sense, but the delicate spirit of Tennyson had been wounded. For some years the world heard nothing from him; he was at Farringford, busying himself with the Arthurian traditions. He had now become an object of boundless personal curiosity, being already difficult to find, and the centre of amusing legends. It was in 1857 that Bayard Taylor saw him, and carried away the impression of a man "tall and broad-shouldered as a son of Anak, with hair, beard and eyes of southern darkness." This period of somewhat mysterious withdrawal from the world embraced a tour in Wales in 1857, a visit to Norway in 1858, and a journey through Portugal in 1859. In 1857 two Arthurian poems had been tentatively and privately printed, as *Enid and Nimue, or the True and the False*, to see how the idyllic form would be liked by the inner circle of Tennyson's friends. In the summer of 1859 the first series of *Idylls of the King* was at length given to the world, and achieved a popular success far beyond anything experienced before by any English poets, save perhaps Byron and Scott. Within a month of publication, 10,000 copies had been sold. The idyls were four in number, "Enid," "Vivien" (no longer called "Nimue"), "Elaine" and "Guinevere." These were fragments of the epic of the fall of King Arthur and the Table Round which Tennyson was so long preparing, and which he can hardly be said to have ever completed, although nearly thirty years later he closed it. The public and the critics alike were entranced with the "sweetness" and the "purity" of the treatment. A few, like Ruskin, were doubtful about "that increased quietness of style"; one or two already suspected that the "sweetness" was obtained at some sacrifice of force, and that the "purity" involved a concession to Victorian conventionality. It was not perceived at the time that the four idyls were parts of a great historical or mystical poem, and they were welcomed as four polished studies of typical women: it must be confessed that in this light their even perfection of workmanship appeared to greater advantage than it eventually did in the general texture of the so-called "epic." In 1859 "Boadicea" was written, and "Riflemen, Form!" published in *The Times*. Urged by the duke of Argyll, Tennyson now turned his attention to the theme of the Holy Grail, though he progressed with it but fitfully and slowly. In 1861 he travelled in Auvergne and the Pyrenees, with Clough, who was to die a few months later; to this year belong "Helen's Tower" and the "Dedication" of the *Idylls* to the prince consort, "These to his Memory." The latter led to Tennyson's presentation in April 1862 to the queen, who "stood pale and statue-like before him, in a kind of stately innocence," which greatly moved his admiring homage. From this time forth the poet enjoyed the constant favour of the sovereign, though he could never be moulded into a conventional courtier. He now put the Arthurian legends aside for a time, and devoted himself to the composition, in 1862, of "Enoch Arden," which, however, did not appear until 1864, and then in a volume which also contained "Sea Dreams," "Aylmer's Field" and, above all, "The Northern Farmer," the first and finest of Tennyson's remarkable studies in dialect. In April of this year Garibaldi visited Farringford; in February 1865 Tennyson's mother died at Hampstead in her eighty-fifth year; in the ensuing summer he travelled in Germany. The time slipped by with incidents but few and slight, Tennyson's popularity in Great Britain growing all the time to an extent unparalleled in the whole annals of English poetry. This universality of fame led to considerable practical discomfort; he was besieged by sightseers, and his nervous trepidation led him perhaps to exaggerate the intensity of the infliction. In 1867 he determined to make for himself a haven of refuge against the invading Philistine, and bought some land on Blackdown, above Haslemere, then a secluded corner of England; here Mr (afterwards Sir) James Knowles began to build him a house, ultimately named Aldworth. This is the time of two of his rare, privately printed pamphlets, *The Window; or, the Loves of the Wrens* (1867), and *The Victim* (1868). The noble poem *Lucretius*, one of the greatest of Tennyson's versified monographs, appeared in May 1868, and in this year *The Holy Grail* was at last finished; it was published in 1869, together with three other idyls belonging to the Arthurian epic, and various miscellaneous lyrics, besides *Lucretius*. The reception of this volume was cordial, but not so universally respectful as that which Tennyson had grown to expect from his adoring public. The fact was that the heightened reputation of Browning, and still more the sudden vogue of Swinburne, Morris and Rossetti (1866–1870), considerably disturbed the minds of Tennyson's most ardent readers, and exposed himself to a severer criticism than he had lately been accustomed to endure. He went on quite calmly, however, sure of his mission and of his music. His next volume (1872), *Gareth and Lynette* and *The Last Tournament*, continued, and, as he then supposed, concluded *The Idylls of the King*, to the great satisfaction of the poet, who had found much difficulty in rounding off the last sections of the poem. Nor, as he was to find, was the poem yet completed, but for the time being he dismissed it from his mind. In 1873 he was offered a baronetcy by Gladstone, and again by Disraeli in 1874; in each case the honour was gracefully declined. Believing that his work with the romantic Arthurian epics was concluded, Tennyson now turned his attention to a department of poetry which had long attracted him, but which he had never seriously attempted—the drama. He put before him a scheme, which he cannot be said to have carried far, that of illustrating "the making of England" by a series of great historical tragedies. His *Queen Mary*, the first of these chronicle-plays was published in 1875, and played by Sir Henry Irving at the Lyceum in 1876. Although it was full of admirably dramatic writing, it was not theatrically well composed, and it failed on the stage. Extremely pertinacious in this respect, the poet went on attempting to storm the theatre, with assault upon assault, all practically failures until the seventh and last, which was unfortunately posthumous. To have really succeeded on the stage would have given Tennyson more gratification than anything else, but he was not permitted to live long enough to see this blossom also added to the heavy garland of his glory. Meanwhile *Harold*, a tragedy of doom, was published in 1876; but, though perhaps the finest of its author's dramas, it has never been acted. During these years Tennyson's thoughts were largely occupied with the building of Aldworth. His few lyrics were spirited ballads of adventure, inspired by an exalted patriotism—"The Revenge" (1878), "The Defence of Lucknow" (1879)—but he reprinted and finally published his old suppressed poem, *The Lover's Tale*, and a little play of his, *The Falcon*, versified out of Boccaccio, was produced by the Kendals at their theatre in the last days of 1879. Tennyson had reached the limits of the threescore years and ten, and it was tacitly taken for granted that he would now retire into dignified repose. In point of fact, he now started on a new lease of poetical activity. In 1880 he published the earliest of six important collections of lyrics, this being entitled *Ballads and other Poems*, and containing the sombre and magnificent "Rizpah." In 1881 *The Cup* and in 1882 *The Promise of May*, two little plays, were produced without substantial success in London theatres: the second of these is perhaps the least successful of all the poet's longer writings, but its failure annoyed him unreasonably. This determination to be a working playwright, pushed on in the face of critical hostility and popular indifference, is a very curious trait in the character of Tennyson. In September 1883 Tennyson and Gladstone set out on a voyage round the north of Scotland, to Orkney, and across the ocean to Norway and Denmark. At Copenhagen they were entertained by the king and queen, and after much fêting, returned to Gravesend: this adventure served to cheer the poet, who had been in low spirits since the death of his favourite brother Charles, and who now entered upon a phase of admirable vigour. During the voyage Gladstone had determined to offer Tennyson a peerage. After some demur, the poet consented to accept it, but added, "For my own part, I shall regret my simple name all my life." On the 11th of March 1884 he took his seat in the House of Lords as Baron Tennyson of Aldworth and Farringford. He voted twice, but never spoke in the House. In the autumn of this year his tragedy of *Becket* was published, but the poet at last despaired of the stage, and disclaimed any hope of "meeting the exigencies of our modern theatre." Curiously enough, after his death *Becket* was the one of all his plays which enjoyed a great success on the boards. In 1885 was published another interesting miscellany, *Tiresias and other Poems*, with a posthumous dedication to Edward FitzGerald. In this volume, it should be noted, *The Idylls of the King* was completed at last by the publication of "Balin and Balan"; it contained also the superb address "To Virgil." In April 1886 Tennyson suffered the loss of his second son, Lionel, who died in the Red Sea on his return from India. The untiring old poet was steadily writing on, and by 1886 he had another collection of lyrics ready, *Locksley Hall Sixty Years After*, &c.; his eyes troubled him, but his memory and his intellectual curiosity were as vivid as ever. Late in 1888 he had a dangerous attack of rheumatic gout, from which it seemed in December that he could scarcely hope to rally, but his magnificent constitution pulled him through. He was past eighty when he published the collection of new verses entitled *Demeter and other Poems* (1889), which appeared almost simultaneously with the death of Browning, an event which left Tennyson a solitary figure indeed in poetic literature. In 1891 it was observed that he had wonderfully recovered the high spirits of youth, and even a remarkable portion of physical strength. His latest drama, *The Foresters*, now received his attention, and in March 1892 it was produced at New York, with Miss Ada Rehan as Maid Marian. During this year Tennyson was steadily engaged on poetical composition, finishing "Akbar's Dream," "Kapiolani" and other contents of the posthumous volume called *The Death of Oenone*, 1892. In the summer he took a voyage to the Channel Islands and Devonshire; and even this was not his latest excursion from home, for in July 1892 he went up for a visit to London. Soon after entering his eighty-fourth year, however, symptoms of weakness set in, and early in September his condition began to give alarm. He retained his intellectual lucidity and an absolute command of his faculties to the last, reading Shakespeare with obvious appreciation until within a few hours of his death. With the splendour of the full moon falling upon him, his hand clasping his Shakespeare, and looking, as we are told, almost unearthly in the majestic beauty of his old age, Tennyson passed away at Aldworth on the night of the 6th of October 1892. *Cymbeline*, the play he had been reading on the last afternoon, was laid in his coffin, and on the 12th he was publicly buried with great solemnity in Westminster Abbey. Lady Tennyson survived until August 1896.

The physical appearance of Tennyson was very remarkable. Of his figure at the age of thirty-three Carlyle has left a superb portrait: "One of the finest-looking men in the world. A great shock of rough, dusky, dark hair; bright, laughing, hazel eyes; massive aquiline face, most massive yet most delicate; of sallow brown complexion, almost Indian-looking, clothes cynically loose, free-and-easy, smokes infinite tobacco. His voice is musical, metallic, fit for loud laughter and piercing wail, and all that may lie between; speech and speculation free and plenteous; I do not meet in these late decades such company over a pipe." He was unusually tall, and possessed in advanced years a strange and rather terrifying air of sombre majesty. But he was, in fact, of a great simplicity in temperament, affectionate, shy, still exquisitely sensitive in extreme old age to the influences of beauty, melancholy and sweetness. Although exceedingly near-sighted, Tennyson was a very close observer of nature, and at the age of eighty his dark and glowing eyes, which were still strong, continued to permit him to enjoy the delicate features of country life around him, both at Aldworth and in the Isle of Wight. His *Life*, written with admirable piety and taste by his son, Hallam, second Lord Tennyson, was published in two volumes in 1897.

At the time of his death, and for some time after it, the enthusiastic recognition of the genius of Tennyson was too extravagant to be permanent. A reaction against this extravagance was perhaps inevitable, and criticism has of late been little occupied with the poet. The reason of this is easy to find. For an unusually long period this particular poetry had occupied public and professional opinion, and all the commonplace things about it had been said and re-said to satiety. It lacks for the moment the interest of freshness; it is like a wonderful picture seen so constantly that it fails any longer to concentrate attention. No living poet has ever held England—no poet but Victor Hugo has probably ever held any country—quite so long under his unbroken sway as Tennyson did. As he recedes from us, however, we begin to see that he has a much closer relation to the great Georgian writers than we used to be willing to admit. The distance between the generation of Wordsworth and Coleridge and that of Byron and Shelley is not less—it is even probably greater—than that which divides Keats from Tennyson, and he is more the last of that great school than the first of any new one. The qualities in which he seems to surpass his immediate predecessors are exactly those which should be the gift of one who sums up the labours of a mighty line of artists. He is remarkable among them for the breadth, the richness, the substantial accomplishment of his touch; he has something of all these his elders, and goes farther along the road of technical perfection than any of them. We still look to the earlier masters for supreme excellence in particular directions: to Wordsworth for sublime philosophy, to Coleridge for ethereal magic, to Byron for passion, to Shelley for lyric intensity, to Keats for richness. Tennyson does not excel each of these in his own special field, but he is often nearer to the particular man in his particular mastery than any one else can be said to be, and he has in addition his own field of supremacy. What this is cannot easily be defined; it consists, perhaps, in the beauty of the atmosphere which Tennyson contrives to cast around his work, moulding it in the blue mystery of twilight, in the opaline haze of sunset: this atmosphere, suffused over his poetry with inestimable skill and with a tact very rarely at fault, produces an almost unfailing illusion or mirage of loveliness, so that, even where (as must sometimes be the case with every poet) the thought and the imagery have little value in themselves, the fictive aura of beauty broods over the otherwise undistinguished verse. Hence, among all the English poets, it is Tennyson who presents the least percentage of entirely unattractive poetry. In his luminous subtlety and his broad undulating sweetness, his relationship with Virgil has long been manifest; he was himself aware of it. But he was also conscious that his exquisite devotion to mere lucidity and beauty might be a snare to him, and a happy instinct was always driving him to a study of mankind as well as of inanimate nature. Few English writers have known so adroitly as Tennyson how to bend the study of Shakespeare to the enrichment of their personal style. It should be added that he was a very deep and original student of literature of every description, and that the comparatively few specimens which have been preserved of his conversation contain some of the finest fragments of modern appreciation of the great poets which we possess. This is worthy of consideration in any attempt made to sketch the mind of a man who was above all other masters of recent literature an artist, and who must be studied in the vast and orbic fullness of his accomplishment in order to be appreciated at all. (E. G.)

Alfred, Lord Tennyson: a Memoir (1897), by Hallam, second Baron Tennyson, is the authoritative source for the poet's biography. Mr R. H. Shepherd in his *Tennysoniana* (1866), supplied a list of criticisms on his work, and a bibliography issued separately in 1896. Among the numerous books on the subject of his life and writings may be mentioned: *A Commentary on Tennyson's In Memoriam* (1901), by Prof. A. C. Bradley; Canon Rawnsley's *Memories of the Tennysons* (1900); *Alfred Tennyson* (1901), by Mr Andrew Lang; an essay on "The Mission of Tennyson" in Mr W. S. Lilly's *Studies in Religion and Literature* (1904); and *The Life of Lord Tennyson* (1904), by Mr A. C. Benson, who gives a more critical estimate of the poet than was possible in the Memoir by his son.

TENOR (through Fr. and It. from Lat. *tenor*, holding on, course, sense of a law, tone), a general course or direction, the drift or general meaning of a statement or discourse, hence, in law, the true purport and effect of a deed or instrument. The most general use of the word is, in music, for the highest kind of the natural adult male voice. This use descends from the Medieval Latin *tenor*, which was applied first to the chief melody, the *cantus firmus*, and then to the male voice to which the singing of this was assigned.

TENREC (*Centetes ecaudatus*), one of the largest representatives of the mammalian order Insectivora, the length being from 12 in. to 16 in.; called also the tailless ground-hog of Madagascar, to which island it is restricted. The coat consists chiefly of bristles and hairs, with an admixture of flexible spines, which in the young form longitudinal lines down the back; but in the adult they are limited to the back of the neck. The general hue is brown tinged with yellow. From twelve to sixteen young are produced at a birth, and twenty-one have been recorded. In habits the tenrec is fossorial and nocturnal; its home is in the brush in the mountain regions, and in the cool season, from May or June till December, it hibernates in deep burrows. The long flexible snout is used to root up worms and grubs, and ground-insects form part of its nourishment. These animals are very fat when hibernation begins, and are then much valued for food by the natives (see also INSECTIVORA).

TENT. A tent is a portable habitation or place of shelter, consisting in its simplest form of a covering of some textile substance stretched over a framework of cords and poles, or of wooden rods, and fastened tightly to the ground by pegs. Throughout the greater part of the interior of Asia the pastoral tribes have of necessity ever been dwellers in tents—the scantiness of water, the consequent frequent failure of herbage, and the violent extremes of seasons compelling a wandering life. Tents have also been used in all ages by armies in campaign. In ancient Assyrian sculptures discovered by Layard at Nineveh the forms of tent and tent-furnishings are similar to those which still prevail in the East, and it appears that then as now it was a custom to pitch tents within the walls of a city. The ordinary family tent of the Arab nomads of modern times is a comparatively spacious ridged structure, averaging from 20 to 25 ft. in length, but sometimes reaching as much as 40 ft. Its covering consists of a thick felt of black goat hair (cp. Cant. i. 5—"black as the tents of Kedar"), or sometimes of alternate stripes of black and white disposed horizontally. The ridge or roof is supported by nine poles disposed in sets of three, the central set being loftier than those at each end, whereby a slope outward is formed which helps to carry off rain. The average height inside at the centre is 7 ft. and at the sides 5 ft., and the cloths at the side are so attached that they can easily be removed, the sheltered end being always kept open. Internally the tent is separated by a partition into two sections, that reserved for the women containing the cooking utensils and food. The *jourt* or tent of the Kirghiz of Central Asia is a very capacious and substantial structure, consisting of a wooden frame for sides, radiating ribs for roof, and a wooden door. The sides are made up of sections of laths, which expand and contract in lozenges, on the principle of lazy tongs, and to their upper extremities ribs are lashed at regular intervals. Over this framework a heavy covering of felt is thrown, which is either weighted down with stones or, when necessary, stitched together.

In Western countries tents are used chiefly in military encampments, by travellers and explorers, and for temporary ceremonial occasions and public gatherings. The material of which they are composed is commonly a light linen canvas or navy duck; but for tents of small size stout cotton canvas is employed, being light, strong, elastic, and sufficiently waterproof. These tents vary in size from a low-pitched covering, under which a couple of men can with difficulty creep, up to spacious marquees, in which horticultural and agricultural shows are held, and which can accommodate thousands of persons.

The marquee is distinguished from the tent by being a ridged structure, devoted to show and social uses; but the humblest tent made—the *tente d'abri* or shelter tent of the French army—is also ridged in form. The *tente d'abri* affords sleeping accommodation for six men, and consists of a rope stretched over three low poles and fixed into the ground. Four separate squares of canvas buttoned together are thrown over the rope and pegged to the ground on each side so as to form a low ridge. Two other squares are used for covering the ends, being thrown over the slanting rope ends by which the poles are pegged to the ground. Each of the six men using the tent carries one of the squares of canvas besides his quota of the poles, rope and pegs. In the British service *tentes d'abri* are often improvised by fastening together blankets or waterproof sheets over a stick. The gipsies and travelling tinkers of England have an equally unpretentious tent, which consists of a framework, of hazel rods bent so as to form a series of low ridges, the ends being stuck into the ground, and over this frame blankets or other coverings are thrown and pegged down. The simplest, but at the same time the least convenient, of ordinary tents is the conical, consisting of a central pole with ropes and canvas radiating from it in an unbroken slope to the ground. The common army bell tent is of this type, but the conical roof terminates at about 1 ft. 9 in. from the ground, and from it there hangs vertically a curtain which is loosely pegged to the ground or looped up to allow of the free circulation of air when the tent is unoccupied or the weather is favourable. This form, however, covers much ground in proportion to the accommodation it affords, as the space round the circumference is of little value. A tent, therefore, which has sides or a fall is a much more convenient structure. The counterpart of the conical is the pyramidal tent, the four equal sides sloping to the ground; and this form with a fall or sides makes the square tent, which is both convenient in shape and firm in structure. Small tents are also made, modified from the Arab form, with a central pole and two lower lateral poles. In the umbrella tent the roof is supported by a set of ribs which radiate from the pole, precisely as the ribs of an umbrella spread out from the stick.

The tents and marquees in use in the British army are the following: The bell tents (single or double thickness) 16 ft. in circumference, accommodating in active service 3 officers, 7 sergeants or 15 men each; the Indian general service tents, of various sizes, square with pyramidal roofs, the Indian "E.P." and "Staff-sergeants'" tents, which are much roomier than the tents used in India on active service, "hospital marquees" and "operating tents."

In former wars, when small professional armies were employed and it was customary to pay extraordinary attention to the soldier's comforts, the train of an army included a full tent equipment, which helped to diminish the already small degree of mobility of which it was capable. Under the Revolution and Napoleon, and generally in the 19th century, the system of housing armies in the field under canvas was practically abolished (except as regards more or less rough *tentes d'abri*) and replaced by that of billets and bivouacs. The strain entailed upon the transport by complete tentage may be judged from the fact that a single battalion on the minimum scale would require four waggons, each with one ton load of poles and canvas, that is, the regimental transport would be doubled.

A tent equipment (of the *tente d'abri* type) was introduced into the German army about 1888, and the troops of Austria and Switzerland also possess tents. In the Russian army cavalry and engineer troops are excepted from the otherwise universal issue of canvas shelter.

TENTERDEN, CHARLES ABBOTT, 1st Baron (1762–1832), lord chief justice of England, was born at Canterbury on the 7th of October 1762, his father having been a hairdresser and wigmaker of the town. He was educated at Canterbury King's School and Corpus Christi College, Oxford, of which he afterwards became fellow and tutor. On the advice of Mr Justice Buller (1746–1800), to whose son he had been tutor, he determined on the legal profession, and entered at the Middle Temple in 1787. For several years he practised as a special pleader under the bar, and was finally called at the Inner Temple in 1796. He joined the Oxford circuit and soon made rapid headway. In 1801 he was appointed recorder of Oxford. In 1802 appeared his *Law relative to Merchant Ships and Seamen*, a concise and excellent treatise, which has maintained its position as an authoritative work. Its publication brought to him so much commercial and other work that in 1808 he was in a position to refuse a seat on the bench; this, however, he accepted in 1816, being made a judge of the court of common pleas. On the resignation of Lord Ellenborough in 1818 he was promoted to the chief justiceship of the king's bench. In his capacity as chief justice he presided over several important state trials, notably that of Arthur Thistlewood and the Cato Street conspirators (1820). He was raised to the peerage in 1827 as Baron Tenterden of Hendon. Never a great lawyer and with no pretence to eloquence, Tenterden made his way by sound common sense and steady hard work. He was an uncompromising Tory, and had no sympathy with the reform of the criminal law carried out by Romilly; while he strongly opposed the Catholic Relief Bill and the Reform Bill. He died on the 4th of November 1832, and was buried, by his own desire, in the Foundling Hospital, London, of which he was a governor.

Tenterden was succeeded in his title by his son, John Henry Abbott (1796–1870), then by his grandson, Charles Stuart Aubrey Abbott (1834–1882), permanent under-secretary for foreign affairs, who was made a K.C.B. in 1878. In 1882 the latter's son, Charles Stuart Henry Abbott (b. 1865) became the 4th Baron.

TENTERDEN, a market town and municipal borough in the Ashford parliamentary division of Kent, England, 62 m. S.E. by E. of London by the South-Eastern and Chatham railway. Pop. (1901) 3243. It lies on an elevation above the Newnill Channel, a tributary of the Rother, whose flat valley, called the Rother Levels, was an estuary within historic times; and even as late as the 18th century the sea was within 2 m. of Tenterden, which is a member of the affiliated Cinque Port of Rye. The church of St Mildred is Early English and later, and its tall, massive Perpendicular tower is well known for the legend connecting it with Goodwin Sands. The story is that the Abbot of St Augustine, Canterbury, diverted the funds by which the sea-wall protecting Earl Godwin's island was kept up, for the purpose of building Tenterden steeple, the consequence being that in 1099 an inundation took place and "Tenterden steeple was the cause of the Goodwin Sands." Attached to the church is a penitentiary used in the reign of Queen Mary for the confinement of persons awaiting trial on a charge of heresy. The church of High Halden, in the neighbourhood, is remarkable for its octagonal wooden tower constructed of huge timbers, with a belfry of wooden tiles (shingles), of the time of Henry VI. Tenterden has a considerable trade in agricultural produce and stock. It is governed by a mayor, four aldermen and twelve councillors. Area, 8946 acres.

Tenterden (*Tenterdenne*, *Tentyrden*) figures frequently in contemporary records from 1300 onwards. In 1449 Henry VI. incorporated it by the name of a "Bailiff and Commonalty," and united it to Rye. In return for these and other privileges it was to contribute towards the services due from the latter as one of the Cinque Ports. The troubles of 1449 apparently hindered the issue of the charter, since in 1463 Edward IV. brought it into operation. In 1600 it was incorporated under the title of the "Mayor, Jurats and Commons" of the town and hundred of Tenterden, in the county of Kent, the members of the corporation ranking henceforward as barons of the Cinque Ports. A weekly corn market on Friday and a yearly fair on the first Monday in May were granted, both of which are held at the present day. In 1790 a contemporary writer mentions the market as being little frequented, whilst the fair was large and resorted to by all the neighbourhood. This charter was exemplified by that of the year 1700. The size and importance of Tenterden can be estimated from a receipt of 1635 for £90 ship-money, as compared with £70 contributed by Faversham, and £60 by Hythe. Under Edward III. several refugee Flemings settled in the town and established the woollen manufacture. An old waste book, still preserved, contains entries of amounts of cloth sent from Tenterden to London. By 1835 this trade had completely died out, and Tenterden was suffering from the depression of agricultural interests.

TENURE (Fr. *tenure*, from Lat. *tenere*, to hold), in law, the holding or possession of land. The holding of land in England was originally either *allodial* or *feudal*. Allodial land was land held not of a superior lord, but of the king and people. Such ownership was absolute. It possibly took its origin from the view that the land was the possession of the clan; that the chief was the leader but not the owner, and was no doubt strengthened by the temporary and partial occupation by the Romans. Their withdrawal, followed by the Saxon invasion, tended, without doubt, to re-establish the principle of common village ownership which formed the basis of both Celtic and German tenure. In the later Saxon period, however, private ownership became gradually more extended. Then the feudal idea began to make progress in England, much as it did about the same time on the continent of Europe, and it received a great impetus from the Norman conquest. When English law began to settle down into a system, the principle of feudalism was taken as the basis, and it gradually became the undisputed maxim of English law that the sovereign was the supreme lord of all the land and that every one held under him as tenant, that there was no such thing as an absolute private right of property in land, but that the state alone as personified by the sovereign was vested with that right, and conceded to the individual possessor only a strictly defined subordinate right, subject to conditions from time to time enacted by the community (see also FEUDALISM). Feudal tenure was divided into free and non-free. Free tenures were frankalmoign, knight service, serjeanty and free socage. These tenures are dealt with under their separate headings. Base or non-free tenure was tenure in villenage (*q.v.*) and copyhold (*q.v.*), and see also MANOR.

TEPIC, a territory of Mexico facing on the Pacific Ocean and bounded N., E. and S. by Sinaloa, Durango and Jalisco. Area 11,275 sq. m. Pop. (1900) 150,098. The active volcano of Ceboruco rises in the western part of the territory. The slopes and valleys are densely wooded, the lower regions being very fertile and adapted to tropical agriculture. The rainfall is abundant, and the climate hot, damp and malarial. The Rio Grande de Lerma, or Santiago, is the principal river, whose sources are to be found on the high plateau in the state of Mexico. The next largest river is the Mezquital, which has its sources in the state of Durango, not far from the city of that name. The products of the territorial coast lands are sugar, cotton, tobacco, maize, palm oil, coffee, fine woods and medicinal plants. Mining attracts much attention in the sierras, and its mineral deposits are rich. There are cotton and cigarette factories at the town of Tepic, besides sugar works and distilleries on the plantations. The capital of the territory is Tepic (pop. 1900, 15,488), attractively situated on a small plateau 2950 ft. above sea level, 26 m. E. by S. of its port, San Blas, with which it is connected by rail.

The territory of Tepic was detached from the State of Jalisco in 1889 on account of the belligerent attitude of its population, chiefly composed of Indians. A territorial form of government places it more directly under the control of the national executive.

TEPIDARIUM, the term given to the warm (*tepidus*) bathroom of the Roman baths. There is an interesting example at Pompeii; this was covered with a semicircular barrel vault, decorated with reliefs in stucco, and round the room a series of square recesses or niches divided from one another by Telamones. The tepidarium in the Roman thermae was the great central hall round which all the other halls were grouped, and which gave the key to the plans of the thermae: it was probably the hall where the bathers first assembled prior to taking the cold bath or passing through the various hot baths, and was decorated with the richest marbles and mosaics: it received its light through clerestory windows, on the sides, the front and the rear, and would seem to have been the hall in which the finest treasures of art were placed; thus in the thermae of Caracalla, the Farnese Hercules, and the Toro Farnese, the two gladiators, the sarcophagi of green basalt now in the Vatican, and numerous other treasures, were found during the excavations by Paul III. in 1546, and transported to the Vatican and the museum at Naples.

TEPLITZ (Czech, *Teplice*), or TEPLITZ-SCHÖNAU, as it is officially called since the incorporation of the village of Schönau in 1895, a town of Bohemia, Austria, 80 m. N.N.W. of Prague by rail. Pop. (1900) 24,420. It is picturesquely situated in the plain of the Biela, which separates the Erzgebirge from the Bohemian Mittelgebirge, and is a favourite watering-place, containing a large *Kurhaus* and numerous handsome bath-houses. The environs are laid out in pretty and shady gardens and promenades, the finest being in the park which surrounds the château of Prince Clary-Aldringen, built in 1751. The other chief buildings are the Roman Catholic Schlosskirche, built in 1568 and altered to its present form in 1790, the Protestant church, the Jewish synagogue with a conspicuous dome, and the theatre. In the garden of the château are two ancient towers, probably the remains of the Benedictine convent, but ascribed by local tradition to the knight Kolostuj, the legendary discoverer of the springs. The saline-alkaline springs of Teplitz, ten to twelve in number, ranging in temperature from 90° to 117° Fahr., are classed among what are called "indifferent" waters. Used almost exclusively for bathing, they are prescribed for gout, rheumatism, and some scrofulous affections, and their reputed efficacy in alleviating the effects of gun-shot wounds had gained for Teplitz the sobriquet of "the warriors' bath." Military baths are maintained in the town by the governments of Austria, Prussia and Saxony, and there are also bath-houses for the poor. Teplitz is much visited for the after-cure, after Carlsbad and similar spas. The number of patients is about 6000 and the passing visitors about 25,000. The presence of a bed of lignite in the neighbourhood has encouraged the industrial development of Teplitz, which carries on manufactures of machinery and metal goods, cotton and woollen goods, chemicals, hardware, sugar, dyeing and calico-printing.

The thermal springs are fabled to have been discovered as early as 762, but the first authentic mention of the baths occurs in the 16th century. The town is mentioned in the 12th century, when Judith, queen of Ladislaus I. of Bohemia, founded here a convent for Benedictine nuns, which was destroyed in the Hussite wars. In the 17th century Teplitz belonged to the Kinskys, and after Kinsky's murder (25th February 1634) the lordship was granted by Ferdinand II. to Johann Count Aldringen. His sister Anna, who inherited it, married Freiherr Hieronymus von Clary, who assumed the additional name and arms of Aldringen. The family, which was raised to the rank of count in 1666 and of prince of the Empire in 1767, still retains the property. Teplitz figures in the history of Wallenstein, and is also interesting as the spot where the monarchs of Austria, Russia and Prussia first signed the triple alliance against Napoleon in 1813. It is a curious fact that on the day of the earthquake at Lisbon (1st November 1775) the main spring at Teplitz ceased to flow for some minutes.

TERAMO, an episcopal see of the Abruzzi, Italy, the capital of the province of Teramo, 16 m. by rail W.S.W. of Giulianova, a junction on the Ancona-Brindisi railway. Pop. (1901) 10,508 (town); 24,091 (commune). The town stands on the left bank of the Tordino, where it is joined by the Vezzola, at an altitude of 876 ft. above sea-level. The picturesque valley of the Tordino is here dominated by the peaks of the Gran Sasso d'Italia. The town is traversed by one straight wide street with large houses, but for the most part it consists of narrow lanes. The cathedral has a Romanesque Gothic portal of 1332 by a Roman marble worker named Deodatus, and the interior is decorated in the Baroque style, but still retains the pointed vaulting of 1154, introduced into Italy by French Benedictines; it contains a splendid silver antependium by the 15th-century goldsmith Nicolo di Guardiagrele (1433–48). The tower is fine. The church of S. Antonio is also in the Romanesque Gothic style. Under the church of S. Anna dei Pompetti remains of Roman houses and of the original cathedral have been discovered (F. Savini in *Notizie degli scavi*, 1898, 137). In the Communal Gallery is an altarpiece from the cathedral by the Venetian Jacobello del Fiore (1400–1439). The antiquities include remains of a gateway, a theatre and baths, as well as numerous inscriptions. There are manufactures of wool and silk, and of straw hats and pottery.

The ancient Interamna Praetuttiorum (so called to distinguish it from Interamna Lirenas and Interamna Nahars) was the chief town of the tribe of the Praetuttii. Its pre-Roman necropolis was discovered in 1905 (F. Savini in *Notizie degli scavi*, 1905, 267). Of its municipal constitution little is known, indeed in an inscription of the end of the Republic it is spoken of both as a *colonia* and a *municipium*. It was situated on a branch of the Via Caecilia (*q.v.*). Remains of an amphitheatre still exist. In the valley of the Vomano near Montorio was a Roman village, probably dependent on Interamna, with a temple of Hercules (*Corp. inscr. Lat.*, ix. p. 484).

See V. Bindi, *Monumenti degli Abruzzi* (Naples, 1889), 1 sqq.

TERAPHIM (A.V. sometimes transcribes, *e.g.* Judges xvii. 5; xviii. 14 seq.; Hosea iii. 4; sometimes translates "image," 1 Sam. xix. 13; "idols," Zech. x. 2; "idolatry," 1 Sam. xv. 23: R.V. renders consistently "teraphim"), a Hebrew word, found only in the plural, of uncertain etymology. The name appears to be applied to some form of idol (cf. Gen. xxxi. 19 and 30), but details as to its precise configuration, &c., are lacking. From 1 Sam. xix. 13, 16 it would seem that in the early monarchical period a regular place in every household was still reserved for the teraphim; while in the 8th century Hosea (iii. 4) speaks of "ephod and teraphim" as essential elements in the national worship. Later the teraphim with other adjuncts of heathenish worship were banned by the prophets. The meaning of the Elohistic story in Gen. xxxv. 2–4 clearly is that the employment of teraphim and of other heathen practices of Aramean paganism was given up by Israel in order that they might serve Jehovah alone at Bethel. In Judges and Hosea the teraphim are closely associated with the ephod; both are mentioned in connexion with divination (cf. 2 Kings xxiii. 24; Ezek. xxi. 21 [26]; Zech. x. 2). Whether the teraphim were "consulted" by lot or not is uncertain. In view of Ezek. xxi. 21 and Hosea iii. 4 it is difficult to suppose that the teraphim were purely household idols. The Rabbinical conjectures on the subject can be found in Buxtorf, *Lex. Talm.* (ed. Fischer), 1315 seq. One of the most curious is that the teraphim consisted of a mummified human head (see also EPHOD). (W. R. S.; G. H. Bo.)

TERBIUM [symbol Tb, atomic weight 159·2 (O=16)], a metallic chemical element belonging to the rare earth group; it was originally called erbia by its discoverer Mosander (see RARE EARTH). Pure terbium compounds were obtained by G. Urbain (*Compt. rend.*, 1904 seq.) by fractional crystallization of the nickel double nitrates, the ethyl sulphates, and the bismuth double nitrates of the terbium earths. Terbium appears to be trivalent. The oxide is a black or brown powder according as it is prepared from the exalate or sulphate, and when pure it is non-fluorescent, but mixed with gadolinia or alumina it possesses this property. It yields colourless salts; the crystallized sulphate has the formula $Tb_2(SO_4)_3 \cdot 8H_2O$.

TER BORCH (or TERBURG), **GERARD** (1617–1681), Dutch subject painter, was born in 1617 at Zwolle, in the province of Overyssel, Holland. He received an excellent education from his father, also an artist, and developed his talent very early. The inscription on a study of a head proves that Ter Borch was at Amsterdam in 1632, where he studied possibly under C. Duyster or P. Codde. Duyster's influence can be traced in a picture bearing the date 1638, in the Ionides Bequest (Victoria and Albert Museum). In 1634 he studied under Pieter Molyn in Haarlem. A record of this Haarlem period is the "Consultation" (1635) at the Berlin Gallery. In 1635 he was in London, and subsequently he travelled in Germany, France, Spain and Italy. It is certain that he was in Rome in 1641, when he painted the small portraits on copper of "Jan Six" and "A Young Lady" (Six Collection, Amsterdam). In 1648 he was at Münster during the meeting of the congress which ratified the treaty of peace between the Spaniards and the Dutch, and executed his celebrated little picture, painted upon copper, of the assembled plenipotentiaries—a work which, along with the "Guitar Lesson" and a portrait of a "Man Standing," now represents the master in the national collection in London. The picture was bought by the marquess of Hertford at the Demidoff sale for £7280, and presented to the National Gallery by Sir Richard Wallace, at the suggestion of his secretary, Sir John Murray Scott. At this time Ter Borch was invited to visit Madrid, where he received employment and the honour of knighthood from Philip IV., but, in consequence of an intrigue, it is said, he was obliged to return to Holland. He seems to have resided for a time in Haarlem; but he finally settled in Deventer, where he became a member of the town council, as which he appears in the portrait now in the gallery of the Hague. He died at Deventer in 1681.

Ter Borch is excellent as a portrait painter, but still greater as a painter of *genre* subjects. He depicts with admirable truth the life of the wealthy and cultured classes of his time, and his work is free from any touch of the grossness which finds so large a place in Dutch art. His figures are well drawn and expressive in attitude; his colouring is clear and rich, but his best skill lies in his unequalled rendering of texture in draperies, which is seen to advantage in such pictures as the "Letter" in the Dutch royal collection, and in the "Paternal Advice" (known as the "Satin Gown")—engraved by Wille—which exists in various repetitions at Berlin and Amsterdam, and in the Bridgewater Gallery. Ter Borch's works are comparatively rare; only about eighty have been catalogued. Six of these are at the Hermitage, six at the Berlin Museum, five at the Louvre; four at the Dresden Museum, and two at the Wallace Collection.

TERCEIRA, an island in the Atlantic Ocean, belonging to Portugal, and forming part of the Azores archipelago. Pop. (1900) 48,770; area, 224 sq. m. Terceira, *i.e.* "the third," was so called as being the third island of the archipelago to be discovered by the Portuguese. From its central position it was long the seat of administration, but its capital, Angra (*q.v.*) or Angra do Heroismo (pop. 10,788), has lost much of its commercial importance. The other chief towns are Ribeirinha (3090), and Praia da Victoria (3236). Unlike the neighbouring islands, Terceira exhibits few extensive traces of volcanic action; and the summits of its mountains are generally level. It abounds in grain and cattle; but the wines are inferior, and fruits are raised merely for internal consumption. (See also AZORES.)

TEREBINTH, botanical name *Pistacia Terebinthus*, a member of the natural order Anacardiaceae, usually a small tree common in the south of Europe and the whole Mediterranean area. It has a purplish grey bark and compound leaves with two to four pairs, and an odd terminal one, of smooth dark green oval blunt leaflets, which when young are thin, translucent and strongly tinged with reddish purple. The very small numerous unisexual flowers are borne on panicles which spring from just above the scars of last year's leaves. The fruit is a small roundish bright red drupe with a scanty pulp. The plant has been long known in English gardens. A liquid oleo-resinous exudation, known as Chian, Scio or Cyprus turpentine, is obtained by cutting the stem. The Chian turpentine of commerce is obtained exclusively from the island of Scio; the produce is very small, a large tree yielding only 10 or 11 ounces in one year. An allied species, *P. Lentiscus*, is the mastich tree.

TEREDO, a genus of Lamellibranchiate *Mollusca*, of the order Eulamellibranchia, sub-order Adesmacea, family Teredinidae. The animals included in this genus are commonly known as "ship-worms," and are notorious for the destruction which they cause in ships' timbers, the woodwork of harbours, and piles or other wood immersed for a long period in the sea. They inhabit long cylindrical holes, which they excavate in the wood, and usually occur in great numbers, crowded together so that often only a very thin film remains between the adjacent burrows. Each burrow is lined with a layer of calcareous substance secreted by the mollusc; this lining is not usually complete, but stops short a little distance from the inner end of the burrow, where the boring process continues to take place. In some burrows, however, the lining is complete, either because the animal has reached its full size or because some cause prevents it continuing its tunnel; in such cases the calcareous tube has a hemispherical termination. The burrows are usually driven in the direction of the grain of the wood, but not invariably so. When a knot or nail or the tube of a neighbour is reached, the course of the burrow is altered so as to bend round the obstruction. One burrow is never found to break into another.

The adult *Teredo*, when removed from its burrow and calcareous tube, is from a few inches to 3 ft. in length, according to the species to which it belongs, and is cylindrical and worm-like in appearance. The anterior end, which lies at the bottom of the burrow, is somewhat enlarged and bears a pair of shells or valves, which are not connected by the usual ligament, but are widely separated dorsally. The valves are triangular in shape and very concave on the side which is in contact with the animal. In front their edges are widely separated, and the mantle tube, which is elsewhere closed, has here a slight median aperture, through which the short sucker-like foot can be protruded. The next portion of the body behind the shell-bearing part is naked, except for the shelly lining of the burrow, which is secreted by this part. Anteriorly this portion contains part of the body proper; posteriorly it forms a tube divided internally by a horizontal partition into two chambers and representing the two tubular outgrowths of the mantle called siphons, here united together. In the lower chamber are the elongated gill plates, which have the typical lamellibranchiate structure. In the upper chamber anteriorly is the rectum. A thick muscular ring terminates this region of the body, and bears two calcareous plates shaped like spades or battledores. The expanded parts of these plates are free and project backwards; the handle is fixed in a deep socket or pit lined by epidermis. These calcareous plates are called pallets (Fr. *palmules*). Behind the pallets the tubular body bifurcates, forming two siphons similar to those of other Lamellibranchs; the siphons can be contracted or expanded within wide limits of length. The principal organs of the body—stomach, heart, generative organs and nephridia—are situated in the anterior part of the body, forming a visceral mass, which extends some distance behind the valves. The heart is above the intestine and not perforated by it. There are two adductor muscles of which the anterior is rudimentary and situated just above the mouth, while the posterior is large and passes between the middle parts of the shell-valves. The visceral mass extends some distance behind the posterior adductor, and behind the rectum, and the visceral ganglia, which in most Lamellibranchs are attached to the ventral surface of the posterior adductor, are in this case at the end of the visceral mass and at the anterior end of the gills. Besides the visceral ganglia a cerebral and a pedal pair are present. The stomach is provided with a large crystalline style. The function of the pallets is to form an operculum to the calcareous tube when the siphons are withdrawn into it. In some species the external or narrower end of the calcareous tube is provided with transverse laminae projecting into the lumen; and in some the external aperture is divided by a horizontal partition into two, one for each siphon.

The *Teredo* is dioecious, and the males are only in the proportion of 1 : 500 of he females. As in the case of the oyster, the ova are retained in the branchial chamber during the early stages of their development The segmentation of the ovum is unequal, and leads to the formation of a gastrula by epibole. By the growth of a preoral lobe provided with a ring of cilia, and by the formation of a mouth and an anus, the trochosphere stage is reached. A pair of thin shells then appear on the sides of the larva, connected by a hinge on the dorsal median line, and the foot grows out between mouth and anus. By the time the larvae "swarm," or leave the branchial cavity of the parent to live for a time as free-swimming pelagic larvae, the valves of the shell have grown so large as to cover the whole of the body when the velum is retracted; the foot is also long, cylindrical and flexible, and can be protruded far beyond the shell. The valves of the shell at this stage are hemispherical in shape, so that the whole larva when its organs are retracted is contained in a globular case.

Concerning the later changes of the larva and the method by which it bores into wood little or nothing is known from direct observation. Much has been written about the boring of this and other marine animals, but even yet the matter cannot be said to be satisfactorily elucidated. Osler, in a paper in *Phil. Trans.*, 1826, argued that the *Teredo* bores by means of its shells, fixing itself by the surface of the foot, which it uses as a sucker, and then rasping the wood with the rough front edges of the shell-valves. This view was founded on the similarity of the arrangement of the shells and muscles in *Teredo* to those occurring in *Pholas*, in which the method of boring described was actually observed. W. Thompson, in a paper in the *Edinb. New Phil. Journ.*, 1835, supported the view that the excavation is due to the action of a solvent secreted from the surface of the animal. Albany Hancock, again (*Ann. and Mag. Nat. Hist.*, vol. xv.), thinks that the excavating power of *Teredo* is due to silicious particles imbedded in the anterior portion of the integument, in front of the valves. But the actual existence of either silicious particles or acid secretion has been denied by others. Jeffreys believes that the foot is the organ by which the animal burrows. In the larger number of Lamellibranchs the foot is doubtless a burrowing organ, and it is difficult to see how the limpet hollows out the rock to which it is attached if not by means of the surface of its foot. At the same time it is difficult to explain how the soft muscular foot can penetrate into hard wood. The process is of course slow, and Jeffreys supposes that particles are detached one by one from the moistened surface to which the foot is applied. In any case the valves are covered by an epidermis, which could scarcely be there if they were used in burrowing.

Teredo grows and burrows at an extremely rapid rate: spawning takes place in the spring and summer, and before the end of the year the animals are adult and their burrows of large size. Quatrefages relates that at Guipuzcoa (N. Spain) a ferry-boat was sunk accidentally in the spring, and was raised four months afterwards, when its timbers were already rendered useless by *T. pedicellata*. How long the animals live is not accurately known, but Quatrefages found that they nearly all perished in the winter. This cannot be generally the case, as the size of the tubes varies so greatly. In Holland their greatest ravages are made in July and August. Iron ships have nothing to fear from their attacks, and the copper sheathing now almost universally used protects wooden hulls. A great deal of loss is, however, caused by *Teredo* in harbour works and shipping stages, and the embankments in Holland are continually injured by it. The most efficient protection is afforded by large-headed nails driven in in close proximity. Soaking wood in creosote is not a certain safeguard; Jeffreys found at Christiania in 1863 that a large number of harbour piles previously soaked in creosote had been completely destroyed by *T. navalis*. Coal tar and the silicate of lime used for coating stonework have been suggested as protective coverings, but they do not seem to have been adequately tested.

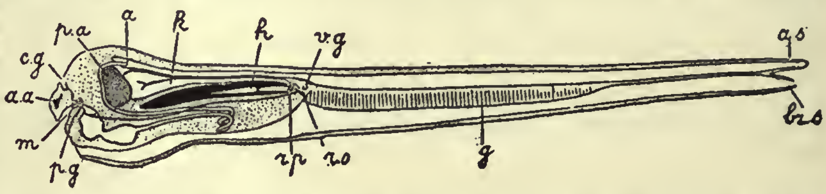

FIG. 1.—Sagittal median section of *Teredo*. *a.*, anus; *a.a.*, anterior adductor muscle; *a.s.*, anal siphon; *br.s.*, branchial siphon; *c.g.*, cerebral ganglion; *g.*, gill; *h.*, heart; *m.*, mouth; *p.a.*, posterior adductor; *p.g.*, pedal ganglion; *r.o.*, renal opening; *r.p.*, reno-pericardial orifice; *v.g.*, visceral ganglion. (Partly after Grobben and Beuck, from Lankester's *Treatise on Zoology*.)

Species of *Teredo* occur in all seas. The animal was known to the ancients and is mentioned by Theophrastus, Pliny and Ovid. In 1715 it is mentioned by Valisnieri, in 1720 by Deslandes. In 1733 great attention was drawn to it on account of the discovery that the wooden dikes of Holland were being rapidly destroyed by ship-worms, and that the country was in danger of inundation. Three treatises were published concerning the animal, by P. Massuet, J. Rousset and Godfrey Sellius. The work of the last-named, which was the best, described the anatomy of the creature and showed that its affinities were with bivalve molluscs. The truth of Sellius's view was not grasped by Linnaeus, who placed *Teredo* together with *Serpula* in the genus *Dentalium*; but its proper position was re-established by Cuvier and Lamarck. Adanson, unaware of the work of Sellius, in 1757 believed himself to be the first to discover the molluscan affinities of *Teredo*. It will not be necessary to give here a definition of the genus taken from any systematist; it will be sufficient to point out that the long cylindrical body with its two small anterior polygonal valves, the absence of a ligament and accessory valves, the muscular ring into which are inserted the calcareous pallets, and the continuous calcareous tube lining the hole bored by the animal are the diagnostic features.

Jeffreys, in his *British Conchology*, gives the following species as British: *Teredo norvegica*, Spengler; *T. navalis*, Linn.; *T. pedicellata*, Quatrefages; *T. megotara*, Hanley. *T. norvegica* occurs chiefly on the west coast of Great Britain. It was taken by Thompson at Portpatrick in Wigtownshire, and occurred in Jeffreys's time in abundance at Milford Haven. This species has been described by Gmelin and a number of British authors as *T. navalis*, Linn. It is distinguished by having the base of the pallets simple, not forked, and the tube semi-concamerated at its narrower posterior end. The length does not usually exceed a foot. It is the *T. navium* of Sellius. *T. navalis* has been identified from the figures of Sellius, to which Linnaeus referred; Sellius called it *T. marina*. It occurs on all the western and southern coasts of Europe, from Christiania to the Black Sea, and is the species which causes so much damage to the Dutch embankments. The pallets of this species are small and forked, and the stalk is cylindrical. The tube is simple and not chambered at its narrow end. *T. pedicellata* was originally discovered by Quatrefages in the Bay of Los Pasages on the north coast of Spain; it has also been found in the Channel Islands, at Toulon, in Provence and in Algeria. In *T. megotara* the tube is simple and the pallets like those of *T. norvegica;* it occurs at Shetland and Wick, and also on the western shore of the Atlantic, where its range extends from Massachusetts to South Carolina. *T. malleolus*, Turton, and *T. bipinnata*, Turton, belong to the West Indies, but are often drifted in floating timber to the coasts of Europe. Other occasional visitants to the British shores are *T. excavata, bipartita, spatha, fusticulus, cucullata*, and *fimbriata*. These were described by Gwyn Jeffreys in *Ann. and Mag. Nat. Hist.*, 1860. *T. fimbriata* is stated to be a native of Vancouver's Island. A kind of ship-worm, the *Nausitora dunlopei* of Perceval Wright, has been discovered in India, 70 m. from the sea, in a stream of perfectly fresh water, namely, the river Kumar, one of the branches of the Ganges. *T. corniformis*, Lam., is found burrowing in the husks of coco-nuts and other woody fruits floating in the tropical seas; its tubes are extremely crooked and contorted for want of space. Fossil wood and palm-fruits of Sheppey and Brabant are pierced in the same way.

Twenty-four fossil species have been recognized in the Lias and succeeding beds of Europe and the United States. The sub-genus *Teredina*, Lam., is a fossil of the Eocene of Great Britain and France.

(J. T. C.)

TEREK, a river of Russian Caucasia. It rises in the Caucasus, on the slopes of Mount Kasbek, in several head-streams, and flows north as far as Vladikavkaz, just above which it emerges from the mountains. Then it flows N.W. and N. as far as approximately 43° 45′ N., whereupon it swings round to the E. and pursues that direction as far as 46° 30′ E. Finally, after a comparatively short run towards the N.N.E., it branches out into a large delta on the west side of the Caspian Sea. This river, the ancient *Alutas*, is at first an impetuous mountain torrent, as are also all its chief tributaries—the Zunzha on the right, and the Ardon, Urukh, Cherek, Urvan, Chegem, Baksan and Malka on the left. All these streams, except the first-named, rise at altitudes of 8000 to 9000 ft. between Mount Kasbek and Mount Elbruz. In its lower course the Terek becomes very sinuous and sluggish, and frequently overflows its banks with disastrous results. Opposite its mouth it forms large sand-banks in the Caspian, and is nowhere navigable. Its length is 300 m., and the area of its drainage basin extends to 22,800 sq. m.

TEREK, a province of Russian Caucasia, situated N. of the Caucasus chain. It is bounded by the government of Stavropol on the N., by the Caspian Sea and Daghestan on the E., by Tiflis and Kutais on the S., and by the Black Sea district and the province of Kuban on the W., and has an area of 23,531 sq. m. From Mount Elbruz to Kasbek the southern boundary coincides with the main range of the Caucasus, and thus includes some of its highest peaks; further east it follows a sinuous line so as to enclose the secondary chains and their ramifications. Nearly one-third of the area is occupied by hilly tracts, the remainder being undulating and flat land belonging to the depression of the Terek; one-half of this last, on the left bank of the river, is occupied by sandy deserts, salt clay steppes, and arid stretches unsuited for cultivation. The Caucasus Mountains are described under that heading. Tertiary formations, overlain by Quaternary deposits, cover a wide area in the prairies and steppes. Mineral springs occur near Pyatigorsk.

The climate is continental. The mean annual temperatures are 49·6° Fahr. at Pyatigorsk (1680 ft. above the sea; January 39°, July 70°) and 47·7° at Vladikavkaz (2345 ft.; January 23°, July 69°), but frosts a few degrees below zero are not uncommon. The mountain slopes receive an abundance of rain (37 in.), but the steppes suffer much from drought (rainfall between 10 and 20 in.). Nearly the whole of the government belongs to the drainage area of the river Terek, but the north-west corner is drained by the upper tributaries of the Kuma. In the lower part of its course the Terek flows at a higher level than that of the neighbouring plains, and is kept in its bed by embankments. Nevertheless inundations are frequent and cause great destruction.

The estimated population in 1906 was 1,044,800. The province is divided into seven districts, the chief towns of which are Vladikavkaz, Groznyi, Kizlyar, Nalchik, Pyatigorsk, Sunzhinsk and Khasavyurt, the last two being nomad centres of administration. Agriculture has developed greatly on the prairies, the area under crops being 9 per cent. of the total. Rye, wheat, oats, barley and potatoes are the principal crops. The vine is very extensively cultivated, especially in the districts of Kizlyar and Pyatigorsk, where 1,500,000 gallons of wine are made annually. Live-stock breeding is widely engaged in, and fishing is an important source of income, especially at the mouth of the Terek. Bees are generally kept, and yield every year nearly half a million sterling worth of honey and wax. Melons, cucumbers and sunflowers are extensively grown. The railway, which formerly stopped at Vladikavkaz, has been continued from the Beslan station, near Vladikavkaz, to Petrovsk on the Caspian Sea, and thence to Baku.

TERENCE. Our knowledge of the life of the celebrated Latin playwright, Publius Terentius Afer, is derived chiefly from a fragment of the lost work of Suetonius, *De viris illustribus*, preserved in the commentary of Donatus, who adds a few words of his own. The prologues to the comedies were among the original sources of Suetonius; but he quotes or refers to the works of various grammarians and antiquaries—Porcius Licinus, Volcacius Sedigitus, Q. Cosconius, Nepos, Santra, Fenestella. There is uncertainty as to both the date of the poet's birth and the manner of his death. His last play was exhibited in 160 B.C., and shortly after its production he went abroad, "when he had not yet completed his twenty-fifth year." Cornelius Nepos is quoted for the statement that he was about the same age as Scipio Africanus the younger (born in 185 or 184 B.C.) and Laelius; while Fenestella, an antiquary of the later Augustan period, represented him as older than either. If Terence was born in 185, he published his six plays between the ages of eighteen and twenty-five. Even in an imitative artist such precocity of talent is remarkable, and the date is therefore open to legitimate doubt.

He is said to have been born in Carthage, and brought to Rome as a slave. At Rome he was educated like a free man in the house of Terentius Lucanus, a senator, by whom he was soon emancipated; whereupon he took his master's *nomen* Terentius, and thenceforward his name was Publius Terentius Afer, of which the last member seems to imply that he was not a Phoenician (*Poenus*) by blood. He was admitted into the intimacy of young men of the best families, such as Scipio, Laelius and Furius Philus; and he enjoyed the favour of older men of literary distinction and official position. In the circle of Scipio he doubtless met the historian Polybius, who was brought to Italy in 167. He is said to have owed the favour of the great as much to his personal gifts and graces as to his literary eminence; and in one of his prologues he declares it to be his ambition, while not offending the many, to please the "boni."

Terence's earliest play was the *Andria*, exhibited in 166 B.C. A pretty, but perhaps apocryphal, story is told of his having read the play, before its exhibition, to Caecilius (who, after the death of Plautus, ranked as the foremost comic poet), and of the generous admiration of it manifested by Caecilius. A similar instance of the recognition of rising genius by a poet whose own day was past is found in the account given of the visit of Accius to the veteran Pacuvius. The next play was the *Hecyra*, first produced in 165, but withdrawn in consequence of its bad reception, and reproduced in 160. The *Heauton Timorumenos* appeared in 163, the *Eunuchus* in 161, the *Phormio* in 161, and the *Adelphoe* in 160 at the funeral games of L. Aemilius Paullus. Of these six plays the *Phormio* and probably the *Hecyra* were drawn from Apollodorus, the rest from Menander. After bringing out these plays Terence sailed from Greek parts, either to escape from the suspicion of publishing the works of others as his own, or from the desire to obtain a more intimate knowledge of that Greek life which had hitherto been known to him only in literature and which it was his professed aim to reproduce in his comedies. The latter is the more probable motive, and we recognize in this the first instance of that impulse to visit the scenes familiar to them through literature which afterwards acted on many of the great writers of Rome. From this voyage Terence never returned. According to one account he was lost at sea, according to another he died at Stymphalus in Arcadia, and according to a third at Leucas, from grief at the loss by shipwreck of his baggage, containing a number of new plays which he had translated from Menander. An old poet quoted by Suetonius states that he was ruined in fortune through his intimacy with his noble friends. Another account speaks of him as having left behind him gardens, to the extent of about twelve acres, close to the Appian Way. It is further stated that his daughter married a Roman knight.

No writer in any literature, who has contented himself with so limited a function, has gained so great a reputation as Terence. He lays no claim to the position of an original artist painting from life or commenting on the results of his own observation. His art has no relation to his own time or to the country in which he lived. The chief source of interest in the fragmentary remains of Naevius, Ennius, Pacuvius, Accius and Lucilius is their relation to the national and moral spirit of the age in which they were written. Plautus, though, like Terence, he takes the first sketch of his plots, scenes and characters, from the Attic stage, is yet a true representative of his time, a genuine Italian, writing before the genius of Italy had learned the restraints of Greek art. The whole aim of Terence was to present a faithful copy of the life, manners, modes of thought and expression which had been drawn from reality a century before his time by the writers of the New Comedy of Athens. The nearest parallel to his literary position may be found in the aim which Virgil puts before himself in his *Bucolics.* He does not seek in that poem to draw Italian peasants from the life, but to bring back the shepherds of Theocritus on Italian scenes. Yet the result obtained by Virgil is different. The charm of his pastorals is the Italian sentiment which pervades them. His shepherds are not the shepherds of Theocritus, nor are they in any sense true to life. The extraordinary result obtained by Terence is that, while he has left no trace in any of his comedies of one sketching from the life by which he was surrounded, there is perhaps no more truthful, natural and delicate delineator of human nature, in its ordinary and more level moods, within the whole range of classical literature. His permanent position in literature is due, no doubt, to the art and genius of Menander, whose creations he has perpetuated, as a fine engraver may perpetuate the spirit of a great painter whose works have perished. But no mere copyist or verbal translator could have attained that result. Though without claims to creative originality, Terence must have had not only critical genius, to enable him fully to appreciate and identify himself with his originals, but artistic genius of a high and pure type. The importance of his position in Roman literature consists in this, that he was the first writer who set before himself a high ideal of artistic perfection, and was the first to realize that perfection in style, form, and consistency of conception and execution. Living in the interval between Ennius and Lucilius, whose original force and genius survive only in rude and inartistic fragments, he produced six plays, which have not only reached our time in the form in which they were given to the world, but have been read in the most critical and exacting literary epochs, and still may be read without any feeling of the need of making allowance for the rudeness of a new and undeveloped art.

While his great gift to Roman literature is that he first made it artistic, that he imparted to "rude Latium" the sense of elegance, consistency and moderation, his gift to the world is that through him it possesses a living image of the Greek society in the 3rd century B.C., presented in the purest Latin idiom. Yet Terence had no affinity by birth either with the Greek race or with the people of Latium. He was more distinctly a foreigner than any of the great classical writers of Rome. He lived at the meeting-point of three distinct civilizations—the mature, or rather decaying, civilization of Greece, of which Athens was still the centre; that of Carthage, which was so soon to pass away and leave scarcely any vestige of itself; and the nascent civilization of Italy, in which all other modes were soon to be absorbed. Terence was by birth an African, and was thus perhaps a fitter medium of connexion between the genius of Greece and that of Italy than if he had been a pure Greek or a pure Italian; just as in modern times the Jewish type of genius is sometimes found more detached from national peculiarities, and thus more capable of reproducing a cosmopolitan type of character than the genius of men belonging to other races.

The prologues to Terence's plays are of high interest. Their tone is for the most part apologetic, and indicates a great sensitiveness to criticism. He constantly speaks of the malevolence and detraction of an older poet, whose name is said to have been Luscius Lavinius or Lanuvinus. The chief charge which his detractor brings against him is that of *contaminatio*, the combining in one play of scenes out of different Greek plays. Terence justifies this practice by that of the older poets, Naevius, Plautus, Ennius, whose careless freedom he follows in preference to the "obscura diligentia" of his detractor. He recriminates upon his adversary as one who, by his close adherence to his original, had turned good Greek plays into bad Latin ones. He clears himself of the charge of plagiarizing from Plautus and Naevius. In another prologue he contrasts his own treatment of his subjects with the sensational extravagance of others. He meets the charge of receiving assistance in the composition of his plays by claiming as a great honour the favour which he enjoyed with those who were the favourites of the Roman people. But the gossip, not discouraged by Terence, lived and throve; it crops up in Cicero and Quintilian, and the ascription of the plays to Scipio had the honour to be accepted by Montaigne and rejected by Diderot.

We learn from these prologues that the best Roman literature was ceasing to be popular, and had come to rely on the patronage of the great. A consequence of this change of circumstances was that comedy was no longer national in character and sentiment, but had become imitative and artistic. The life which Terence represents is that of the well-to-do citizen class whose interests are commonplace, but whose modes of thought and speech are refined, humane and intelligent. His characters are finely delineated and discriminated rather than, like those of Plautus, boldly conceived. Delicate irony and pointed epigram take the place of broad humour. Love, in the form of pathetic sentiment rather than of irregular passion, is the chief motive of his pieces. His great characteristics are humanity and urbanity, and to this may be attributed the attraction which he had for the two chief representatives of these qualities in Roman literature—Cicero and Horace.

Terence's pre-eminence in art was recognized in the Augustan age; and Horace expresses this opinion, though not as his own, in these words (Epistles II. i. 59):—

"Vincere Caecilius gravitate, Terentius arte."

The art of his comedies consists in the clearness and simplicity with which the situation is presented and developed, and in the consistency and moderation with which his various characters play their parts. But his greatest attraction to both ancient and modern writers has been the purity and charm of his style. He makes no claim to the creative exuberance of Plautus, but he is entirely free from his extravagance and mannerisms. The superiority of his style over that of Lucilius, who wrote his satires a generation later, is immeasurable. The best judges and the greatest masters of style in the best period of Roman literature were his chief admirers in ancient times. Cicero frequently reproduces his expressions, applies passages in his plays to his own circumstances, and refers to his personages as typical representations of character.[1] Julius Caesar's lines on Terence, the "dimidiatus Menander," while they complain of lack of comic power, characterize him as "puri sermonis amator." Horace, so depreciatory in general of the older literature, shows his appreciation of Terence by the frequent reproduction in his *Satires* and *Odes* of his language and his philosophy of life. Quintilian applies to his writings the word *elegantissima*. His works were studied and learned by heart by the great Latin writers of the Renaissance, such as Erasmus and Melanchthon; and Casaubon, in his anxiety that his son should write a pure Latin style, inculcates on him the constant study of Terence. Montaigne[2] applies to him the phrase of Horace: "Liquidus puroque simillimus amni." He speaks of "his fine expression, elegancy and quaintness," and adds, "he does so possess the soul with his graces that we forget those of his fable." Sainte-Beuve devotes to him two papers of delicate and admiring criticism. He quotes Fénelon and Addison, "deux esprits polis et doux, de la même famille littéraire," as expressing their admiration for the inimitable beauty and naturalness of one of his scenes. Fénelon is said to have preferred him even to Molière. Sainte-Beuve calls Terence the bond of union between Roman urbanity and the Atticism of the Greeks, and adds that it was in the 17th century, when French literature was most truly Attic, that he was most appreciated. M. Joubert[3] applies to him the words, "Le miel attique est sur ses lèvres; on croirait aisément qu'il naquit sur le mont Hymette."

The chief manuscript of Terence is the famous *Codex Bembinus*, of the 4th or 5th century, in the Vatican. Another Vatican MS. of the 10th century contains illustrations based on an old tradition. Each play has an argument in metre by Sulpicius Apollinaris (2nd century of our era). We have also a valuable commentary (newly edited by P. Wessner) on five of the plays, derived chiefly from Euanthius and Donatus (both of the 4th century), and another of less importance by one Eugraphius.

The *editio princeps* was published at Strassburg in 1470. The most famous edition is that of Bentley, published at Cambridge in 1726. At present the best texts are those by K. Dziatzko (Leipzig, 1884), and A. Fleckeisen (Teubner, 2nd ed., 1898). Each of the plays has recently been edited with English notes.

For a conspectus of Terentian studies see Teuffel-Schwabe-Warr, *History of Roman Literature*, and Schanz's *Geschichte der römischen Litteratur* (3rd ed., 1907). Among critical estimates of Terence may be mentioned Sainte-Beuve's in *Nouveaux lundis* (3rd and 10th of August 1863), and Mommsen's in the *History of Rome*, book iv., chapter xiii.

Molière made large use of the *Phormio* in *Les Fourberies de scapin*, and the subject of *l'École des maris* is taken from the *Adelphoe*. Terence was translated into English verse by George Colman (1765). (W. Y. S.; E. H.*)

TERENTIANUS, surnamed MAURUS (a native of Mauretania), Latin grammarian and writer on prosody, flourished probably at the end of the 2nd century A.D. His references to Septimius Serenus and Alfius Avitus, who belonged to the school of "new poets" (*poetae neoterici* or *novelli*) of the reign of Hadrian and later, seem to show that he was a near contemporary of those writers. He was the author of a treatise (incomplete) in four books (written chiefly in hexameters), on letters, syllables, feet and metres, of which considerable use was made by later writers on similar subjects. The most important part of it is that which deals with metres, based on the work of Caesius Bassus, the friend of Persius. By some authorities Terentianus has been identified with the prefect of Syene mentioned in Martial (i. 86), which would make his date about a century earlier; others, again, who placed Petronius at the end of the 3rd century (a date no longer held), assigned Terentianus to the same period, from his frequent references to that author.

Best edition, by H. Keil, *Grammatici Latini*, vi.; with commentary by L. Santen (1825); see also Teuffel-Schwabe, *Hist. of Roman Literature* (Eng. tr.), 373*a*.

TERGESTE (mod. *Trieste*, *q.v.*), an ancient city of Istria, 26 m. by road E.S.E. of Aquileia, at the northern extremity of the peninsula of Istria, in a bay at the head of the Adriatic Sea. Its importance was in ancient days, as now, mainly due to its commerce as the outlet of Pannonia and Dalmatia. It is first mentioned about 100 B.C. as a village. In 52 B.C. it was attacked by barbarian tribes from the interior. In 33 B.C. Augustus during his Dalmatian wars built a wall and towers there, as an inscription records; in a medieval copy of it the emperor Frederick III. mentions his own restoration of the city walls for the fourth time in 1470. At this time it probably became a colony, as it certainly was in Pliny's days. It appears to have had an extensive territory assigned to it. The loftily situated cathedral of S. Giusto occupies the site of a Roman temple, some of the walls and columns of which may be seen in the tower Into the façade are built fragments of sepulchral reliefs. The church itself has a curious plan which is due to its having been formed out of two distinct churches standing side by side, which were united in the 14th century. Each of these is a basilica with ancient columns and mosaics in the apse. The southern church, S. Giusto, has a central dome. The so-called Arco di Riccardo is a half-buried Roman arch with Corinthian pilasters, possibly a triumphal arch, possibly connected with an aqueduct.

The museum contains inscriptions, mosaic pavements, &c., from the ancient town, of which no remains beyond those mentioned now exist above ground.

See Th. Mommsen in *Corp. inscr. Latin.* V. (1883), p. 53 sqq.; T. G. Jackson, *Dalmatia, Istria and the Quarnero* (Oxford, 1887), III., 343; G. Caprini, *Trieste* (Bergamo, 1906). (T. As.)

TERLIZZI, a town in Apulia, Italy, in the province of Bari, and 18 m. by steam tramway W. from that town, situated in the midst of a fertile plain, 627 ft. above sea-level. Pop. (1901) 23,394. It has a castle which at one time was very strong, and occasionally resorted to by the Emperor Frederick II. and afterwards by the Aragonese sovereigns. The walls and towers of the town remain, but the fosse has been turned into boulevards. Terlizzi has some trade in the wine and fruit of the district. Near it, in an ancient tomb, was found in 1745 a fine inkstand inlaid in silver.

TERM, an English word which has various meanings, all arising from its etymology (Lat. *terminus*), and the idea of limiting or defining.

A *term of years*, in English law, is the time during which an interest in an estate for life or for years is enjoyed, also the interest itself, because such an interest must determine at a definite time. If the interest be for life, it is an estate of freehold; if for years, only a personal interest in real estate, and so personalty, even though the length of the term—for instance, 1000 years—may far exceed in duration any possible life estate. A term of years is of two kinds—the first that created by an ordinary lease reserving a rent, as of a house or a building lease; the second that created by a settlement or a will, usually without rent reserved, for the purpose of securing payment of money, such as portions to younger children, by the owner of the land. Both kinds have been considerably affected by the Conveyancing Acts of 1881 and 1882, which enable a mortgagor or mortgagee in possession to make certain leases. Before 1845 provision was always made in conveyances for keeping on foot a term to attend the inheritance, as it was called—that is, for assigning the remainder of a term to trustees for the protection of the owner of the property against rent-charges or other incumbrances created subsequently to the term,

[3] Quoted by E. Negrette in his *Histoire de la littérature latine*.

although the term had been satisfied—that is, the purpose for which the term has been created had been fulfilled. By the Assignment of Satisfied Terms Act 1845 the assignment of satisfied terms was rendered unnecessary. The Conveyancing Acts 1881 and 1882 give power to enlarge the unexpired residue of a long term in certain cases into the fee simple.

Terms, in the sense of a limited and certain period of time during which the law courts are open, used to affect only what were called in England the superior courts—that is, the king's bench, common pleas and exchequer. They were originally the leisure seasons of the year which were not occupied by great feasts or fasts of the Church or by agriculture. Their origin is no doubt to be traced back to the legislation of the early Christian emperors, the principle being adopted in England through the influence of ecclesiastical judges. Terms were regulated by many acts of parliament, the effect of which was to confine to a comparatively short period the time during which the courts could sit *in banco*—that is, for the decision of questions of law as distinguished from the decision of questions of fact. There were four terms, Hilary, Easter, Trinity and Michaelmas, the average duration of each being about three weeks. All legislation on the subject previous to 1873 is now merely of historical interest, for by the Judicature Act of that year terms were abolished so far as related to the administration of justice and sittings substituted. The previous subdivisions of the legal year were, however, retained, the dates of commencement and termination being somewhat changed. The Michaelmas sittings of the high court and court of appeal are now held from the 24th of October to the 21st of December, the Hilary sittings from the 11th of January to the Wednesday before Easter, the Easter sittings from the Tuesday after Easter week to the Friday before Whitsunday, and the Trinity sittings from the Tuesday after Whitsun week to the 12th of August, all dates inclusive. The old terms, with their duration as fixed by statute, are now kept alive only for the purpose of reference in all cases in which they are used as a measure of time. In the United States the terms or sittings of the courts are not limited to any fixed period of time, but vary according to the judges available and the amount of judicial business which is likely to come before the courts. The dining-terms at the Inns of Court also correspond in point of time with the old terms and not with the sittings.

In universities and schools the word *term* is used for the period during which instruction is given to the students or pupils. University and school terms differ from law terms and from each other both in period and duration. At the university of Cambridge the academic year is divided into three terms, Michaelmas, Lent and Easter; while at the university of Oxford there are four terms in the year, Michaelmas, Hilary, Easter and Trinity. School years now generally consist of three terms, divided by Christmas, Easter and Summer holidays, the old half-years having gradually been abolished. In higher educational institutions in the United States the university or college year is generally divided into three terms called either the Fall, Winter and Spring terms, or much less frequently the first, second and third terms. In some institutions, however, the so-called semester system has been adopted, the year being divided into two terms, so far as instruction is concerned, though even in these cases vacations at Christmas time and in the early spring divide the year into three parts, which are sometimes, though not in the usual or proper sense, called terms.

In Scotland terms are the days at which rent or interest is payable. They are either legal or conventional: the legal are Whitsunday and Martinmas; the conventional are fixed by agreement between the parties. Terms as times of court sittings were defined by 6 Anne c. 53, which fixed four terms—Martinmas, Candlemas, Whitsuntide and Lammas—for the now obsolete court of exchequer, to which the winter and summer sittings of the court of session now correspond.

TERMINAL FIGURES, also called "termini" or "terms," in architecture, figures of which the upper parts only, or perhaps the head and shoulders alone, are carved, the rest running into a parallelopiped, and sometimes into a diminishing pedestal, with feet indicated below, or even without them (see HERMAE).

TERMINATOR (from the Latin *terminare*, to limit), in astronomy, the bounding line beween light and darkness on the apparent disk of the moon or of a planet.

TERMINI IMERESE (anc. *Thermae Himeraeae*), a seaport town of Sicily, in the province of Palermo, 23 m. E.S.E. of it by rail. Pop. (1901) 20,633. It is finely situated on a promontory above its harbour, and it is possible that it was occupied by an early Phoenician settlement; as a town, however, it was not founded until 407 B.C. by the Carthaginians, after their destruction of Himera, in the vicinity of hot springs mentioned by Pindar (*Od.* xii. 19) which are still resorted to and are well fitted up (temp. 110° F.). It remained a Carthaginian colony, though thoroughly Greek[1] in character, until it was taken by Rome in the First Punic war. In the time of Cicero it was flourishing, though not of great importance. Augustus sent a Roman colony to it, and a Roman road ran from it to Catana. Its medieval castle was destroyed in 1860. The modern town presents no features of interest; there is a collection of antiquities and pictures, with a considerable number of Roman inscriptions. Scanty remains of buildings of Roman times (an amphitheatre and a so-called basilica) exist in the upper part of the town; and outside it on the S. are considerable remains of two aqueducts of the same period crossing a deep ravine. The surrounding district is fertile.

Four m. E. of Termini, about 1 m. W. of the railway station of Cerda, on an E. spur of the Monte S. Calogera, called Monte Castellaccio, is a Cyclopean wall, about 66 ft. long, 10 ft. thick, and 30 ft. high in the middle, blocking the only access to the summit of the spur, on the N.E. Fortifications in this style are very rare in Sicily.

See B. Romano, *Antichità Termitane* (Palermo, 1838); Mauceri, *Acropoli Pelasgica nei dintorni di Termini Imerese* (Palermo, 1896).
(T. As.)

TERMINUS, in Roman mythology, the god of boundaries, the protector of the limits both of private property and of the public territory of Rome. He was represented by a stone or post, set up in the ground with the following religious ceremonies. A trench was dug, in which a fire was lighted; a victim was sacrificed, and its blood poured into the trench; the body, upon which incense and fruits, honey and wine were thrown, was then cast into the fire. When it was entirely consumed, the boundary stone, which had been previously anointed and crowned with garlands, was placed upon the hot ashes and fixed in the ground. Any one who removed a boundary stone was accursed (*sacer*) and might be slain with impunity; a fine was afterwards substituted for the death penalty. On the 23rd of February (the end of the old Roman year) the festival called Terminalia, according to Wissowa a festival not of the god but of the boundary stones (*termini*), was held. The owners of adjacent lands assembled at the common boundary stone, and crowned their own side of the stone with garlands; an altar was set up and offerings of cakes, corn, honey and wine were made (later, a lamb or a sucking pig was sacrificed). The proceedings closed with songs to the god and a general merry-making, in which all the members of the family and the servants took part. A similar festival was also held at the old boundary of the Roman territory between the fifth and sixth milestones on the road to Laurentum. The custom of fixing the boundaries of property and the institution of the yearly festival were both ascribed to Numa. Another Sabine prince, Titus Tatius, had dedicated a stone to Terminus on the Capitoline hill. When Tarquinius Superbus desired to build a temple to Jupiter, the auguries forbade its removal, and it was enclosed within the walls of the new sanctuary, an indication of the immovability of such stones and of the permanence of the Roman territory. Terminus was probably in its origin only an epithet of Jupiter. The fact of the inclusion of his statue in the temple of Jupiter Capitolinus; the hole cut in the temple roof so that he might be worshipped in the open air as being, like Jupiter, a god of

[1] Agathocles was a native of Thermae.

the sky; and the later assumption of a Jupiter Terminus or Terminalis (cf. the Greek Ζεὺς ὅριος) support this view.

See Dion. Halic. ii. 74; Plutarch, *Numa*, 16, *Quaest. Rom.*, 15; Livy i. 55; Horace, *Epodes*, ii. 59; Ovid, *Fasti*, ii. 637, 677; Siculus Flaccus in *Gromatici veteres*, ed. Lachmann (1848); G. Wissowa, *Religion und Kultus der Römer* (1902); W. W. Fowler, *The Roman Festivals* (1899); G. Jourde, *Le Culte du dieu Terme* (Paris, 1886).

TERMITE, the name applied to a group of insects with four wings which are developed outside the body (a large proportion of the individuals become adult, however, without wings appearing at all). The wings are of nearly one size, of long, narrow form, of paper-like consistence, and in repose are placed flat on the back of the insect so that only one wing shows. After a short time the wings are shed, and only small stumps remain as evidence of the individual being a winged form. The mouth has strong mandibles. Formerly termites were classed as a part of the order Neuroptera, but more recently they have been separated by certain zoologists from the true Neuroptera, and associated with some other forms as an order Corrodentia. By Packard they have been associated with Mallophaga, and called Platyptera. They now constitute with the Embiidæ—a small and obscure family—the order Isoptera, of which about 300 species are known. Termites are more widely known as white ants, but as they are extremely different from true ants, and as they are rarely white, this designation is very deceptive, and should be abandoned.

Termites are found only in warm climates, where they are sometimes very destructive. They are vegetarian, but occasionally eat, or destroy, dry animal matter. The basis of their alimentary regimen is woody matter. Some of them make use of fungi growing in their abodes as food; some cut and store grass; others prepare a peculiar kind of food, which is stored in a tough, dry form, so that it has to be moistened before it can be eaten. Termites are social insects; many of them construct large edifices called termitaria and often spoken of as nests. A termitarium frequently contains an enormous number of individuals forming the society or colony. Termites are totally different in structure and development from all other social insects, but their social existence exhibits numerous analogies with that of the ants and other social Hymenoptera. The most remarkable of these analogies is that the reproduction of the species in each community is confined to a single pair, or to a very limited number of individuals. The members of one society or colony, however numerous or dissimilar they may be, are the descendants of a single pair. The colony is—so far as is known, and on this, as well as on many other points, authentic information is scanty—first started by a pair of winged individuals that cast their wings, secrete themselves in a suitable place, and produce young; the colony, however huge, being subsequently developed by the extreme fertility of the reproductive pair. Very little is known as to how long a colony endures, and, as there is great variety in the social conditions of different kinds of termites, it is probable that there is considerable difference as to the point in question. As a rule a family or colony has only a single termitarium, but there are cases in which a single family has several separate abodes, though usually only one of them is a real home containing reproductive individuals. The social life in termites, as well as in all other social insects, is clearly a development of the family life. It is accompanied by extraordinary modifications of the forms of the individuals constituting the society, and by a great division of labour. As regards the forms, or castes, termites differ totally from other social insects; in the latter case there are great differences between the males and females, and the whole of the castes are of the female sex, whereas in termites the males and females are extremely similar, and the castes are in no way correlative with sex. As the termite life is a family life, and as there is normally only a single pair of reproductive individuals in each community, it is easily comprehensible that if anything goes wrong with this pair, the community is at once thrown into a state of complete disorganization. But this misfortune is mitigated by a method which termites have of keeping individuals in an undifferentiated state, and of turning some of them speedily into reproductive individuals, whereby the community is restored to something like a natural condition of activity and growth.

Apart from the forms that are merely juvenile, the following kinds of adults are normally present in a colony: (1) workers, (2) soldiers, (3) winged individuals ready to leave the nest, (4) king and queen.

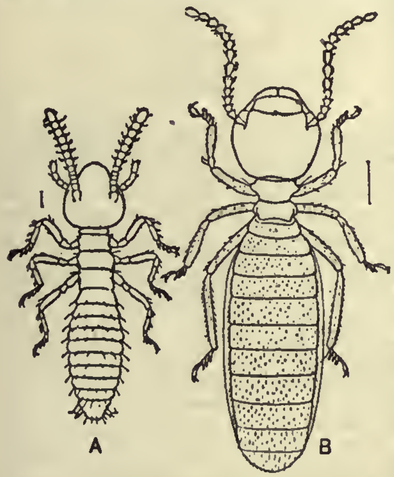

Fig. 1.—A, newly hatched termite; B, worker termite; *Termes nemorosus*.

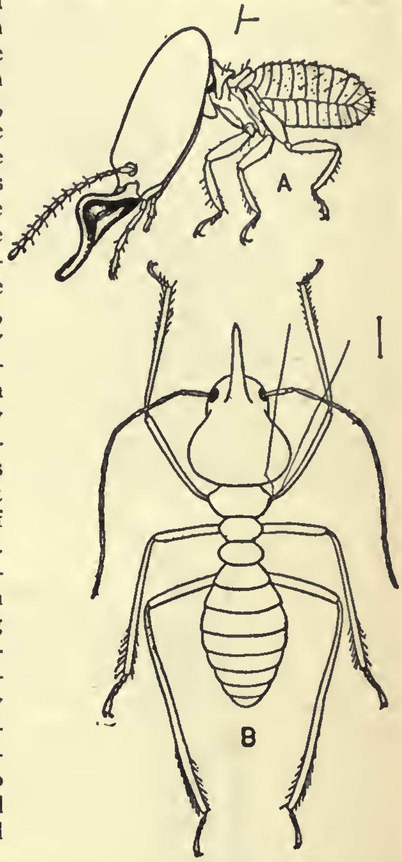

Fig. 2.—A, mandibulate soldier of *Termes nemorosus*; B, nasute soldier of *T. hospitalis*.

(1) The *worker* termite resembles the young in general appearance, and, like the young, has no trace of wings (fig. 1). The two segments behind the head are more contracted, so that head, thorax and abdomen are more differentiated than they are in the young. The colour too is different, the young being milky-white, whereas the adult worker is variously pigmented according to its species, but is never milky-white. The worker is generally blind, and in only a few species does it possess rudimentary eyes. The species of the group *Calotermitides* have no workers. In the other species the workers look after the eggs and young, and perform most, if not all, of the industrial work of the community. They are also, in some cases, effective combatants, though quite destitute of any special structures to suit them for this purpose. The sexual organs do not undergo development, but it has been satisfactorily ascertained that both sexes are represented amongst the workers. In certain species the workers seem to be dimorphic, so far as size is concerned, but this point has apparently been only very inadequately considered. Workers form a very large but variable proportion of the members of a community.

(2) The *soldier* termite is the most extraordinary feature of termite biology It is more varied than any of the other castes, so that most of the species of termites can be best distinguished by their soldiers. The chief feature of the soldier is an extraordinary development of the head, or of the head and mandibles. There are two very distinct kinds of soldiers: (*a*) the flat-headed or mandibulate soldier, and (*b*) the nasute or rostrate soldier (fig. 2). In the first kind the head is usually developed out of all proportion to the rest of the body; the mandibles are frequently enormous, and, being in many cases asymmetric, give the appearance of deformity. In the nasute soldier the head is thick or convex, and may be described as unicorn—that is to say, it is prolonged in the middle so as to form a single pointed horn; the mandibles are never largely developed. No species of termite has both mandibulate and nasute soldiers, although the reverse is sometimes still

stated in books. The soldiers of some species are, however, dimorphic to the extent that larger and smaller forms occur in the same nest without intermediates. In other cases soldiers of simply variable size exist. The soldier is blind and wingless, though in a few soldiers minute wing-rudiments can be detected. As in the worker, the development of the sex organs is arrested, but both sexes are represented. The function of the soldiers is probably, as stated by Haviland, defence. The mandibulate soldiers use their heads as blocks to stop gaps in the nests, and employ terrifying but somewhat theatrical devices, making threatening motions and producing noises by movements of the head and thorax. The nasute soldiers emit a fluid from the tip of the rostrum, and dab it upon their enemies with some skill. Soldiers are present in all species of termites except the South American genus *Anoplotermes*. It is a remarkable fact that in the group *Calotermitides* soldiers exist although there are no workers, but in this case the function of the soldier seems to be very much that of a worker. Grassi says that in *Calotermes flavicollis* all the individuals of a community work for the common welfare. Moreover, in the *Calotermitides* no very great development of the heads or mandibles occurs.

(3) *Adult or Winged Termite.*—Such of the young as do not become workers or soldiers grow and develop after the fashion usual in exopterygote insects. Moults take place, the wing-pads gradually increase in size, eyes appear, and finally pigmentation takes place, and the winged insect is perfected at the last moult (fig. 3). In prosperous colonies these winged insects are produced in large numbers and emerge at intervals as swarms. They have extremely feeble powers of flight, and apparently scarcely any other capability. They are a favourite food of a large number of animals, including even man. They have well-developed eyes and ocelli, and differ from all the other forms by their greater pigmentation. The function of these adults is to diffuse the species, and to favour crossing outside the family circle. Attainment of this second end is, in some cases, favoured by the fact that the whole of the individuals constituting a swarm consist of one sex only. This extraordinary fact is attested by Grassi, but has not yet received the attention it merits. If a termite colony be compared with a tree or plant, the winged forms, it is clear, functionally correspond to the flowers and seeds of the tree; indeed, Fritz Müller and Grassi go further, and conclude that the modes of diffusion and reproduction of termites are analogous to the modes of plants of continuing the species by means of cleistogamic as well as ordinary flowers. The force of this comparison will be better appreciated after the reader has made himself acquainted with the facts connected with the neoteinic forms of termites.

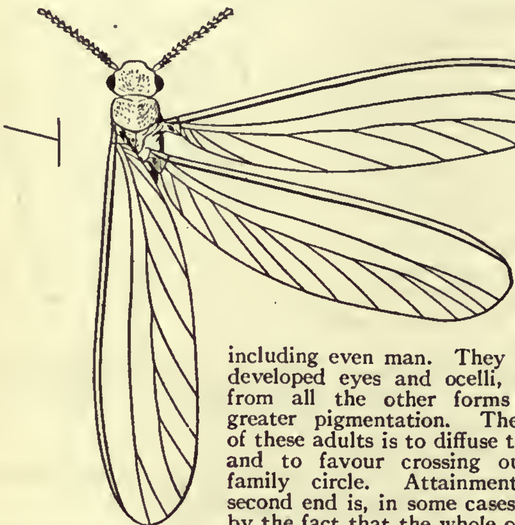

FIG. 3.—Adult Winged Termite: *T. nemorosus;* wings of the right-hand side expanded.

(4) *King and Queen.*—As a rule each community includes only a single pair of individuals apt for reproduction; these are the royal pair, or king and queen (fig. 4). They are adult termites that have shed the wings they formerly possessed. The queen usually undergoes an extraordinary increase in the size of the abdomen, which may be distended to many hundred times its original capacity (fig. 4, A). In many species the king and queen are confined in a royal cell, out of which they cannot move, though the workers, owing to their smaller size, can get in and out to tend them. In other cases the queen only is so imprisoned, the king being able to leave the cell. In still other cases neither king nor queen is effectually imprisoned. Much discrepancy of opinion exists as to the invariable presence of a king in each nest; this, however, is explained by Haviland's observation that the king is active and timid, and when a nest is opened seeks safety by running away and concealing himself, so that he is sometimes only discovered when the very last fragment of the nest is brought under scrutiny. Another point on which extremely diverse opinions are expressed is the copula of the sexes. It is usually stated that the swarming of termites is analogous to that of bees and ants, in which groups of insects the conjunction of the sexes takes place at this period, and at this period only. In the termites the reverse is the case. The swarming is not at all a nuptial flight; indeed, at that time the sexes are not apt for reproduction. Copulation only takes place after a pair have cast their wings and have established themselves together. It is repeated at intervals, and is thus quite dissimilar from the corresponding phenomenon in Hymenoptera. The male has no intromittent organs, so that copula during flight is impossible. Grassi has actually witnessed the act in subsequent life. Haviland is of opinion that in some cases the male fertilizes the eggs without connexion with the female.

(5) *Neoteinic and Substitution Forms.*—When a colony of termites is deprived of king and queen it can replace them by forms specially prepared. These substitution forms are of two kinds—(*a*) normal adult individuals, and (*b*) neoteinic forms. The latter may be described as unnatural kings and queens possessing reproductive powers, though the wings have never been developed and some other parts of the body have not taken on the fully adult state. Haviland removed the royal pairs from nests of *Termes malayanus*, and after three or four months again examined the nests: in three out of the five cases substitution pairs exactly resembling the original ones, with well-formed wing-stumps, were present; in the other two cases he failed to find the royal cell, and believes that the loss had not been repaired. In other species the bereavement is made good by means of neoteinic instead of normal individuals, and in certain species neoteinic forms are abundantly found. In the case of substitution forms there is usually more than one pair present in a colony, and sometimes numerous pairs exist. Grassi says that in Sicily the colonies of *Termes lucifugus* are kept up entirely by neoteinic kings and queens; in other words, the swarms are nearly or quite useless. The neoteinic forms are compared to cleistogamous flowers; and this curious case is parallel with that of a species of plant whose reproduction should be accomplished entirely by its cleistogamous flowers, though at the same time it produced perfect flowers in abundance. The condition recorded by Grassi is probably extremely exceptional. Fritz Müller found once a colony in which a true king was acting as consort to a considerable number of neoteinic queens, no true queen being present.

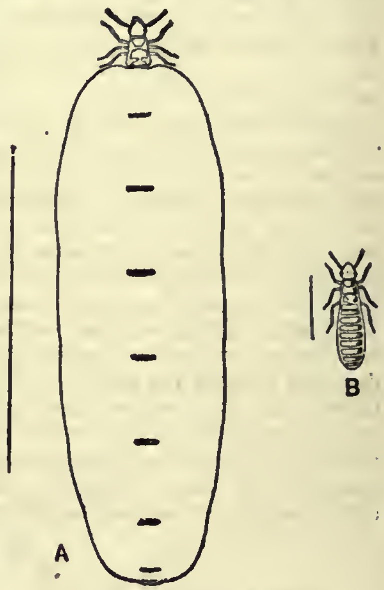

FIG. 4.—A, queen; B, king: *T. nemorosus.*

In order to understand the curious phenomena presented by the castes and variety of forms of a single species of termite, it is necessary to become acquainted with their food habits, which are very peculiar and may be described as communistic. Termites have the habit of eating their cast skins and even their dead companions, and in fact their system of keeping the nest clean seems to be that of eating the refuse of their own bodies till it no longer contains any digestible matter. This cannibalism is the more remarkable, as they will not eat other termites. The most curious part of their dietary is their complex system of feeding from the matters contained in the alimentary systems of their fellows. When a termite wishes food it strokes the body of another individual with its antennae, and the specimen thus caressed exudes from the posterior or from the anterior part of the body a drop of matter, which is eaten by the hungry one. The matter exuded from the posterior part of the body appears to be very different from that yielded by the mouth, so that there are at least two kinds of this excretory food. The proctodaeal food (that which comes from the posterior part of the body) is in great favour with adult termites, but so far as is known it is not used for feeding the newly born young, which are believed to be fed on matter elaborated in the bodies of the adult workers and communicated by their mouths. Subsequently the young take also proctodaeal food, and triturated vegetable matter.

Origin of the Castes.—When termites are hatched from the eggs none of the remarkable differences that are manifested in the individuals in subsequent life can be detected. The sexes are in termites extremely similar in external characters. When the young are hatched they all appear nearly exactly alike, though on careful examination the sexes can be distinguished.

But no other difference than that of sex can be detected. In the article ANT in the ninth edition of the *Encyclopaedia Britannica* it was stated that "the distinction between soldier and worker can be easily seen in the egg." This is contradicted by all modern observations, and is certainly erroneous. It is true that considerable difference of opinion exists as to when the distinction between soldier and worker first becomes evident, but all are agreed that it is not till after the growth is to some extent accomplished. The discrepancy that exists in opinions on this point is due to the facts: (1) that different species have been under observation; and (2) that the modification of the larva to form a soldier may begin at more than one period of the development even in the same species. It being ascertained that all termites begin as undifferentiated larvae, the question arises as to what causes the differentiation into castes. This question is the more important as two of the castes (the worker and soldier) do not at all resemble their parents. Grassi, from an examination of the individuals of a large number of nests of *Termes lucifugus*, arrived at the conclusion that all start as undifferentiated larvae, and that the regular development of *Termes* up to the perfect insect may undergo a deviation at various periods of life leading to the formation of workers, of neoteinic forms, or of soldiers, the last passing through the stage of the young worker. He attributes this deviation, which may take place at various periods, to the influence of food, and attaches special importance to the salivary food. The soldiers have no wings; nevertheless a larva, or young nymph that has the rudiments of wings, can be made into a soldier. Grassi has found juvenile specimens that have already assumed the soldier form, although they possess the rudiments of wings. It appears from his observations that the worker may be considered as a form with arrested development, and the soldier as a form with arrested and much diverted development, while the neoteinic forms are individuals in which the reproductive organs are perfectly developed, while some of the bodily structures have suffered arrest of development and even some amount of atrophy.

FIG. 5.—Termitarium of *Termes malayanus: f*, fungus-chamber; *c*, royal cell.

The soldier form of termite presents most difficult questions to the biologist, its special structures bearing no approximation to any characters possessed by the parents. Various theories have been proposed to account for this fact, but they are mere guesses. We may, however, mention that it is possible that soldiers and workers occasionally produce young. This has never been actually observed, but specimens have been found with the sexual organs partially developed, and F. Silvestri has recorded the occurrence of workers with some of the characters of the females, in South America, in a nest of *Termes strunchii*.

Termitaria.—There is nothing in which termites display more variety than in their dwellings. These are sometimes not constructions at all. The primitive *Calotermes flavicollis*—in which there is no worker—frequently inhabits rotten places in trees; at most it increases these a little by excavation, and modifies the passages by slight and imperfect barricades. In the case of this species the community never attains a greater number than one thousand individuals, and even this is comparatively rare. On the other hand, we have the huge solid structures, 10 or 20 ft. high, delineated by Smeathman with cattle standing on their summits. Saville Kent has observed termitaria in Australia 18 ft. high. In equatorial Africa termitaria are frequently 12 to 25 ft. high and sharp-pointed. As a rule large termitaria do not occur in considerable numbers in a restricted area, but there are exceptions even to this. At Somerset, Cape York, there is one of the most remarkable termite cities of the world. Viewed from the sea, it appears as if the plain for a mile or more in extent were covered with pointed pillars, varying, according to different accounts, from 6 to 13 ft. in height, broad at the base and tapering to the summit, forming regular symmetrical pyramids. In this part of Australia there is also found the "compass," "magnetic," or "meridian" termite, the mounds of which have somewhat the shape of a tombstone, and have always the same orientation, the wider face of the structure always extending north to south. It has been suggested that this is connected with the necessity of regulating the temperature or the amount of desiccation of the nest, but there is no evidence whatever on the point. A termitarium on being opened displays a vast number of irregular chambers separated by thin partitions (fig. 5, *f*), the royal cell being placed in the middle (fig. 5, *c*). The material used is of an earthy nature, but the interiors of many earthy termitaria are largely composed of woody fibre, the refuse proceeding from the alimentary canals of the insects being used for this purpose. A considerable number of the larger termites use fungi for their foodstuff. There are special chambers where these are cultivated, the matter on which the fungus is grown being of a woody nature and sponge-like in its structure. The fungi make their appearance as small globules. Probably the spores or mycelium are placed in the mass when it is formed by the termites; but very little is yet known as to this fungus and its mode of treatment by them.

TERMONDE (Flemish *Dendermonde*), a town of Belgium in the province of East Flanders, situated 25 m. S.W. of Antwerp at the junction of the Dender and the Scheldt. Pop. (1904) 10,141. It is still one of the five fortified places in Belgium, although its defences are not modernized. It was before Termonde that Louis XIV. in 1667 was compelled to beat an ignominious retreat through its defenders opening the dikes and flooding the country. The church of Notre Dame contains two fine pictures by Van Dyck, and one masterpiece of Crayer's. The fonts are of the 12th century.

TERN (Norsk *taerne*, *tenne* or *tende;* Swedish *tärna;* Dutch *Stern*[1]), the name now applied generally to a group of sea-birds,

[1] "Starn" was used in Norfolk in the 19th century as a name for the bird commonly known as the black tern, thus confirming Turner, who, in 1544, describes what seems to have been the same

the sub-family Sterninae of the gulls or Laridae, but, according to P. J. Selby, properly belonging, at least in the Farne Islands, to the species known by the book-name of Sandwich tern, all the others being those called sea-swallows—a name still most commonly given to the whole group throughout Britain from their long wings, forked tail and marine habit. In F. Willughby's *Ornithologia* (1676), however, the word tern is used for more than one species, and, though it does not appear in the older English dictionaries, it may well have been from early times as general a name as it is now.

Setting aside those which are but occasional visitors to the British Islands, six species of terns may be regarded as indigenous, though of them one has ceased from ordinarily breeding in the United Kingdom, while a second has become so rare and regularly appears in so few places that mention of them must for prudence sake be avoided. This last is the beautiful roseate tern, *Sterna dougalli*; the other is the black tern, *Hydrochelidon nigra*, belonging to a genus in which the toes are only half-webbed, of small size and dark leaden-grey plumage. It is without doubt the *Sterna* of Turner, and in former days was abundant in many parts of the fen country,[1] to say nothing of other districts. Though nearly all its ancient abodes have been drained, and for its purposes sterilized these many years past, not a spring comes but it shows itself in small companies in the eastern counties of England, evidently seeking a breeding-place. All around the coast the diminution in the numbers of the remaining species of terns is no less deplorable than demonstrable.

The Sandwich tern, *S. cantiaca*—named from the place of its discovery, though it has long since ceased to inhabit that neighbourhood—is the largest of the British species, equalling in size the smaller gulls and having a dark-coloured bill tipped with yellow, and dark legs. Through persecution it has been exterminated in all its southern haunts, and is become much scarcer in those to which it still resorts. It was, however, never so abundant as its smaller congeners, the so-called common and the arctic tern—two species that are so nearly alike as to be beyond discrimination on the wing by an ordinary observer, and even in the hand require a somewhat close examination.[2] The former of these has the more southern range, and often affects inland situations, while the latter, though by no means limited to the Arctic circle, is widely distributed over the north and mostly resorts to the sea-coast. Yet there are localities where, as on the Farne Islands, both meet and breed, without occupying stations apart. The minute diagnosis of these two species cannot be briefly given. It must suffice here to state that the most certain difference, as it is the most easily recognizable, is to be found in the tarsus, which in the arctic tern is a quarter of an inch shorter than in its kinsman. The remaining native species is the lesser tern, *S. minuta*, one of the smallest of the genus and readily to be distinguished by its permanently white forehead. All the species already mentioned, except the black tern, have much the same general coloration—the adults in summer plumage wearing a black cap and having the upper parts of the body and wings of a more or less pale grey, while they are mostly lighter beneath. They generally breed in association, often in the closest proximity—their nests, containing three eggs at most, being made on the shingle or among herbage. The young are hatched clothed in variegated down, and remain in the nest for some time. At this season the parents are almost regardless of human presence and expose themselves freely.

At least half-a-dozen other species have been recorded as occurring in British waters, and among them the Caspian tern, *S. caspia*, which is one of the largest of the genus and of wide distribution, though not breeding nearer to the shores of England than on Sylt and its neighbouring islands, which still afford lodgings for a few pairs. Another, the gull-billed tern, *S. anglica*, has also been not infrequently shot in England. All these species are now recognized—though the contrary was once maintained—as inhabitants of North America, and many go much farther. *S. forsteri* is the North American, and *S. melanogaster* the Indian tern.

Terns are found all over the world, and among exotic forms may be particularly mentioned the various species of noddy (*q.v.*). Often confounded with these last are the two species called in books sooty terns (*S. fuliginosa* and *S. anaestheta*), but by sailors "egg-birds" or "wide-awakes" from their cry. These crowd at certain seasons in innumerable multitude to certain islands within the tropics, where they breed, and the wonderful assemblage known as "wide-awake fair" on the island of Ascension has been more or less fully described from very ancient times. W. Dampier in his voyage to New Holland in 1699 particularly described and figured the sooty tern (*Voyages*, iii. p. 142), discriminating it from the noddy, from which it had not before been distinguished. (A. N.)

species as "nostrati lingua sterna appellata." In at least one instance the word has been confounded with one of the old forms of the modern STARLING (*q.v.*). To Turner's name, repeated by Gesner and other authors, we owe the introduction by Linnaeus of *Sterna* into scientific nomenclature. "Ikstern" is another Dutch form of the word.

[1] It was known there as carr-swallow, carr-crow (corrupted into "scarecrow"), and blue dar (*qu.*=daw?).

[2] Linnaeus's diagnosis of his *Sterna hirundo* points to his having had an "arctic" tern before him; but it is certain that he did not suspect that specific appellation (already used by other writers for the "common" tern) to cover a second species. Some modern authorities disregard his name as being insufficiently definite, and much is to be said for this view of the case. Undoubtedly "*hirundo*" has now been used so indiscriminately for one species or the other as to cause confusion, which is perhaps best avoided by adopting the epithets of Naumann (*Isis*, 1819, pp. 1847, 1848), who, acting on and confirming the discovery of Nitzsch (who first detected the specific differences), called the southern species *S. fluviatilis* and the northern *S. macrura*. Temminck's name *S. arctica*, applied to the latter a year afterwards, has, however, been most generally used for it.

TERNATE, a small island in the Malay Archipelago, off the west coast of Halmahera, in 0° 48′ N., 127° 19′ E. It is nearly circular in form, with an area of about 25 sq. m., and consists almost entirely of a remarkable volcano (5400 ft.) formed of three superimposed cones. Frequent destructive eruptions have occurred. On the island is the small town of Ternate, which, in spite of its good harbour, carried on no considerable trade or shipping, and has only 3000 inhabitants. But it is the headquarters of the Dutch residency of Ternate, which exercises authority over the area of the ancient kingdoms of Ternate and Tidore. The residency consists of the following groups of islands: the Halmahera group, the Bachian and the Obi group, the Sula Islands, the islands near the western half of New Guinea (Gebeh, Vaigeu, Salawati, Misol, collectively called the Papuan Islands), the western half of New Guinea as far as 141° E., with the islands in Geelvink Gulf on the north coast of New Guinea (Schouten Islands, Yapen, &c.), along with others on the south coast. To this residency also belong the state of Banggai in East Celebes, and the Banggai Islands. The residency stretches from 2° 43′ N. to 5° 45′ S., and 121° to 141° E., with an area of 155,800 sq. m. The Dutch government exercises direct authority only over parts of Ternate, Halmahera, Bachian and Obi islands. Its rule over the other groups it carries on through the sultans of Ternate and Tidore (*q.v.*). Both the island and town of Ternate suffer from their isolation, and have never regained the importance they had in former centuries. Pop. of the whole residency (1905) 108,415. The inhabitants are of Malay race and Mahommedans in religion. The breaking up of the old government of the Moluccas tended to make Ternate perhaps the most important Dutch-Indian political centre of the archipelago east of Celebes. Nominally the sultan is still ruler, but virtually his powers were greatly curtailed by his conventions with the Dutch-Indian government, under which he surrendered, with the concurrence of his grandees, many of his former rights to the Dutch resident, who became the *de facto* governor of the easternmost colonial possessions of Holland, especially since the transfer of Dutch New Guinea in 1901. Among the rights surrendered by the sultan of Ternate to the Dutch were those of granting monopolies and mining concessions, now vested in the Dutch resident. The island of Bachian is worked by a kind of chartered company. For surrendered rights and privileges the sultan and his grandees received monetary compensations in the shape of annual subventions, and these also have been paid for the losses formerly incurred by the wilful destruction of the nutmeg plantations, carried out in order to enhance the value of this commodity and monopolize its cultivation. The restrictions on nutmeg-growing have long since been removed, and many plantations, with free labour, have been started in Ternate since 1885. It is a curious fact that Christianity has declined in Ternate in modern times, though it was an early stronghold and the number of Europeans settled there has materially increased.

TERNI (anc. *Interamna Nahars*), a town, episcopal see, and the seat of a sub-prefecture of the province of Perugia, Italy, situated among the Apennines, but only 426 ft. above sea-level, in the valley of the Nera (anc. *Nar*), from which the town took its distinguishing epithet, 5 m. below its junction with the Velino, and 70 m. N. by E. of Rome by rail. Pop. (1906) 20,230 (town), 33,256 (commune). It has important iron and steel works and iron foundries, at which armour-plates, guns and projectiles are made for the Italian navy, also steel castings, machinery and rails, a royal arms factory, and lignite mining. Terni lies on the main railway line from Rome to Foligno and Ancona, and is the junction for Rieti and Sulmona. Its most interesting buildings are the cathedral (17th century, with remains of the earlier 13th century façade), the church of S. Francesco (partly dating from the 13th century, with some frescoes of the 14th), and other old churches. Its antiquities include traces of the city walls of rectangular blocks of travertine, remains of an amphitheatre of the time of Tiberius, a temple, theatre and baths (?), and numerous inscriptions. Remains have also been found of a pre-Roman necropolis. The excavations and the objects found are described by A. Pasqui and L. Lanzi in *Notizie degli scavi*, 1907, 595 seq. Five miles to the east are the falls of the Velino (*Cascate delle Marmore*). Alike in volume and in beauty these take a very high place among European waterfalls; the cataract has a total descent of about 650 ft., in three leaps of 65, 330 and 190 ft. respectively. They owe their origin to M'. Curius Dentatus, who in 272 B.C. first opened an artificial channel by which the greater part of the Lacus Velinus in the valley below Reate was drained. They supply the motive power for the factories of the town.

Terni is the ancient *Interamna* (*inter amnes*, " between the rivers, " *i.e.* the Nar and one of its branches), originally belonging to Umbria, and founded, according to a local tradition preserved in an inscription, in the year 672 B.C. It is first mentioned in history as being, along with Spoletium, Praeneste and Florentia, portioned out among his soldiers by Sulla. Its inhabitants had frequent litigations and disputes with their neighbours at Reate in connexion with the regulation of the Velinus, the waters of which are so strongly impregnated with carbonate of lime that by their deposits they tend to block up their own channel. The first interference with its natural course was that of M'. Curius Dentatus already referred to. In 54 B.C. the people of Reate appealed to Cicero to plead their cause in an arbitration which had been appointed by the Roman senate to settle disputes about the river, and in connexion with this he made a personal inspection of Lake Velinus and its outlets. In the time of Tiberius there was a project for regulating the river and its outlets from the lake, against which the citizens of Interamna and Reate energetically and successfully protested (Tac. *Ann.* i. 79). Similar questions arose as the river formed fresh deposits during the middle ages and during the 15th and 16th centuries. A branch of the Via Flaminia passed from Narnia to Forum Flaminii, and is given instead of the direct line in the Antonine and Jerusalem itineraries. A road led from here to the Via Salaria at Reate. Interamna is also mentioned in Cicero's time as being the place where Clodius wished to prove that he was on the night when he was caught in Caesar's house at the celebration of the rites of the Bona Dea. The Emperor Tacitus and his brother Florianus were probably natives of Interamna, which also has been claimed as the birthplace of Tacitus the historian, but with less reason. During most of the middle ages and up till 1860 Terni was subject to the popes. It was the scene of the defeat of the Neapolitans by the French on the 27th of November 1798.

TERPANDER, of Antissa in Lesbos, Greek poet and musician. About the time of the Second Messenian war, he settled in Sparta, whither, according to some accounts, he had been summoned by command of the Delphian oracle, to compose the differences which had arisen between different classes in the state. Here he gained the prize in the musical contests at the festival Carnea (676–2 B.C.; Athenaeus, 635 E.). He is regarded as the real founder of Greek classical music, and of lyric poetry; but as to his innovations in music our information is imperfect. According to Strabo (xiii. p. 618) he increased the number of strings in the lyre from four to seven; others take the fragment of Terpander on which Strabo bases his statement (Bergk, 5) to mean that he developed the citharoedic nomos (sung to the accompaniment of the cithara or lyre) by making the divisions of the ode seven instead of four. The seven-stringed lyre was probably already in existence. Terpander is also said to have introduced several new rhythms in addition to the dactylic, and to have been famous as a composer of drinking-songs.

Fragments (the genuineness of which is doubtful) in T. Bergk, *Poetae Lyrici Graeci*, iii.; see also O. Löwe, *De Terpandri Lesbii aetate* (1869), who places him about 676 B.C.

TERPENES, in organic chemistry, the generic name of a group of hydrocarbons of the general formula $(C_5H_8)_n$, and the more important oxygen derivatives, mainly alcohols, aldehydes and ketones, derived from them. They may be classified into several distinct groups: *hemiterpenes*, C_5H_8; *terpenes* proper, $C_{10}H_{16}$; *sesquiterpenes*, $C_{15}H_{24}$; and *polyterpenes* $(C_5H_8)_n$. In addition to these, a series of open-chain olefine terpenes is known.

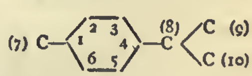
The chief sources of the terpenes and their derivatives are the essential oils obtained by the distillation or extraction by pressure of various plants, chiefly of the Coniferae and different species of *Citrus*. Certain of these oils consist very largely of hydrocarbons; for example, those of turpentine, citron, thyme, orange, pine-needle, goldenrod (from *Solidago canadensis*) and cypress, while others contain as their chief constituents various alcoholic and ketonic substances. With the exception of camphene, all the terpenes are liquids, boiling approximately between 160° and 190° C., so that it is almost impossible to separate them from the various essential oils by fractional distillation. In order to prepare the individual members pure, advantage is taken of the different physical properties of their derivatives. The terpenes all possess a characteristic odour and are fairly stable to alkalis, but are easily decomposed by acids or by heating to a sufficiently high temperature. Many polymerize readily, or are transformed into isomers by boiling with dilute alcoholic sulphuric acid. Some oxidize rapidly on exposure to air, passing into resinous substances. The formation of addition compounds with the halogens, halogen hydrides, and with nitrosyl chloride, is characteristic of many, whilst others unite readily with nitrogen peroxide. According to A. v. Baeyer (*Ber.*, 1895, 28, p. 648; 1896, 29, p. 10) the nitrosochlorides are not simple addition products, but bimolecular compounds or bisnitrosochlorides.

Hemiterpenes

The best known is Isoprene, C_5H_8, which is obtained on distilling caoutchouc or gutta-percha. It was synthesized by W. Euler (*Ber.*, 1897, 30, p. 1989) by distilling the addition compound of methyl iodide and 2·3·5-trimethylpyrollidine with caustic potash. It is an unstable liquid which boils at 33·5° C., and on heating rapidly polymerizes to dipentene, the same change being effected by hydrochloric acid. In ethereal solution it combines with bromine to form an unstable liquid dibromide; it also unites with one molecule of hydrobromic acid to form the same tertiary bromide as dimethylallylene; this points to its being β-methyldivinyl, $CH_2:C(CH_3)\cdot CH:CH_2$ (V. A. Mokiewsky, *Jour. Soc. Phys. Chim. Russ.*, 1900, 32, p. 207).

Terpenes Proper

The terpenes proper may be subdivided into the simple monocyclic terpenes and the more complex (usually bicyclic) terpenes. The monocyclic terpenes are hydro derivatives of paracymene. A. v. Baeyer proposed the following nomenclature: the dihydroparacymenes are called terpadienes, the tetrahydrocymenes becoming terpenes and the hexahydrocymene terpan, the carbon atoms being numbered as shown in the inset formula:



In the more complex terpenes the name camphene is retained, and camphane is used for the dihydrocamphene. G. Wagner (*Ber.*, 1894, 27, p. 1636 Anm.) designates the hexahydrocymenes menthans, the tetrahydrocymenes menthenes, and the dihydrocymenes menthadienes. The position of the double linking in the molecule is shown by the use of the symbol Δ followed by the number of the carbon atom immediately preceding it.

Monocyclic Terpene Group

Limonene, Δ1:8(9) terpadiene, $C_{10}H_{16}$, is known in three forms, namely *d*-limonene, *l*-limonene, and *i*-limonene or dipentene. *d*-Limonene is the chief constituent of oil of orange-rind, and is also found in oil of lemon and oil of bergamot. *l*-Limonene is found in oil of fir-cones and in Russian peppermint oil. Both are pleasant-smelling liquids, which boil at 175–176° C. They differ from each other only in rotatory power. Dry hydrochloric acid gas converts them into optically active limonene hydrochloride, while in the moist condition it gives dipentene dihydrochloride. When heated to a sufficiently high temperature they are converted into dipentene. Four optically active nitrosochlorides are known, two corresponding to each of the active limonenes, and these on heating with alcoholic potash are converted into *d*- and *l*-carvoxime. Dipentene (*i*-limonene) is found widely distributed in many essential oils, *e.g.* of camphor, Russian turpentine, cubebs, bergamot, cardamom, &c., and is also a product of the dry distillation of many vegetable resins. It may be produced by heating many terpenes (pinene, camphene, sylvestrene, limonene) for several hours at 250–270° C.; or by the polymerization of isoprene at 300° C. To obtain pure dipentene it is best to heat dipentene hydrochloride with anhydrous sodium acetate and glacial acetic acid (O. Wallach, *Ann. Chem. Pharm.*, 1887, 239, p. 3). It is a pleasant-smelling liquid, which boils at 175–176° C., and polymerizes on heating to high temperatures. When warmed with alcoholic sulphuric acid it yields terpinene, whilst concentrated sulphuric acid or phosphorus pentasulphide convert it into paracymene. Dipentene dihydrochloride, $C_{10}H_{16}\cdot 2HCl$, best prepared by passing a current of hydrochloric acid gas over the surface of a glacial acetic acid solution of dipentene, crystallizes in rhombic tables which melt at 50° C. and boil at 118–120° C. (10 mm.). It is apparently a *trans*-compound, for A. v. Baeyer (*Ber.*, 1893, 26, p. 2863) has obtained a *cis*-dihydrochloride of melting-point 25° (*circa*), by the action of hydrochloric acid on cineol.

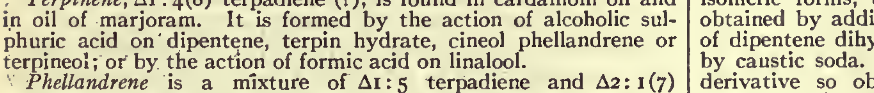
Terpinolene, Δ1:4(8) terpadiene, has not as yet been observed in essential oils. It is formed by the action of hot dilute sulphuric acid on terpineol, terpin hydrate and cineol. It is an inactive liquid boiling at 183–185° C., and is readily converted into terpinene by acids.

Terpinene, Δ1:4(8) terpadiene (?), is found in cardamom oil and in oil of marjoram. It is formed by the action of alcoholic sulphuric acid on dipentene, terpin hydrate, cineol phellandrene or terpineol; or by the action of formic acid on linalool.

Phellandrene is a mixture of Δ1:5 terpadiene and Δ2:1(7) terpadiene (pseudo-phellandrene) (F. W. Semmler, *Ber.*, 1903, 36, p. 1749). It is found as *d*-phellandrene in oil of water-fennel and oil of elemi, and as *l*-phellandrene in Australian eucalyptus oil and oil of bay. It is an exceedingly unstable compound, and must be extracted from the oils by distillation *in vacuo*. The hydrocarbons obtained from elemi oil and eucalyptus oil correspond to Δ1·5 terpadiene. A similar hydrocarbon was obtained by C. Harries and M. Johnson (*Ber.*, 1905, 38, p. 1832) by converting carvone hydrobromide into Δ6 terpenone-2, then, by phosphorus pentachloride, into chlor-2-phellandrene, which is finally reduced.

Sylvestrene, Δ1:8(9) meta-terpadiene, is found in Swedish and Russian oil of turpentine and in various pine oils. It boils at 175–176° C. and is dextro-rotatory. It is one of the most stable of the terpenes and gives a characteristic deep blue colour on the addition of a drop of sulphuric acid to its solution in acetic anhydride. On treating the hydrobromide with bromine in the presence of iodine, a product is obtained which on reduction yields meta-cymene (A. v. Baeyer and V. Villiger, *Ber.*, 1898, 31, p. 2067).

Carvestrene is obtained by the distillation of carylamine or vestrylamine hydrochloride (A. v Baeyer, *Ber.*, 1894, 27, pp. 3485 seq.). It is regarded by Baeyer as *i*-sylvestrene. It was synthesized by W. H. Perkin and G. Tattersall (*Proc. Chem. Soc.*, 1907, 22, p. 268) by the application of the Grignard reaction to the ethyl ester of γ-ketohexahydrobenzoic acid (1). By the action of magnesium methyl iodide this ester yields the lactone of γ-hydroxy-hexahydrometa-toluic acid, which is transformed by hydrobromic acid into the corresponding γ-bromo-hexahydro-meta-toluic acid. This latter substance by the action of pyridine yields tetrahydro-meta-toluic acid, the ester of which by magnesium methyl iodide is converted into Δ·1-meta menthenol-8 (2). The meta-menthenol on dehydration by potassium bisulphate yields carvestrene (3) of boiling-point 179–180° C.



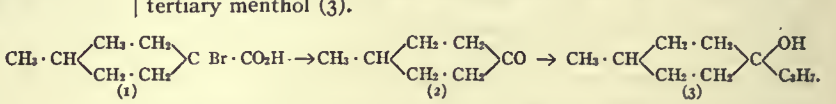
(1) (2) (3)

A synthetical monocyclic terpene, viz. 1-methyl-4-isopropyl dihydrocymene was prepared by A. v. Baeyer (*Ber.*, 1893, 26, p. 232). Succino-succinic ester is converted into the methyl isopropyl derivative, which on hydrolysis and elimination of carbon dioxide yields 1-methyl-4-isopropyldiketohexamethylene. This ketone is then reduced to the secondary alcohol, the hydroxyl groups replaced by bromine, and hydrobromic acid is then removed from the bromo-compound by boiling it with quinoline, leaving the terpene. It is a liquid which boils at 174° C. and shows a complete terpene character.

Alcohol and Ketone Derivatives

Menthol (terpan-ol-3), $C_{10}H_{20}O$. The *laevo* variety is the chief portion of oil of peppermint; it may be prepared by reducing the menthone obtained by E. Beckmann and M. Pleissner (*Ann.*, 1891, 262, p. 21) from pulegone hydrobromide with sodium and alcohol. It crystallizes in prisms which melt at 43° C. and boil at 212° C. It is readily oxidized by chromic acid to the corresponding ketone menthone. By the action of phosphorus pentoxide, or zinc chloride, it is converted into menthene, $C_{10}H_{18}$, and when heated with anhydrous copper sulphate to 250° C. it yields para-cymene. It is reduced by hydriodic acid and phosphorus to hexahydrocymene. The phosphorus haloids yield haloid esters of composition $C_{10}H_{19}Cl$, which, according to I. L. Kondakow (*Jour. prakt. Chem.*, 1899 [2], 60, p. 257) are to be regarded as tertiary esters; a similar type of reaction is found in the case of carvomenthol. A *d*-menthol has been prepared from the *i*-mixture obtained by reducing menthone with sodium. The mixture is benzoylated, and the liquid *d*-menthol benzoate separated and hydrolysed.

Tertiary menthol (terpan-ol-4), a liquid boiling at 97–101° C. (20 mm.), has been obtained by the hydrolysis of the ester prepared by heating menthene with trichloracetic acid (A. Reychler and L. Masson, *Ber.*, 1896, 29, p. 1844). It possesses a faint peppermint odour. W. H. Perkin, junr. (*Proc. Chem. Soc.*, 1905, 21, p. 255) synthesized it from 1·4 methyl*cyclo*hexanone: sodium carbonate converts α-bromhexahydro-para-toluic acid (1) into Δ·1-tetrahydro-para-toluic acid and α-oxyhexahydro-para-toluic acid, and the latter on treatment with dilute sulphuric acid yields 1·4-methyl*cyclo*hexanone (2), which by the action of magnesium isopropyl iodide and subsequent hydrolysis is converted into tertiary menthol (3).

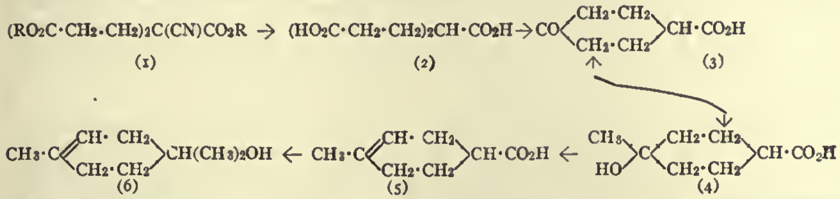


(1) (2) (3)

Terpin (terpan-diol 1·8), $C_{10}H_{18}(OH)_2$, is known in two stereoisomeric forms, *cis*-terpin and *trans*-terpin. The *trans*- form is obtained by adding silver acetate to a glacial acetic acid solution of dipentene dihydrochloride, filtering and neutralizing the filtrate by caustic soda. It is then extracted with ether, and the acetyl derivative so obtained is hydrolysed by alcoholic potash. It crystallizes in prisms, which melt at 156-158° C., and boil at 263–265° C. It is converted into terpineol by dilute sulphuric acid. The *cis*-compound melts at 104–105° C. and may be prepared by heating its hydrate. Terpin hydrate, $C_{10}H_{18}(OH)_2\cdot H_2O$, crystallizes in prisms which melt at 116° C. It is prepared by acting with dilute mineral acids on limonene or dipentene. When boiled with glacial acetic acid it is converted into terpineol, while concentrated hydriodic acid at 210° C. reduces it to hexahydrocymene. When heated with dilute sulphuric acid it gives a number of compounds, which may be considered as arising from the loss of one or two molecules of water from one molecule of terpin.

Cineol, $C_{10}H_{18}O$, is an inner oxide of terpin. It is found in the oils of wormseed, cajaput, eucalyptus, laurel, galanga, camphor and of lavender. It may be prepared by passing a current of dry hydrochloric acid gas into wormseed oil, the precipitated hydrochloride being then distilled in a current of steam (O. Wallach and W. Brass, *Ann.*, 1884, 225, p. 297). It is an inactive liquid, which boils at 176° C. The oxygen atom in the molecule does not appear to possess either an alcoholic, ketonic, aldehydic or acid function.

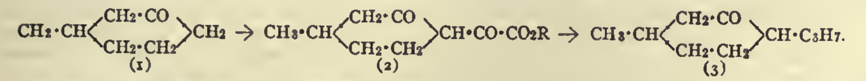
Terpineol (Δ1-terpen-ol-8), $C_{10}H_{17}(OH)$. The term "terpineol" has been used to denote what is now known to be a mixture of various isomeric alcohols. Liquid terpineols have been isolated from the oils of *Erigeron canadense*, of marjoram and of camphor. Liquid terpineol is generally prepared by the action of dilute sulphuric acid on terpin hydrate. It consists of a mixture of various isomers, from which a solid terpineol melting at 35° C. and an isomeric Δ·8(9) terpen-ol-1, melting at 32° C., have been isolated (K. Stephan and J. Halle, *Ber.*, 1902, 35, p. 2147. See also G. Bouchardat, *Comptes rendus*, 1887, 104, p. 996; 1895, 121, p. 141; Schimmel & Co., *Semi-annual Reports*, Oct. 1897, p. 11; J. Godlewsky, *Chem. Centralblatt*, 1899 (I.), p. 1241). Solid terpineol exists in active and racemic forms. The active form was obtained by F. W. Semmler (*Ber.*, 1895, 28, p. 2190) by replacing the halogen atoms in the active monohydrobromide of limonene by the hydroxyl group; it has also been obtained by the action of acetic acid on linalool. The racemic variety has been prepared by the action of formic acid on geraniol, and was synthesized by the following method (W. H. Perkin, junr., *Jour. Chem. Soc.*, 1904, 85, p. 654). γ-Cyanpentane tricarboxylic ester (1) (prepared by the action of cyanacetic ester on β-iodopropionic ester) is hydrolysed to pentane-αγε-tricarboxylic acid (2), which when boiled with acetic anhydride and distilled gives δ-ketohexahydrobenzoic acid (3). The ester of this acid, when treated with the Grignard reagent, yields δ-oxyhexahydrotoluic acid (4), which is converted into the corresponding brom-compound by fuming hydrobromic acid. This latter compound on treatment with dilute alkali or pyridine yields Δ·3-tetrahydro-para-toluic acid (5), the ester of which with magnesium and methyl iodide furnishes terpineol (6):—



This synthesis determines the constitution of terpin (7) and of dipentene (8), since the former is produced by the action of 5 per cent. sulphuric acid on terpineol, and the latter by heating terpineol with acid sodium sulphate.

Terpineol adds on nitrosyl chloride to form a nitrosochloride, which on elimination of hydrochloric acid yields the oxime of an unsaturated oxyketone; this on boiling with acids is converted into inactive carvone. When reduced by the method of Sabatier and Senderens it forms hexahydrocymene (A. Haller, *Comptes rendus*, 1905, 140, p. 1303); when oxidized with Caro's reagent it yields trioxyhexahydrocymene (A. v. Baeyer and V. Villiger, *Ber.*, 1899, 32, p. 3625). For an isomeric terpineol (Δ·8(9) terpenol-1) see A. v. Baeyer, *Ber.*, 1894, 27, pp. 443, 815.

Menthone (terpan-one-3), $C_{10}H_{18}O$, occurs with menthol in oil of peppermint. It was first obtained by M. Moriya (*Jour. Chem. Soc.*, 1881, 39, p. 77) by oxidizing menthol with chromic acid mixture at 120° C., and was described as an inactive compound; but R. W. Atkinson (ibid., 1882, 41, p. 50) showed that when menthol was oxidized at 135° C. a strongly dextro-rotatory menthone was produced. For the preparation of *l*-menthone and *d*-isomenthone (Beckmann's *d*-menthone) see E. Beckmann, *Ann.*, 1889, 250, p. 325; 1891, 262, pp. 21 seq. The menthone obtained by Beckmann by the reduction of pulegone hydrobromide was shown by C. Martine (*Ann. chim. phys.*, 1904 (8), 3, p. 49) to be not completely identical with *l*-menthone; it is consequently designated P-menthone. An inactive menthone has been synthesized as follows. β-Methyl pimelic ester is converted by sodium ethylate into methyl-1-*cyclo*hexanon-3-carboxylic ester-4, into which the isopropyl group is introduced (also in position 4) by the action of isopropyl iodide and sodium ethylate. The ester is then hydrolysed, and carbon dioxide eliminated from the carboxyl group, when inactive menthone is obtained (A. Einhorn and L. Klages, *Ber.*, 1901, 34, p. 3793). It boils at 204–206° C., whereas Beckmann's menthones boil at 208° C. A. Haller and C. Martine (*Comptes rendus*, 1905, 140, p. 130) synthesized natural menthone from isopropyl iodide and the sodium derivative of methyl-1-*cyclo*hexanone-3. It has also been prepared by condensing methylhexanone with ethyl acetate, the resulting methyl-1-acetyl-4-*cyclo*hexanone-3 being converted into the isopropyl derivative, yielding acetylmenthone, which is then hydrolysed to menthone (G. Leser, *Comptes rendus*, 1902, 134, p. 1115). A. Koltz and L. Hesse (*Ann.*, 1905, 342, p. 306) convert methylhexanone (1) by means of ethyl oxalate and subsequent hydrolysis into methylhexanone oxalic acid (2), the isopropyl ester of which on treatment with a methyl alcohol solution of caustic potash yields *d*-menthone (3).



O. Wallach (*Ann.*, 1900, 312, p. 171) showed that the oximes of cyclic ketones are converted by phosphorus pentoxide into iso-oximes, which are readily decomposed by concentrated hydrochloric acid to yield aliphatic amino-acids; in this way menthone may be converted into ε-amido-decylic acid,

$$(CH_3)_2CH{\cdot}CH(NH_2){\cdot}(CH_2)_2{\cdot}CH(CH_3){\cdot}CH_2{\cdot}CO_2H.$$

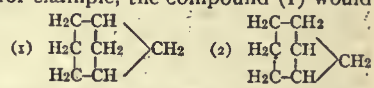
Diosphenol, $C_{10}H_{16}O_2$, which occurs in the essential oil of bucco leaves (*Borosma betulina*) may be synthesized by oxidizing oxymethylene menthone. Sodium in alcoholic solution reduces it to para-terpane-di-ol (2·3).

Pulegone (Δ 4(8)-terpenone-3), $C_{10}H_{16}O$, is an unsaturated ketone found in pennyroyal oil, from which it may be obtained by distillation *in vacuo*. It is a dextro-rotatory liquid which boils at 221–222° C. F. Tiemann (*Ber.*, 1897, 30, p. 22) synthesized it from citronellal by converting this compound into isopulegol acetate by acetic anhydride; this ester is hydrolysed, and the isopulegol oxidized to isopulegone, which on treatment with baryta yields pulegone. Pulegone reduces ammoniacal silver nitrate on long boiling. It is reduced by hydrogen to *l*-menthol. When heated with water to 250° C. it yields methyl-1-*cyclo*hexanone-3 and acetone. When methyl*cyclo*hexanone and acetone are condensed together in the presence of sodium methylate, an isomer of pulegone boiling at 215–216° C. is obtained. Pulegone combines with hydrobromic acid to form a hydrobromide, which on heating in methyl alcohol solution with basic lead nitrate is converted into isopulegone (Δ 8(9)-terpenone-3) (C. Harries and G. Röder, *Ber.*, 1899, 32, p. 3361). It is a laevo-rotatory liquid. A dextro-form (a mixture) is also obtained by the oxidation of isopulegol with chromic acid. On reduction it yields isopulegol and no menthol (cf. pulegone).

Carvone (Δ 6 : 8(9)-terpadiene-one-2), $C_{10}H_{14}O$, is an unsaturated optically active ketone which is found very widely distributed in nature. The dextro-form is the chief constituent of oil of caraway, and is also found in oil of dill; the laevo-form is found in oil of spearmint and kuromoji oil. The dextro-form is obtained practically pure by the fractional distillation of caraway oil; the laevo-form from the oils containing it, by first forming its addition compound with sulphuretted hydrogen, decomposing this by alcoholic potash, and distilling the product in a current of steam. It may be synthetically prepared from limonene nitrosochloride, alcoholic potash converting this compound into *l*-carvoxime, which on boiling with dilute sulphuric acid yields *l*-carvone; similarly terpineol nitrosochloride by the action of sodium ethylate yields oxydihydrocarvoxime, which on hydrolysis yields *i*-carvone. On heating with phosphoric acid carvone is converted into carvacrol (1-methyl-2-oxy-4-isopropylbenzene). Carvone is closely related to phellandrene, for C. Harries and M. Johnson (*Ber.*, 1905, 38, p. 1832), by reduction of carvone hydrobromide, obtained Δ 6-terpenone-2, which with phosphorus pentachloride gives chlor-2-α-phellandrene.

Bi-Cyclic Terpene Group

A nomenclature for the bicyclic hydrocarbons was devised by A. v. Baeyer (*Ber.*, 1900, 33, p. 3771). According to this system each hydrocarbon contains two tertiary carbon atoms, which are combined with each other three times, either directly or by means of other intervening carbon atoms, the combination forming a series of "bridges." These bridges are distinguished by numbers, denoting the number of carbon atoms contained in them, the direct union of the two tertiary carbon atoms being designated as 0; if one carbon atom intervenes, then the number 1 is used, and so on. Thus three numbers serve as the "characteristic" for the compound. Hydrocarbons of this class with five atoms of carbon are termed "*bicyclo*pentanes," with six atoms of carbon "*bicyclo*hexanes," &c. Thus, for example, the compound (1) would be called "*bicyclo*-(1 · 1 · 3)-heptane," and (2) would be "*bicyclo*-(0 · 1 · 4)-heptane."

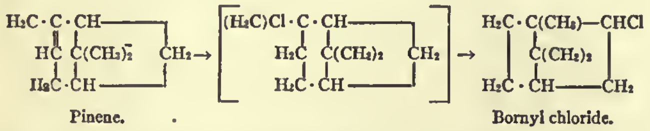


Thujene (tanacetene), $C_{10}H_{16}$, is a derivative of *bicyclo*-(0 · 1 · 3)-hexane. The name was first given to the hydrocarbon obtained by F. W. Semmler (*Ber.*, 1892, 25, p. 3345) on the dry distillation of thujylamine hydrochloride. It is a liquid which boils at 60–63° (14 mm.), and has been shown by L. Tschugaeff to be a monocyclic hydrocarbon, for which he proposes the name "isothujene." The true thujene was prepared by L. Tschugaeff (*Ber.*, 1900, 33, p. 3118) by heating the methyl xanthogenic ester obtained from thujyl alcohol. It is exceedingly unstable. The isomeric β-thujene was also obtained by the same investigator by the dry distillation of trimethylthujyl ammonium hydroxide. It boils at 150–151° C., and possesses a different rotatory power.

Sabinene, $C_{10}H_{16}$, also a *bicyclo*-(0 · 1 · 3)-hexane derivative, is found in oil of savine, from which it was first obtained by F. W. Semmler (*Ber.*, 1900, 33, p. 1455). On shaking with dilute sulphuric acid it yields terpinenol (Δ1-terpen-ol-4) (O. Wallach, *Ber.*, 1907, 40, p. 592).

Pinene, $C_{10}H_{16}$, derived from *bicyclo*-(1 · 1 · 3)-heptane, is found in many essential oils, and is the chief constituent of oil of turpentine; the *l*-variety is found in French oil of turpentine, the *d*-variety in Russian, American and Swedish oil of turpentine. Pinene is also a constituent of the oils of sage, lemon, eucalyptus, olibanum, bay, fennel, sassafras, rosemary and of valerian. The active varieties are obtained by the fractional distillation of the various oils of turpentine. The inactive variety is obtained by heating pinene nitrosochloride with an excess of aniline (O. Wallach, *Ann.*, 1889, 252, p. 132; 1890, 258, p. 243), or better with methylaniline (W. A. Tilden). The three varieties boil at 155–156° C. Pinene readily absorbs oxygen from the air, resinous products being formed, together with small quantities of formic and acetic acids.

Acid oxidizing agents convert it into terephthalic and terebic acids, whilst alkaline potassium permanganate in dilute solution oxidizes it to pinene glycol, $C_{10}H_{16}(OH)_2$, pinonic acid, $C_{10}H_{16}O_3$, pinic acid, $C_9H_{14}O_4$, &c., the products of the reaction varying according to the temperature (G. Wagner, *Ber.*, 1894, 27, p. 2270; F. Tiemann and F. W. Semmler, *Ber.*, 1895, 28, pp. 1344, 1778). Concentrated sulphuric acid converts it into camphene; and an alcoholic solution of sulphuric acid gives terpinene and terpinolene. When heated to 250–270° C. it yields dipentene; the moist halogen acids at ordinary temperature convert it into the dihalogen halides of dipentene. Dry hydrochloric acid gives pinene hydrochloride (artificial camphor), $C_{10}H_{17}Cl$, a white crystalline solid identical with bornyl chloride which melts at 131° C. Elimination of halogen hydride by means of a weak alkali (*e.g.* soap, silver acetate, &c.) converts it into camphene. Thus the conversion of pinene into its hydrochloride is probably accompanied by an intramolecular rearrangement—



Pinene. Bornyl chloride.

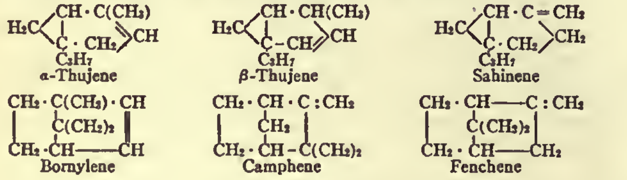
Nitric acid in aqueous alcoholic solution converts it into terpin hydrate. Pinene nitrosochloride, $C_{10}H_{16}NOCl$, was first obtained in 1874 by W. A. Tilden (*Jahresb.*, 1874 p. 214) from nitrosyl chloride and a mixture of pinene and chloroform. O. Wallach (*Ann.*, 1889, 253, p. 251) prepared it by the action of acetic acid and ethyl nitrite on oil of turpentine in presence of fuming hydrochloric acid. W. A. Tilden (*Jour. Chem. Soc.*, 1904, 85, p. 759) showed that strongly active pinene gives bad yields of the nitrosochloride, since, being bimolecular, its formation is retarded by the inversion of half of the terpene. The nitrosochloride melts at 115° C. (*circa*) and is a white pleasant-smelling powder. Alcoholic potash converts it into nitrosopinene, $C_{10}H_{16}NO$.

Bornylene, $C_{10}H_{16}$, derived from *bicyclo*-(1 · 2 · 2)-heptane, is prepared by heating bornyl iodide to 170° C. for several hours with a concentrated solution of alcoholic potash (G. Wagner, *Ber.*, 1900, 33, p. 2121), or by decomposition of the methyl esters of the *l*- and *d*-bornyl xanthates, the former yielding *d*-bornylene and the latter *l*-bornylene (L. Tschugaeff, *Chem. Centralblatt*, 1905, i., p. 94).

Camphene, $C_{10}H_{16}$, also a *bicyclo*-(1 · 2 · 2)-heptane derivative, is a constituent of the oils of citronella, camphor, ginger and of rosemary, and also of French and American oil of turpentine. It may be obtained by the action of sulphuric acid on pinene; by heating pinene hydrobromide or hydrochloride with sodium acetate or glacial acetic acid to 200° C.; or by heating bornyl chloride with aniline (O. Wallach, *Ber.*, 1892, 25, p. 916). According to Konowalow it is best prepared by heating borneol with a diluted sulphuric acid (1 · 2) for about 6–8 hours, between 60–100° C., with continual shaking, a yield of about 90 per cent. being obtained. The melting- and boiling-points of camphene vary slightly according to the sources from which it is obtained, the former being about 50° C. and the latter about 159–161° C. It is known in *d*-, *l*- and *i*- forms. It combines with hydrochloric acid to form a hydrochloride, which on reduction with sodium and alcohol yields camphene. Many different oxidation products may be obtained from camphene by varying the conditions of experiment (J. Bredt and W. Jagelki, *Ann.*, 1900, 310, p. 114; G. Wagner, *Ber.*, 1890, 23, p. 2311; S. Moycho and F. Zienkowski, *Ann.*, 1905, 340, p. 17; J. E. Marsh and J. A. Gardner, *Jour. Chem. Soc.*, 1891, 59, p. 648; 1896, 69, p. 74).

Fenchene, $C_{10}H_{16}$, a *bicyclo*-(1 · 2 · 2)-heptane derivative, is not found in any naturally occurring products. The hydrocarbon may be obtained by the reduction of fenchone and elimination of water from the resulting fenchyl alcohol, or by the elimination of halogen hydride from the fenchyl halogen compounds (O. Wallach, *Ann.*, 1892, 263, p. 145; 1898, 302, pp. 371 seq.).

The above *bicyclo*-terpene hydrocarbons are most probably best represented by the following formulae (pinene is given above):—



α-Thujene β-Thujene Sabinene

Bornylene Camphene Fenchene

Alcohol and Ketone Derivatives

Borneol (Borneo camphor), $C_{10}H_{17}OH$ occurs in the pith cavities of *Dryobalanops camphora*, and in the oils of spike and rosemary; esters are found in many fir and pine oils. It may be prepared by heating camphor with alcoholic potash (M. Berthelot, *Ann.*, 1859, 12, p. 363); or by reducing camphor in alcoholic solution with sodium (O. Wallach, *Ann.*, 1885, 230, p. 225; J. Bertram and H. Walbaum, *Jour. prak. Chem.* 1894 (2), 49, p. 12). L. Tschugaeff (*Chem. Centralblatt.* 1905 i., p. 94) obtains pure *d*-borneol as follows:—Impure *d*-borneol (containing isoborneol) obtained in the reduction of camphor is dissolved in xylene and converted into the sodium salt by metallic sodium. This salt is then turned into the xanthate, $C_{10}H_{17}OCS_2Na$, which with methyl sulphate yields the corresponding methyl ester. The unchanged isoborneol is removed by steam distillation, which also decomposes any methyl xanthate of isoborneol that may have been formed. The residue is crystallized and hydrolysed, when pure borneol is obtained. It behaves as a secondary alcohol. Nitric acid oxidizes it to camphor and when heated with potassium bisulphate, it gives camphene. With phosphorus pentachloride it forms a bornyl chloride, identical with pinene hydrochloride.

Isoborneol is a tertiary alcohol which may be obtained by dissolving camphene in glacial acetic acid, adding dilute sulphuric acid and heating to 50–60° C. for a few minutes, the isobornyl acetate so formed being then hydrolysed (J. Bertram and H. Walbaum, *loc. cit.*). It crystallizes in leaflets, which readily sublime. Chromic acid oxidizes it to camphor.

Thujone (tanacetone), $C_{10}H_{16}O$, is found in many essential oils. Oil of thuja contains chiefly α-thujone, and oil of tansy chiefly β-thujone. Oil of artemisia and oil of sage contain a mixture of the two, whilst oil of absinthe contains principally the β-variety. The two forms may be obtained by fractional distillation of the oils, followed by a fractional crystallization of their semicarbazones from methyl alcohol. α-Thujone is laevo-rotatory and when warmed with alcoholic potash it is partially converted into β-thujone. Sodium in the presence of alcohol reduces it to thujyl alcohol, which on re-oxidation is converted into β-thujone. The β-form is dextro-rotatory and is partially converted into the α-variety by alcoholic potash. When heated to 280° thujone is transformed into the isomeric carvotanacetone (Δ6-terpenone-2). On boiling with ferric chloride it yields carvacrol. Hot dilute sulphuric acid converts it into isothujone (dimethyl-1 · 2-isopropyl-3-*cyclo*pentene-1-one-5). Thujone behaves as a saturated compound and forms a characteristic tribromide. When heated with zinc chloride it yields hydropseudocumene. According to F. W. Semmler (*Ber.*, 1900, 33, p. 275; 1903, 36, p. 4367) it is to be considered as a methyl-2-isopropyl-5-*bicyclo*-(0 · 1 · 3)-hexanone-3.

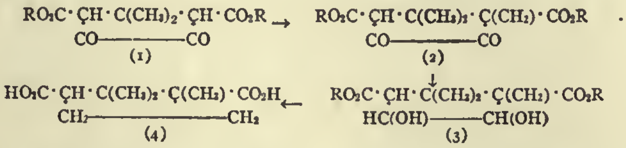
Carone, $C_{10}H_{16}O$, is a trimethyl-3 · 7 · 7-*bicyclo*-(0 · 1 · 4)-heptanone-2, obtained by acting with alcoholic potash on dihydrocarvone hydrobromide (A. v. Baeyer, *Ber.*, 1896, 29, pp. 5, 2796; 1898, 31, pp. 1401, 2067). It is a colourless oil, having the odour of camphor and peppermint, and boiling at 210° C. It is known in *d*-, *l*-, and *i*-forms. It does not combine with sodium bisulphite. When heated it is transformed into carvenone. It is stable to cold potassium permanganate solution, but on heating gives a dibasic acid, caronic acid, $C_6H_8(CO_2H)_2$, which Baeyer suggested was a *gem*-dimethyltrimethylene-1 · 2-dicarboxylic acid. This was confirmed by W. H. Perkin, junr. (*Jour. Chem. Soc.*, 1899, 75, p. 48) who synthesized the acid from dimethylacylic ethyl ester. This ester with ethyl malonate yields ethyldimethylpropanetricarboxylic ester, which on hydrolysis and subsequent heating is converted into ββ-dimethyl glutaric acid. The α-bromdimethyl ester of this acid when heated with alcoholic potash yields *cis*-, and *trans*-caronic acids. Eucarvone, $C_{10}H_{14}O$, is a trimethyl-3·7·7-*bicyclo*-(0·1·4)-heptene-3-one-2. O. Wallach (*Ann.*, 1905, 339, p. 94) suggests that the ketone possesses the structure of a trimethyl-1 · 4 · 4-*cyclo*heptadiene-5 · 7-one-2. Phosphorus pentachloride converts it into 2-chlorcymene (A. Klages, *Ber.*, 1899, 32, p. 2558).

Camphor, $C_{10}H_{16}O$, is a trimethyl-1 · 7 · 7-*bicyclo*-(1 · 2 · 2)-heptanone-2. The *d*-variety is found in the camphor tree (*Laurus camphora*), from which it may be obtained by distillation in steam. The *l*-variety is found in the oil of *Matricaria parthenium*. It crystallizes in transparent prisms which possess a characteristic odour, sublimes readily and is easily soluble in the usual organic solvents. It boils at 209° C. and melts at 176° C. (*circa*). The *d*-form may also be obtained by the distillation of calcium homocamphorate (A. Haller, *Bull. Soc. Chim.*, 1896 (3), 15, p. 324). When heated with phosphorus pentoxide it yields cymene, and with iodine, carvacrol. Nitric acid oxidizes it to camphoric acid, $C_8H_{14}(CO_2H)_2$, camphoronic acid, $C_9H_{14}O_6$, and other products. It forms an oxime with hydroxylamine which on dehydration yields a nitrile, from which by hydrolysis campholenic acid, $C_9H_{15}CO_2H$, is obtained. It combines with aldehydes to form alkylidene compounds, and yields oxymethylene compounds when subjected to the "Claisen" reaction. It does not combine with the alkaline bisulphites. It is readily substituted by chlorine and bromine; and with fuming sulphuric acid forms a camphor sulphonic acid. Sodium reduces it, in alcoholic solution, to borneol. When heated with sodium formate to 120° C. it is converted into bornylamine. Caro's acid converts it into campholid, and a compound $C_{10}H_{16}O_4$ (A. v. Baeyer and V. Villiger, *Ber.*, 1899, 32, p. 3630). When heated with concentrated sulphuric acid to 105–110° C. it yields carvenone and 4-aceto-1 · 2-xylol (J. Bredt, *Ann.*, 1901, 314, p. 371).

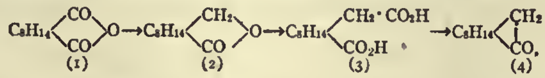
A vast amount of work has been done on the constitution of the camphor molecule. The earlier investigations on the ready formation of benzene derivatives by the breaking down of camphor led to the view that the molecule was a simple six-membered carbon ring. Subsequent research, however, showed that the formula proposed by J. Bredt (*Ber.*, 1893, 26, p. 3047), in which camphor is to be regarded as a *bicyclo*-heptane derivative, is correct. This formula is based on the fact that camphoronic acid yields trimethylsuccinic, isobutyric, and carbonic acids, and carbon on dry distillation, and Bredt suggested that it was an $\alpha\alpha\beta$-trimethylcarballylic acid,

$$HO_2C\cdot CH_2\cdot C(CH_3)(CO_2H)\cdot C(CH_3)_2CO_2H,$$

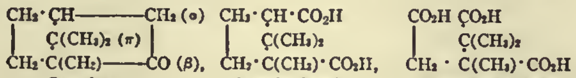
a conclusion confirmed by its synthesis (see below). The Bredt formula is also supported by the synthesis of *r*-camphoric acid by G. Komppa (*Ber.*, 1901, 34, p. 2472; 1903, 36, p. 4332). In this synthesis ethyl oxalate is condensed with $\beta\beta$-dimethyl glutaric ester, and the resulting diketoapocamphoric ester (1) is then methylated to diketocamphoric ester (2). The keto groups in (2) are converted in CH_2 groups as follows:—Sodium amalgam converts this ester into dioxycamphoric ester (3), which with hydriodic acid and phosphorus yields *r*-dihydrocamphoric acid. At 125° C. this compound combines with hydrobromic acid to form β-bromcamphoric acid, which on reduction with zinc and acetic acid yields *r*-camphoric acid (4):—



This series of reactions leads to a complete synthesis of camphor, since A. Haller (*Comptes rendus*, 1896, 122, p. 446) has shown that camphoric anhydride (1) on reduction yields campholid (2), which by the action of potassium cyanide and subsequent hydrolysis of the nitrile formed is converted into homocamphoric acid (3), the calcium salt of which yields camphor (4) on distillation:—



Thus camphor and its oxidation products are to be represented as



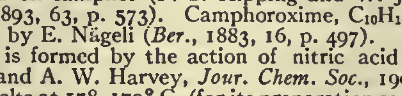
Camphor, Camphoric acid, Camphoronic acid.

Camphor yields three classes of halogen substitution derivatives known respectively as α, β and π compounds, the positions being shown in the formula above. The α compounds result by direct substitution, the β and π derivatives being formed in an indirect manner. Cyancamphor, $C_{10}H_{15}O\cdot CN$, is formed by passing cyanogen gas into sodium camphor, or by digesting sodium oxymethylene camphor with hydroxylamine hydrochloride (L. Claisen, *Ann.*, 1894, 281, p. 351).

π-Camphor sulphonic acid results from the action of fuming sulphuric acid on camphor (F. S. Kipping and W. J. Pope, *Jour. Chem. Soc.*, 1893, 63, p. 573). Camphoroxime, $C_{10}H_{16}O{:}NOH$, was first prepared by E. Nägeli (*Ber.*, 1883, 16, p. 497).

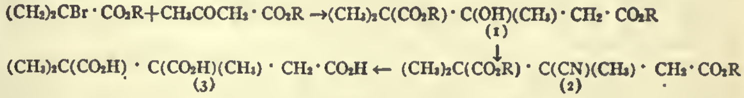
l-Camphor is formed by the action of nitric acid on *l*-borneol (W. J. Pope and A. W. Harvey, *Jour. Chem. Soc.*, 1901, 79, p. 76). *r*-Camphor melts at 178–179° C. (for its preparation see A. Debierne, *Comptes rendus*, 1899, 128, p. 1110; W. A. Noyes, *Amer. Chem. Jour.*; 1905, 27, p. 430).

Camphoric acid. Four optically active and two inactive forms of this acid are known. The most important is the *d*-form, which is produced by the oxidation of *d*-camphor with nitric acid. It crystallizes in plates or prisms which melt at 187° C. Potassium permanganate oxidizes it to oxalic acid and Balbiano's acid, $C_8H_{12}O_5$, together with small quantities of camphanic, camphoronic and trimethyl succinic acids. It yields two series of acid esters, the *allo*-esters (1), formed by the partial saponification of the neutral esters, and the *ortho*-esters (2), formed by heating the anhydride with alcohols or sodium alcoholates.



l-Camphoric acid results on oxidizing *l*-borneol or matricaria camphor. It melts at 187° C. *r*-Camphoric acid is formed on mixing alcoholic solutions of equimolecular quantities of the *d*- and *l*-acids, or by oxidizing *i*-camphor. It melts at 202–203° C.

Camphoronic acid, $C_9H_{14}O_6$. From a study of its distillation products J. Bredt (*Ber.*, 1893, 26, p. 3049) concluded that this acid was an $\alpha\alpha\beta$-trimethylcarballylic acid, a conclusion which was confirmed by its synthesis by W. H. Perkin, junr., and J. F. Thorpe (*Jour. Chem. Soc.*, 1897, 71, 1169):—Aceto-acetic ester is condensed with α-bromisobutyric ester, the resulting hydroxytrimethyl glutarate (1) converted into the chlor- and then into the corresponding cyan-trimethyl glutarate (2), which on hydrolysis with hydrochloric acid yields camphoronic acid (3) and some trimethyl glutaconic acid:—



Fenchone, $C_{10}H_{16}O$, is trimethyl-(2·7·7)-*bicyclo*-(1·2·2)-heptanone-3. It occurs in *d*- and *l*-forms, the former in oil of fennel and the latter in oil of thuja. It may be obtained from these oils by treating the fraction boiling between 190–195° C. with nitric acid and distilling the product in a current of steam. The fenchones are pleasant-smelling oils which boil at 192–193° C., and on solidification melt at 5–6° C. They do not combine with sodium bisulphite. They dissolve unchanged in cold concentrated hydrochloric and sulphuric acids, and are very stable; thus the monobromfenchone is only formed by heating the ketone with bromine to 100° C. under pressure (H. Czerny, *Ber.*, 1900, 33, p. 2287). On oxidation with potassium permanganate it yields acetic and oxalic acids together with dimethylmalonic acid. By the action of hot concentrated sulphuric acid it yields acetyl-ortho-xylene,

$$CH_3CO(4)C_6H_3(CH_3)_2(1\cdot 2)$$

(J. E. Marsh, *Jour. Chem. Soc.*, 1899, 75, p. 1058). When heated with phosphorus pentoxide to 115–130° C. it forms metacymene. Since it does not yield any oxymethylene compounds, it cannot contain the grouping—$CH_2\cdot CO$—in the molecule.

Hydrocarbons, $C_{10}H_{18}$, of the Terpene Series

Menthene, $C_6H_9(CH_3)(C_3H_7)$, is methyl-1-isopropyl-4-*cyclo*hexene-3. It is obtained by the action of anhydrous zinc chloride or copper sulphate on menthol (J. W. Brühl, *Ber.*, 1892, 25, p. 142), by boiling menthyl chloride with aniline (G. Wagner, *Ber.*, 1894, 27, p. 1636), by heating menthyl chloride with potassium phenolate (L. Masson, *Ber.*, 1896, 29, p. 1843), and by the dry distillation of the methyl ester of menthyl xanthate (L. Tschugaeff, *Ber.*, 1899, 32, p. 3333). It is a colourless liquid which boils at 167–168° C. When strongly heated with copper sulphate it yields cymene. According to Tschugaeff, the xanthate method alone gives a pure menthene of the above constitution, the menthene obtained from the dehydration of menthol being a *cyclo*hexene-4; and the one obtained by O. Wallach (*Ann.*, 1898, 300, p. 278) from *l*-menthylamine being a *cyclo*hexene-2.

Carvomenthene, $C_6H_9(CH_3)(C_3H_7)$, is probably methyl-1-isopropyl-4-*cyclo*hexene-1. It is prepared by heating carvomenthyl bromide with quinoline, or by heating carvomenthol with potassium bisulphate to 200° C. It is a liquid which boils at 175–176° C.

Camphane, $C_7H_{11}(CH_3)_3$ is 1·7·7-trimethyl-*bicyclo*-(1·2·2)-heptane. It is prepared by the action of sodium and alcohol on pinene hydriodide, or by reducing the hydriodide with zinc in acetic acid solution. It is a crystalline solid which melts at 153° C. and boils at 160° C.

Olefine Terpenes

Myrcene, $C_{10}H_{16}$, was first isolated by F. B. Power and C. Kleber from oil of bay (Schimmel & Co., *Bulletin*, April 1895, p. 11); it is also found in oil of sassafras leaves. It is obtained from bay oil by shaking the oil with a 5 per cent. solution of caustic soda, followed by fractionation *in vacuo*. It boils at 67–68° C. (20 mm.), and polymerizes when heated for some time. When oxidized by potassium permanganate it yields succinic acid. By the action of glacial acetic acid in the presence of dilute sulphuric acid, a liquid is produced, which on hydrolysis yields myrcenol, $C_{10}H_{18}O$, an alcohol which is probably an isomer of linalool (P. Barbier, *Comptes rendus*, 1901, 132, p. 1048). The hydrocarbon is probably to be considered as being $(CH_3)_2C : CH\cdot(CH_2)_2\cdot C(:CH_2)\cdot CH : CH_2$ (Enklaar, *Bulletin of Rouse-Bertrand fils*, Nov., 1906, p. 92). Ocymene is an isomer which can be extracted from the leaves of the basil. Enklaar (*loc. cit.*) represents it as $(CH_3)_2C : CH\cdot CH_2\cdot CH : C(CH_3)\cdot CH : CH_2$. Anhydro-geraniol, $C_{10}H_{16}$, the first olefine terpene isolated, was prepared in 1891 by F. W. Semmler; it is formed when geraniol is heated with potassium bisulphate to 170° C.

Alcohols, Aldehydes and Ketones

d-*Citronellol*, $C_{10}H_{19}OH$ or $CH_3\cdot C(:CH_2)\cdot(CH_2)_3\cdot CH(CH_3)\cdot(CH_2)_2OH$, or 2·6 dimethyl-octene-1-ol-8 occurs in Réunion geranium oil and was first prepared by F. D. Dodge (*Amer. Chem. Jour.*, 1889, 11, p. 463) by reducing the corresponding aldehyde (*d*-citronellal). It is an odorous oil which boils at 117–118° C. (17 mm.). Oxidation by chromic acid mixture converts it into citronellal, whilst a more drastic oxidation with potassium permanganate yields acetone and β-methyladipic acid.

l-*Rhodinol*, $C_{10}H_{19}OH$ or $(CH_3)_2C:CH\cdot(CH_2)_2\cdot CH(CH_3)\cdot(CH_2)_2\cdot OH$, or 2·6 dimethyl-octene-2-ol-8, occurs in the essence of geranium and of rose. It is a structural isomer of citronellol (P. Barbier and L. Bouveault, *Comptes rendus*, 1896, 122, pp. 529, 673; *Bull. Soc. Chim.*, 1900, [3], 23, p. 459), and its inactive form has been synthesized from ethyl heptenone. It is an oil of strong rose odour, which boils at 110° C. (10 mm.). Chromic acid mixture oxidizes it to rhodinal and rhodinic acid, whilst by drastic oxidation it yields acetone and β-methyladipic acid.

Geraniol, $C_{10}H_{17}OH$, or $(CH_3)_2C:CH\cdot(CH_2)_2\cdot C(CH_3):CH\cdot CH_2OH$, 2·6 dimethyl-octadiene-2·6-ol-8, is found in the oils of geranium, citronella, neroli, petit-grain, spike, ylang-ylang, and in Turkish and German rose oil. It is prepared from the oils by treating them with alcoholic potash and then fractionating *in vacuo*. The geraniol fraction is then mixed with freshly dried calcium chloride and the mixture allowed to stand *in vacuo* at a low temperature, when the compound $C_{10}H_{18}O\cdot CaCl_2$ separates out. This is washed with absolute ether and finally decomposed by water, when pure geraniol is liberated (O. Jacobsen, *Ann.*, 1871, 157, p. 232; J. Bertram and E. Gildemeister, *Jour. prak. Chem.*, 1897 (2), 56, p. 507). It may also be prepared by reducing the corresponding aldehyde (citral) with sodium amalgam. It is a colourless, pleasant-smelling oil, which boils at 230° C. Oxidation converts it into citral and geranic acid, $(CH_3)_2C:CH\cdot(CH_2)_2\cdot C(CH_3):CH\cdot CO_2H$. By shaking it with 5 per cent. sulphuric acid it yields terpin hydrate, and when heated with concentrated alcoholic potash to 150° C. it is converted into dimethylheptenol (P. Barbier, *Comptes rendus*, 1899, 128, p. 110). Geraniol may be converted into linalool by distilling a faintly alkaline solution of acid geranyl phthalate with steam.

Nerol, $C_{10}H_{17}OH$, was obtained in 1902 from neroli oil by A. Hesse and O. Zeitschel (*Jour. prak. Chem.*, 1902 (2), 66, p. 481); it also is found in petit-grain oil. It boils at 226–227° C. (755 mm.), and has a distinctive rose odour. It is inactive and is to be regarded as a stereo-isomer of geraniol. It does not form a compound with calcium chloride. It combines with four atoms of bromine to form a characteristic tetrabromide. It is formed (along with other products) by the action of acetic acid on linalool (O. Zeitschel, *Ber.*, 1906, 39, p. 1780) and also by the reduction of citral-*b*.

Linalool, $C_{10}H_{17}OH$, or $(CH_3)_2C:CH\cdot(CH_2)_2\cdot C(CH_3)(OH)\cdot CH:CH_2$, is 2·6-dimethyloctadiene-2·7-ol-6. *d*-Linalool was first found in coriander oil, and *l*-linalool in oil of linaloe. It is also found in oil of bergamot, petit-grain, lavender, neroli, spike, sassafras leaves and lemon, either in the free condition or as esters. It is a pleasant-smelling liquid which boils at 197–199° C. (according to its source). The inactive variety can be prepared from geraniol, this alcohol on treatment with hydrochloric acid yielding a mixture of chlorides, which when digested with alcoholic potash are transformed into *i*-linalool (F. Tiemann and F. W. Semmler, *Ber.*, 1898, 31, p. 832). It is oxidized by chromic acid to citral. When shaken for some time with dilute sulphuric acid it yields terpin hydrate.

Citronellal, $C_{10}H_{18}O$, is the aldehyde of citronellol. It is a constituent of many essential oils, and was first discovered in citronella oil by F. D. Dodge (*Amer. Chem. Jour.*, 1889, 11, p. 456); it is also found in eucalyptus oil and in lemon-grass oil. It is a dextrorotatory liquid which boils at 203–204° C. It is readily reduced by sodium amalgam to citronellol, and oxidized by ammoniacal silver oxide to citronellic acid. Potassium permanganate oxidizes it to acetone and β-methyladipic acid. It forms a dimethyl acetal, $C_{10}H_{18}(OCH_3)_2$, which on oxidation with potassium permanganate yields a dioxydihydro-citronellaldimethyl acetal,

$$CH_3\cdot C(CH_2OH)(OH)\cdot(CH_2)_3\cdot CH(CH_3)\cdot CH_2\cdot CHO,$$

which must possess the above composition, since on further oxidation by chromic acid it yields a keto-aldehyde of the constitution $CH_3CO(CH_2)_3\cdot CH(CH_3)\cdot CH_2\cdot CHO$ (C. D. Harries and O. Schauwecker, *Ber.*, 1901, 34, p. 2981); this reaction leads to the formulation of citronellal as a dimethyl-2·6-octene-1-al-8. Citronellal is readily converted into an isomeric cyclic alcohol *isopulegol* ($\Delta 8(9)$-terpenol-3) by acids or acetic anhydride (F. Tiemann, *Ber.*, 1896, 29, p. 913). It combines with sodium bisulphite, giving a normal bisulphite and also a mono- and dihydrosulphonic acid.

Geranial (citral), $C_{10}H_{16}O$, is the aldehyde corresponding to geraniol. It occurs in the oils of lemon, orange, lemon-grass, citronella, bay, verbena, and in various eucalyptus oils. It may be obtained from the oils by means of its bisulphite compound, provided the operation is carried out at low temperature, otherwise loss occurs owing to the formation of sulphonic acids. Synthetically it may be produced by the oxidation of geraniol with chromic acid mixture, or by distilling a mixture of calcium formate and calcium geraniate. Its aldehydic nature is shown by the facts that it forms an alcohol on reduction, and that on oxidation it yields an acid (geranic acid) of the same carbon content. The position of the ethylene linkages in the molecule is proved by the formation of addition compounds, by its products of oxidation (acetone, laevulinic acid), and by the fact that on warming with potassium carbonate solution it yields methyl heptenone and acetaldehyde (F. Tiemann, *Ber.*, 1899, 32, p. 107). On fusion with potassium bisulphate it forms para-cymene. It combines with β-naphthylamine and pyruric acid, in alcoholic solution, to form the characteristic citryl-β-naphthocinchonic acid, $C_{23}H_{23}NO_2\cdot\frac{1}{2}H_2O$, which is useful for identifying citral. The crude citral obtained from essential oils is a mixture of two ethylene stereoisomers which are designated as citral-*a* and citral-*b* (F. Tiemann and M. Kerschbaum, *Ber.*, 1900, 33, p. 877). Citral-*a* boils at 110–112° C. (12 mm.) and citral-*b* at 102–104° C. The structural identity of the two forms has been confirmed by C. Harries (*Ber.*, 1907, 40, p. 2823), who has shown that their ozonides (prepared from the citrals by the action of ozone on their solution in carbon tetrachloride) are quantitatively decomposed in both cases into acetone, laevulinic aldehyde and glyoxal. Lemon-grass oil contains 73 per cent. of citral-*a* and 8 per cent. of citral-*b*. Citral combines with sodium bisulphite to form a normal bisulphite compound, a stable dihydrosulphonate, an unstable dihydrosulphonate and a hydromonosulphonate (F. Tiemann, *Revue gén. de chim. pure et appl.*, 1, 16, p. 150). Citral condenses readily with acetone, in the presence of alkalis, to form pseudo-ionone (see *Ionone*, below).

The compounds of the citral series are readily converted into cyclic isomers by acids, the ring closing between the first and sixth carbon atoms in the chain. Two series of such compounds exist, namely the α and β series, differing from each other in the position of the double linkage in the molecule. The constitution of the α-series is determined by the fact that on oxidation they yield isogeronic acid, which can be further oxidized to $\beta\beta$-dimethyladipic acid; the β-series in the same way yielding geronic acid and $\alpha\alpha$-dimethyladipic acid. The *cyclo*citrals themselves cannot be obtained direct from citral by the action of acids, since under these conditions para-cymene results, but they are prepared by boiling citrylidenecyanacetic ester with dilute sulphuric acid and subsequent hydrolysis of the cyclic ester with caustic potash (F. Tiemann, *Ber.*, 1900, 33, p. 3719), or citral may be condensed with primary amines to the corresponding aldehydeimino compounds, which are then isomerized by concentrated acids, the amine group being hydrolysed at the same time (German Patent, 123747 (1901)).

Ionone, $C_{13}N_{20}O$. By condensing citral with acetone F. Tiemann (*Ber.*, 1893, 26, p. 2691) obtained pseudo-ionone (1), an oil of boiling-point 143–145° C. (12 mm.), which on boiling with sulphuric acid is converted into a mixture of the isomeric α- and β-ionones (2 and 3)

(1) $(CH_3)_2C:CH\cdot(CH_2)_2\cdot C(CH_3):CH\cdot CH:CH\cdot CO\cdot CH_3$

(2) 
(3) 
α-Ionone is an oil which boils at 127–128° C. (12 mm.) and possesses a characteristic violet odour. The β-compound boils at 128–129° C. (10 mm.) and possesses a similar odour. They are largely used in perfumery. An isomer of ionone is irone, the odoriferous principle of the iris root. It boils at 144° C. (16 mm.). When heated with hydriodic acid and phosphorus it yields the hydrocarbon irene, $C_{13}H_{18}$ (F. Tiemann, *loc. cit.*).

Sesquiterpenes

Cadinene, $C_{15}H_{24}$, is found in the oils of cade (from the wood of *Juniperus oxyeldrus*), cubeb, patchouli, galbanum, cedar-wood and juniper. It may be obtained by fractionating oil of cade, converting the crude hydrocarbon into its dihydrochloride and decomposing this by boiling with aniline. It is an oil which boils at 274–275° C. and decomposes on exposure. *Caryophyllene* is found in oil of cloves and in oil of copaiba balsam. Various other sesquiterpenes have been described, *e.g.* zingiberene (from essence of ginger), cedrene (from oil of cedar-wood), santalene (from oil of sandal-wood), humulene and clovene.

Of the sesquiterpene alcohols pure *santalol*, $C_{15}H_{26}O$, has been obtained from essence of sandal-wood by conversion into the acid phthalic esters and saponification of these by potash (Schimmel & Co., *Bulletin*, April 1899, p 41). A mixture of two alcohols is thus obtained, one boiling at 165–167° C. (13 mm.) and the other at 173° C. They are distinguished by their different optical activities, one being practically inactive, the other strongly laevo-rotatory (see also M. Guerbet, *Comptes rendus*, 1900, 130, p. 417; *Bull. Soc. Chim.*, 1900 (3), 23, p. 540). Caryophyllene alcohol is obtained from oil of cloves; by elimination of water it yields clovene, $C_{15}H_{24}$, a liquid which boils at 261–263° C.

Many di- and tri-terpenes have been described, but as yet are not thoroughly characterized.

TERRACE (Fr. *terrace*, *terrasse*, from It. *terraccia*, *terrazza*, Lat. *terra*, earth), a raised platform of earth; in geology the term is used of level horizontal ridges on the side of a slope, formed by volcanic action, or more usually by the action of water; they are thus frequent along the shores of lakes or by rivers; on the sea-shore they are generally known as "raised beaches." The term is used in architecture of an artificial platform in front of a building, which is utilized as a promenade; sometimes, when the building is erected on an elevation, there may be a series of terraces rising one above the other, with flights of steps leading from one to the other, as in the Villa D'Este at Tivoli; or there may be a single terrace raised high above the ground and supported on arches, as the terrace to the Adelphi buildings in the Strand, or the river front at Somerset House, or in France at the castles at Amboise and St Germain-en-laye, or again a low terrace like that in front of the Houses of Parliament at Westminster overlooking the Thames, which is 670 ft. long and 35 ft. wide. The terraces of the gardens at Isola Bella on the Lago Maggiore are known as hanging gardens (*Hortus pensilis*), and were similar to those which were built by the Assyrian king at Babylon. Though properly applied to a row of buildings on a raised level, the word is often used of any row of houses.

TERRACINA (Lat. *Tarracina*, Volsc. *Anxur*), a town and episcopal see of the province of Rome, Italy, 76 m. S.E. of Rome by rail (56 by the Via Appia), 40 ft. above sea-level. Pop. (1901) 7597 (town), 10,995 (commune). Its position, at the point where the Volscian Hills reach the coast, leaving no space for passage between them and the sea, commanding the Pomptine Marshes (*urbs prona in paludes*, as Livy calls it) and possessing a small harbour, was one of great strategic importance; and it thus appears very early in Roman history. It appears in 509 B.C. as under Roman supremacy, but is not included in the list of the Latin league of 499 B.C. In 406 it was stormed by the Romans, lost in 402, recovered in 400, unsuccessfully attacked by the Volscians in 397, and finally secured by the establishment of a colony of Roman citizens in 329 B.C. As such it frequently appears in history. The construction of the Via Appia in 312 B.C. added to its importance: the road at first crossed the hill at the back of the promontory by a steep ascent and descent. An attempt was made in 184 B.C. to get round it by an embankment thrown out into the sea: but it was probably not until early in the imperial period that a cutting in the rocks at the foot of the promontory (Pisco Montano) finally solved the problem. The depth of the cutting is indicated by marks on the vertical wall at intervals of 10 Roman ft.—figures enclosed in large swallow-tail tablets—the lowest mark, 3 or 4 ft. above the present road, is CXX. Not far off are mineral springs by the coast (*Neptuniae aquae*), known to the Romans and still in use—except one containing arsenic which was blocked up both by the ancients and again in 1839 as a precaution. The two roads met some few miles E. of Tarracina, and the Via Appia then traversed the pass of Lautulae, between the mountains and the Lake of Fondi, where the Samnites defeated the Romans with loss in 315 B.C. This pass, the frontier between the Papal States and the kingdom of Naples, was also fortified in modern days. It was probably in consequence of the cutting just mentioned that some of the more important buildings of the imperial period were erected in the low ground by the shore, and near the small harbour. The construction of the coast road, the Via Severiana, from Ostia to Tarracina, added to the importance of the place; and the beauty of the promontory with its luxuriant flora and attractive view had made it frequented by the Romans as early as 200 B.C. Galba and Domitian possessed country houses here. It appears in the history of the Gothic wars, and Theodoric is said to have had a palace here. It was sacked in 409 and 595. In 872 John VIII. brought it under the domination of the Holy See.

The picturesque modern town occupies the site of the old; the present piazza is the ancient Forum, and its pavement of slabs of travertine with the inscription "A. Aemilius A. F.," in letters once filled in with bronze, is well preserved. It is supported by massive arched substructures, which extend under the surrounding houses. The cathedral of SS. Pietro e Cesareo, fronting upon it, is ensconced in a temple of Rome and Augustus, part of the side wall of which, with engaged columns, is still visible. The vestibule, in the Cosmatesque style, is supported by ten ancient columns resting upon recumbent lions, with a mosaic frieze upon them. The brick campanile has small columns with little pointed arches. The interior has a fine Cosmatesque pulpit supported by ancient columns resting on lions, a Paschal candlestick of 1245, and a good pavement of the same period with beasts and dragons. The sacristy contains a carved wooden nuptial chest of the 10th or 11th century. There are also remains of the town wall in the "polygonal" style, and above the town are several massive platforms for supporting buildings, in a more archaistic form of this style; these may well belong to the Roman period, and the latter even to the empire. The summit of the promontory (748 ft.) is reached by the old line of the Via Appia, which is flanked by tombs and by remains of an ancient defensive wall with circular towers (currently attributed to Theodoric, but probably a good deal earlier in date). The summit is occupied by a massive terrace, supported by arcades of fine *opus incertum* (traditionally, but wrongly, called the palace of Theodoric) on all sides except the E., and commanding a magnificent view seaward over the coast and over the Pomptine Marshes. On the terrace, as was ascertained in 1894, stood a Corinthian temple of the early imperial period, 110 by 65 ft.; the cella was decorated internally with engaged half-columns, and contained the pedestal for the statue of the deity, according to some authorities Venus, but more probably Jupiter Anxur worshipped as a child—a theory confirmed by the discovery of many curious leaden toys, like those made for dolls' houses at the present day, in the *favissae* on the E. of the temple. Of the lower town by the harbour, which had buildings of some importance of the imperial period (amphitheatre, baths, &c.), little is now visible, and its site is mainly occupied by a new quarter built by Pope Pius VI., who restored the Via Appia through the Pomptine Marshes. Close by it in the S.W. is a group of huts inhabited in winter by labourers from the Abruzzi, as is the case in many other parts of the Campagna. Of the ancient harbour constructed by Antoninus Pius (M. R. de la Blanchère in *Mélanges de l'école française de Rome*, i. 322; 1881) insignificant remains exist, and it is largely silted up. Close to it is the small modern port. Near the amphitheatre was found in 1838 the famous statue of Sophocles now in the Lateran museum. The commune of Terracina includes a considerable extension of territory towards the N.W. with much undergrowth (*macchia*) valuable for charcoal burning, and a considerable extent of pasture and arable land. The ancient aqueduct, bringing water some 35 m. from the slopes of the Volscian Hills, has been repaired and is in use. Three miles to the N.W., at the foot of the Monte Leano, was the shrine of the nymph Feronia, where the canal following the Via Appia through the marshes ended. Along these 3 m. of the Via Appia are numerous ancient tombs, and the fertile valley to the N.E. was thickly populated in Roman days.

See M. R. de la Blanchère, *Terracine* (Paris, 1884). (T. As.)

TERRACOTTA. *Greek.*—The use of clay amongst the Greeks was very varied and extensive, but we are here only concerned with one aspect of it, that in which the clay was baked without any glaze, whether employed for utilitarian or ornamental purposes. The Greek term for this is γῆ ὀπτή, "baked earth"; the word πηλός when applied to worked clay signifies "sun-dried" only. Among the manifold purposes to which terracotta was put by the Greeks may be mentioned parts of public and private buildings, such as bricks, roof tiles, drain and flue tiles, and architectural ornaments; tombs and coffins; statues and statuettes, for votive or sepulchral purposes or for the decoration of houses; imitations of metal vases and jewelry; and such everyday objects as spindle whorls, theatre tickets, lamps, braziers and domestic utensils. It also supplied the potter with moulds and the sculptor with models of works of art, especially in bronze.

Use in Architecture.—In architecture terracotta was extensively employed for roof tiles and other decorative details, as has been shown by many recent discoveries, especially at Olympia. In the Heraion we have the oldest example of a terracotta roof. A 6th-century temple at Thermon in Acarnania is also constructed of wood and terracotta, with painted terracotta slabs in wooden frames for metopes. The generic term for a roof tile was *κέραμος*, and these are classified as flat square tiles (*στεγαστῆρες* or *σωλῆνες*) and semi-cylindrical covering tiles (*καλυπτῆρες*). Other varieties of ornamental tiles used in buildings are (1) the covering slabs along the raking-cornice (*γεῖσον*) of the pediment; (2) the *κυμάτιον* or cornice above the *γεῖσον*; (3) the cornice along the sides with lions' head spouts to carry off rain-water; (4) the *ἀκρωτήρια* or antefixal ornaments surmounting the side-tiles. These latter varieties were usually enriched with decoration in colour, the *κυμάτιον* being painted with elaborate patterns of lotos-and-honeysuckle or Greek key-pattern, in red, blue, brown and yellow, curvilinear patterns being restricted to curved, rectilinear to flat surfaces. The antefixal ornaments were usually modelled in the form of an anthemion or palmette, but were sometimes adorned with reliefs or sculptured groups, as in the case of the temple of Zeus at Olympia, which has figures of Victory along the cornice. The British Museum has an interesting series of 6th-century date from Capua, with gorgons' heads, female busts, and other subjects in relief, and others come from an early 5th-century temple at Civita Lavinia. Many coloured roof tiles have been found at Olympia.

In Sicily and southern Italy a fashion prevailed of nailing slabs of terracotta over the surface of the stonework (a legacy from the epoch of wooden buildings which required protection from the weather). These were ornamented with lotos-and-honeysuckle and other patterns, sometimes in relief but always richly coloured. They occur at Olympia in the Treasury of Gela, by a Sicilian architect, and also in a temple at Selinus. The best example of this practice is the temple at Civita Lavinia already cited, the remains of which belong partly to the 6th, partly to the 4th century B.C.

Sculpture.—The subject of Greek sculpture in terracotta is a large one, and only its brief outlines can be given here. Of large or life-size statues comparatively few examples are known, and they can only be said to be common in Cyprus, where marble was difficult to procure; they are also more frequent in Italy, as will be seen later. But the use of clay for the reproduction of the human figure was one of the earliest instincts of the race, and may be traced back as far as archaeological records exist, to the days of the Minoan and Aegean supremacies. Terracotta figures of a very primitive character have been found in Crete, in Melos and at Olympia, and one series of figures from Petsofa in Crete is remarkable for the very modern fashions of head-dress and costumes. Terracotta figures of more advanced style have also been found in Rhodes and other places dating from the Mycenaean period.

Greek traditions on the subject go back to one Butades of Sikyon, a potter who was credited with the invention of modelling clay in relief; and the Samian sculptors Theodorus and Rhoikos, who lived about the end of the 7th century B.C., were said to have been the first to use clay models for statues. As they were supposed to have introduced hollow casting in bronze, it was obviously for this purpose that they employed clay. But this material was later superseded by wax, and for marble statues was not used until Roman times.

The small terracotta figures used as ornaments or household gods, buried in tombs or dedicated in temples, trace their pedigree from the prehistoric examples already mentioned. They have been found in large numbers on nearly all the well-known sites of antiquity, the most fruitful being Tanagra in Boeotia, Myrina in Asia Minor, Rhodes, the Cyrenaica, Athens, Sicily, and some of the towns of southern Italy. They are also found in Cyprus and Sardinia, where, as to some extent in Rhodes, they follow a peculiar development, under the domination of Phoenician influence, and many of the earlier types have a markedly oriental character. But in the Greek terracottas we may trace a steady development from the primitive types which correspond to the *ξόανα* of primitive Greek religion, and for the most part represent actual deities, down to the purely *genre* figures of Tanagra and other Hellenistic products of highly-developed beauty. For beauty and charm the palm has by general consent been given to the Tanagra figures of the 4th and 3rd centuries B.C. which were known in antiquity as *κόραι* or "maidens," from the presence of seated or standing types of girls in various attitudes. The makers of these figures were known as *κοροπλάσται* or *κοροπλάσοι*, and are spoken of in literature, together with their wares, with some contempt.

Manufacture.—The processes employed in the manufacture of terracottas are five in number: (1) the preparation of the clay; (2) moulding; (3) retouching; (4) baking; and (5) colouring and gilding. The last named, though not essential, was almost universal in some form or another.[1]

The clay used for the statuettes varies greatly in different localities, and this is an important criterion for distinguishing the different sites of manufacture. It ranges in colour from a deep red (as in the brick-like terracottas of Naukratis) to a pale buff or drab as in Cyprus, and the fired product is generally softer than that of the painted vases. It was prepared by washing the local clay free from all granular substances and then kneading it with the aid of water. The modelling was done by hand in the case of the earlier figures, and small objects such as toys and dolls, which are solid; the clay was worked up into a mass with the fingers, the marks of which may often be seen. Subsequently the use of moulds became universal, the final touches being given to the figure either with the fingers or with a graving tool. The finer statuettes, such as those of Tanagra, are invariably moulded, and the better examples show traces of very careful retouching. The advantage of moulding was that the "walls" of the figure could be reduced to a very regular thickness, obviating the danger of shrinkage in the baking; it also rendered them very light, and permitted great accuracy in detail. A model (*πρότυπος*) was first made in terracotta with modelling tools, from which the mould (*τύπος*) was taken, also in terracotta and usually in two pieces, which were then baked to a considerable hardness. From this mould the figure was made by smearing it with layers of clay until a sufficient thickness was reached, leaving the figure hollow. The back was made separately, either from a mould or by hand, and then fitted carefully to the front, the seam or join being run up with soft clay. The base was usually left open, and a vent hole was left in the back, which aided the clay to dry and to be re-fired without cracking, and was also used sometimes for suspending the figure when finished. The heads and arms were usually moulded separately, and attached or luted to the body with soft clay. Greek moulds for statuettes are somewhat rare, but there are examples known from Kertch, Smyrna, Girgenti and Tarentum; the British Museum has a series from the last-named site (Pl. I. fig. 3). Most of these are for small figures only.

The shrinkage of the clay as it dried permitted the figure to be drawn easily from the mould, and the reproduction was then ready for retouching. It is obvious, from a glance at any collection of terracottas, that there is a great similarity between the various examples of any one type, and that many are virtually, if not actually, replicas of one another. This of course was due to the fact that only a limited number of moulds were used, corresponding to the various types. The minute differences between them, which constitute the charming variety found amongst these figures, and prevent monotony even where the type is constant, were obtained by the process of retouching, as well as by varying the pose of the head or limbs, or by differences of attributes and colourings. Actual retouching by a skilled modeller is seldom found except in the finer examples.

The process of baking required great care and attention, for if no allowance were made for the evaporation of moisture, or if too great a degree of temperature were reached, the result was disastrous. The clay was ensured against drying too rapidly by preliminary exposure to air and sunshine, while the temperature employed in firing was low even lower than that used for painted vases.

The colouring of the baked statuettes was fairly universal, the chief exceptions being some of the more archaic examples, and many of the Roman period. The surface on which the colours was laid was formed by a white slip or *engobe* of a creamy colour and consistency, with which the whole front of the figure was coated. This when dry became very flaky and has often fallen off, carrying the colours with it, though most statuettes retain at least traces of this treatment with slip. It is very unlikely that this slip-coating was fired at all. On the white slip-facing opaque

[1] Clever forgeries of Greek terracotta figures are now being produced both in France and Italy. Admitted copies are also made in Berlin and Vienna, but these are generally so inferior in artistic merit as not to deceive any one who knows the genuine article.

colours were painted in *tempera* colours. The colouring was usually conventional, and only aimed at imparting a pleasing appearance to the figure. It was necessarily applied after the firing, as many of the pigments used would have been altered or destroyed at the firing temperature of the body. The tints were body-colours, applied without shading, and red, blue, yellow and black are those most commonly employed, the white slip serving for the nude parts and generally also for the ground-work. Blue and red were especially favoured for drapery, as in many of the Tanagra figures; the red ranging from scarlet to pink or rose purple. Black was only used for the eyes or details of features; yellow (varying to deep brown) for the hair, and also for jewelry. Gilding is rare but was frequently employed in later times for terracotta imitations of jewelry. In the primitive terracottas and those of Cyprus or other centres which adhered to primitive methods, the decoration is in stripes of *matt* black and red paint applied in a conventional manner to human figures and animals alike. True glazes or enamels are occasionally found, as for instance in the later terracottas of Sicily, where they are employed both for drapery and for flesh colours.

Greek terracotta statuettes have been discovered in tombs, on the sites of sanctuaries, and in private houses. The tomb-finds are scattered all over the Mediterranean littoral, and the chief sites have already been noted; among the sanctuaries we may cite Olympia, the Acropolis at Athens, the *temenos* of Demeter at Knidos, the temples at Naukratis in the Egyptian Delta, many sites in Cyprus, and temples at Selinus in Sicily and Tarentum. The purposes for which these statuettes were used, (*a*) for religious rites, (*b*) in daily life, (*c*) in funeral ceremonies, have been the subject of much debate. Since the same types and subjects are common to each of these classes of discoveries it is obvious that the terracottas cannot have been intended for one purpose alone even if their primary significance was religious. Numerous theories have been advanced on this subject, some authorities having maintained that their meaning was exclusively religious or mythological, that they originally corresponded to the Egyptian *ushabti*, and that these religious types were afterwards adopted for ordinary human figures symbolizing the life of the deceased beyond the tomb. The gradual change in popular taste from figures of deities to figures of a *genre* type is unquestionably a feature of the development of this branch of art, but that the development was affected by religious ideas is more open to doubt. It is more probable that it followed the lines of artistic evolution, and that the continued use of terracottas as votive or funeral offerings became more or less a convention. In fact, the identity of the types, under whatever circumstances they are found, seems to indicate that the significance was given to them by the purchaser, who would decide for himself whether he offered them to some appropriate deity, deposited them in the tomb of some relative, or kept them for use and decoration in his own house.

Subjects and Types.—The earliest beginnings of the statuettes proper show, as might be expected in primitive Greek art, a very limited range of subjects. As in other materials, so also in clay, the female deity reigns supreme. The primitive Hellenic type of goddess adopts two forms, both derived from an original in wood, the board-form *σανίς*, and the column form *κίων* or *ξόανον*, both of which we find also in sculpture. The limbs are wanting, or are at best rudimentary, the figure terminating below in a spreading base. Both types are found in Rhodes, but on the mainland of Greece the columnar type died out after the Mycenaean period, and only the board-type remained, this being specially popular in Boeotia, where both standing and sitting figures occur, painted in the same style as the local vases. This type was adhered to for the bodies of figures even when the head was modelled in a more advanced style of art. The column-type is also well exemplified in Cyprus. The standing and seated goddesses are the two principal types in archaic Greek art (Pl. II. fig. 4), and are widely distributed and of universal popularity; though the conception of the goddess may vary with the locality, the types are almost identical, and the attributes are but slightly varied. A certain proportion of these deities are differentiated as nature-goddesses, either as a nude goddess in a shrine or a seated figure with a child in her lap who may be described as the Earth-Mother. Both types are of oriental origin. Another common archaic type is the funeral mask or bust, hollow at the back, which is found both in central Greece and Rhodes. Being almost always feminine it seems probable that these are not images of the deceased, but the Chthonian goddesses Demeter and Persephone, playing in the tombs the rôle of protectress against evil influences. We may also mention here the little figures of animals, women and children variously occupied, and jointed dolls (*νευρόσπαστα*) which can only have served the purpose of children's toys. In Athens, Melos and Rhodes, many of these have been found in children's graves. The evidence of finds and other indications seems to show that these archaic types were not affected by the rapid development of Greek art in the 5th century, but continued in vogue until the end of that period. Certainly there are very few terracottas of developed style which can be assigned to an earlier period than the 4th century, and many figures of archaic type can be shown from the contents of the tombs in which they are found not to be earlier than the 5th century B.C. The reason for this is probably hieratic. Owing to their religious associations old conventional types continued in use, whereas painted vases and the majority of sculptures of a higher class were not affected by such considerations. Therefore we are not surprised when we come to the later terracottas of the fine period, or 4th century, to find the standing and seated feminine types still prominent. But the change in style is also accompanied by a change in conception, and in place of the goddess we now have the Greek lady—in place of the mythological the *genre*. The transformation was quite a simple one, and it needed little change to convert a nursing goddess into a mother with her little one, or a Persephone holding a flower into a girl of Tanagra. The change in fact was artistic rather than religious; an evolution rather than a revolution. The figures were still placed in tombs and shrines, though the old associations were less strongly felt.

In order to know what were the characteristics of the best Greek work in terracotta we must turn our attention to its most typical products, the Tanagra statuettes (Pl. II. fig. 4). Here we have an almost unlimited variety of feminine figures illustrating the daily life of Greek women. In most cases the arms are more or less concealed by the mantle which is drawn closely across the figure, even covering the hands; but many hold a fan, a mirror, a wreath, or a theatrical mask in one hand, while with the other they gather together the folds of their draperies. The long tunic or *chiton* and the mantle or *himation*, which all without exception wear, formed the typical dress of the Greek matron and girl; and to this was added for outdoor wear a large shady hat. The seated types follow on the same lines, but are not so common. These figures range in date from about 350 to 200 B.C., and their inspiration is probably drawn rather from the painting than the sculpture of the period. The terracottas of Eretria in Euboea and of Myrina in Asia Minor stand next in artistic merit, but are of more markedly Hellenistic character; they are freer from ancient tradition, but tend to degenerate into exaggeration of pose and conception. Here the types of divinities so conspicuously absent at Tanagra reappear; in particular Eros or Cupid, the one deity who universally caught the popular taste in the Hellenistic age, and in the many representations of whom we see the prototypes of the Pompeian Amoretti; Aphrodite, Dionysos and Victory are also popular themes. At some times the Tanagra types are repeated here, as, with varying artistic success, in other parts of the Mediterranean littoral.
